Most social surveys carried out in the territories common to social medicine and psychiatry have somewhere in the background a utilitarian aim: their results are expected to point the way towards social improvements. There are three possible objectives, which present themselves in a certain order, like lines of trenches to be captured. The first is the ascertainment of the gross incidence of the condition under investigation, or of its differential incidence, or, if possible, its trend. Thus Dr. Lewis was concerned with the gross incidence of mental defect in England and Wales, with its differential incidence in town and country, and with trends during the preceding twenty years. Prof. Strömberg was concerned with the total incidence of psychiatric abnormalities in Bornholm, and with the average expectation there of various forms of mental illness. His survey has something in common with that instituted in an area of South-West Scotland by Dr. Mayer Gross. The second possible objective of social research is the *cause* or *causes* of the condition under investigation. The Mental Deficiency Committee, to which Dr. Lewis made his report, had something to say about the familial incidence of the higher grades of defect; and Prof. Strömberg was concerned with the genetical character of some of the disorders he surveyed. The third objective is *remedial*: it supplies an answer to the questions, Up to what limits can improvements be made? and, How much can we reasonably expect to do?

An answer to the question, How much can we reasonably expect to do? can be gained from inquiries into differential incidence. Thus the fact that rheumatic fever, infantile deaths, and stillbirths are of relatively scarce incidence among people living in socially favoured conditions provides us with a vision of a goal which could be attained by social policy. The same can be said for the experiences of other countries. The fact that in 1939 the infant mortality rate for New Zealand was 31 while that for Malta was 227 provides for the Maltese and the rest of us a standard to which we can reasonably aspire. By such comparisons we can also learn something about the causes of infant mortality and also about remedies. When diagnostic terms used in different countries can be matched with each other as closely as can figures for infant deaths, then we shall be better placed than we are to-day to profit from the findings of other countries' surveys.

We in this country are surely on the threshold of a period when the social survey, the pilot inquiry, can be more usefully employed than ever before. The value of pilot investigations was well appreciated by the Nuffield Foundation when this body was concerned with exploring the possibilities of co-operation between the voluntary and municipal systems of hospital administration. How much greater can be their usefulness in the future when the structure of our medical services will be more uniform. Indeed, many will base their judgment of centralized medical services on the extent that universities and other unofficial organizations are encouraged to make pilot investigations. Unofficial bodies have in the past played the part of advance guards, reconnoitring new territories into which, when positions are established, the ponderous main body moves into occupation. The main body has now become large and ponderous: all the more need for scouts, patrols, and guides.

### Conclusion

I began this paper by commenting on how the early American social surveys and our own—the Booth and Rowntree surveys—were concerned with the effects of inequalities in the environment. If hopes are fulfilled by the new order we will witness a narrowing of the gap which separates the over-opulent from the slum home. There will be a general equalizing of those features of the environment which influence health. Differences between human beings will then be better recognized as being partly determined by innate qualities. For man is not only the product of his environment; he is also largely its architect.

Speaking at the Silver Jubilee National Safety Congress organized by the Royal Society for the Prevention of Accidents and held at Brighton from Oct. 6 to 10, Mr. Duguid said that only a few American States—notably New York and California—had safety legislation comparable to that in Great Britain. Other States either had very little legislation or else had laws which were not well enforced. America had nothing to teach us about the fencing of machinery. Dust and fume removal in American factories was good, but general factory ventilation was not. Mr. Tugman said that he went to America to learn what he could about safety methods and therefore visited only the best factories. What he had seen was not necessarily typical of American industry as a whole, but he was satisfied that the best results achieved in America were better than the best results achieved in Great Britain. Making all allowances for different methods of calculation, he had come to the conclusion that in the best American works the accident rate was only one-quarter of the lowest figures recorded in this country. One reason for this was that, in the best firms, the drive from the top was more apparent than in Great Britain, and there seemed to be a greater emphasis on managerial responsibility for accident prevention. More staff was employed to encourage, co-ordinate, and advise on safety at all levels of management. On the subject of protective clothing we did not have much to learn from the U.S.A., and guarding of machinery was not practised to nearly the same extent as in this country.

## CHILD-BEARING AND PULMONARY TUBERCULOSIS

BY

CHARLES J. STEWART, M.D., D.R.C.O.G.

*Assistant Physician, Uxbridge Chest Clinic*

AND

F. A. H. SIMMONDS, M.A., M.D., D.P.H.

*Medical Director, Clare Hall County Sanatorium, Middlesex*

Just how commonly do pregnancy and tuberculosis occur together? Routine radiography and screening of women attending antenatal clinics show that the rate of incidence of pulmonary tuberculosis is no greater among pregnant women than among others in the same age group (Nicolson, 1946; Jacobs, 1946; Dawson, 1945).

Rich (1944) estimates that in America one woman in eight of those aged between 15 and 30 years is pregnant at any given moment. A similar estimate for the population of Middlesex for the years 1943–4 shows that of women in child-bearing age (15 to 45) 1 in 12 to 1 in 16 were delivered of children in each year. The peak incidence of tuberculosis in females occurs during the same age period, hence it is clear that chance alone will ensure that a considerable number of women will be pregnant in a reasonably close time-relationship to the onset or course of a tuberculous illness. It is therefore wise to admit an aetiological association only if it is established that tuberculous disease is more frequent in women who have gone through pregnancy than in an otherwise comparable group. Such a comparison is in practice extremely difficult.

If the estimates given above hold for the whole of Britain it would seem that 2,000 to 3,000 tuberculous women become pregnant each year. The only large series of cases reported recently in this country is from the special unit for pregnant tuberculous women at Black Notley (Cohen, 1946). Because of the paucity of reliable information on the subject it was decided at a meeting of the Middlesex Tuberculosis Association in January, 1944, to keep a central register of pregnancies occurring in women attending chest clinics in the county. It was from this register that the present series of cases was obtained, and from the records of the clinic that the information regarding the patients was collected.

No attempt will be made here to review the extensive literature, as several recent summaries and reviews are available (Friedman and Garber, 1946; Cohen, 1946; Oxenham, 1941; and Brooks, 1940).

### Object of Investigation

Our aim was to determine what influence, if any, "child-bearing" has upon the course of pulmonary tuberculous disease in patients already diagnosed as suffering from pulmonary tuberculosis and those whose disease was found during the early months of pregnancy.

A deliberate distinction is made between "child-bearing" and "infant-rearing." By the former is understood the physiological process of conception, maturation of the foetus, and parturition, with the associated metabolic, endocrine, and mechanical changes in the mother. Rearing of an infant includes its care and nutrition. The early months after the birth of the child call for much effort from the average mother—extra washing, preparation of feed and sleepless nights often causing a state of tension and anxiety. Common to both these periods for most women are the normal household duties, including shopping; so the period surveyed here these were even more arduous than in peacetime. No attempt is made here to assess the

strain of rearing an infant. It must be admitted that it is difficult to separate these functions precisely: the puerperium, really a part of the child-bearing process, coincides with the early days of the period of rearing. For the above reasons the state of the disease was assessed as near to the beginning of pregnancy as available records allow; this state was then compared with the state three to six months after parturition.

### Material

#### Pregnant Cases

The estimated population of Middlesex for the period of the investigation was 1,900,000; at that time (1944) there were about 4,200 tuberculous females of child-bearing age on the registers of the chest clinics.

From January, 1944, a record of all cases of pregnancy occurring in females with pulmonary tuberculosis attending the chest clinics was kept. Up to June, 1946, 160 women were known to have completed full-time pregnancies, plus post-partum observation period of six months; 23 of these had embarked upon a second pregnancy. There were also 56 women who had had their pregnancies terminated surgically. With the 20 patients who were lost sight of this gives a total of 236 single pregnancies in a period of 18 months, allowing 15 months for the period of assessment (Table I). These patients were considered in two broad

TABLE I

Stage of Tb.	Pregnant	Non-pregnant
Arrested or quiescent .. ..	166 (70.3%)	125 (38.9%)
Active or progressive .. ..	50 (21.2%)	114 (35.5%)
Records inadequate .. ..	20 (8.4%)	82 (25.6%)
Total .. ..	236	321

groups: (1) those with quiescent and arrested disease, totaling 166; and (2) those with active disease (50), including progressive or advanced lesions and unstable but less severe disease. Patients who were "recovered"—that is, written off the clinic register after at least five years of quiescent disease—were excluded, as were patients moved from the county during the period of the inquiry. In Table I these latter cases are included in the line marked "records inadequate."

#### Controls

In assessing any group of tuberculous patients the question of controls is always a thorny one, and with the added complication of pregnancy the difficulties are in no way eased. Forssner *et al.* (1924), and many workers subsequently, were of the opinion that an adequate control group was impossible to obtain. In the early 1920's Alice Hill (1928) and others attempted it with some degree of success, but their figures would hardly satisfy the statistically minded.

In spite of forebodings aroused by the literature it was decided to try to obtain a control group from the married women of child-bearing age on the register of two of the Middlesex clinics on Jan. 1, 1944; from these were chosen all those who had had no pregnancy between January, 1943, and June, 1946—that is, all patients who might have had pregnancies in relation to the period of observation were excluded. All new patients and those who died in 1944 but who otherwise conformed to the above criteria were included.

There was a total of 321 such cases, 82 of which had to be excluded for various reasons, such as transfer to areas outside Middlesex, or because only inadequate clinical or x-ray records were available, and lastly because some few refused or were unable to attend the clinic for one cause or another. The reason for this disproportionately high number of cases with "inadequate records" among the con-

trols—26% compared with 8% in the pregnant group of patients—was partly due to the fact that the investigation of the pregnant women was planned before the collection of cases; all such cases had clinical and radiological examinations at three-monthly intervals, while the details of the control group of cases had to be collected in retrospect.

These two large groups, composed of 216 pregnant women and 259 non-pregnant women, were compared for (1) age composition, (2) social class, (3) previous pregnancies, (4) duration of disease, and (5) activity or quiescence of disease. It was found that there was no statistically significant difference under headings 2, 3, and 4, but for headings 1 and 5 there was an important distinction between the two groups. After separating the active from the quiescent cases and analysing them separately, comparison of the two active groups then showed that there was no significant difference under headings 1, 2, 3, and 4, while there still remained in the quiescent group a wide difference in the age composition of the pregnant and non-pregnant classes.

### Age Composition

In both "active" and "arrested or quiescent" groups the ages ranged from 18 to 43. There is a marked difference

TABLE II

Age Group	Active		Arrested or Quiescent	
	Pregnant	Non-pregnant	Pregnant	Non-pregnant
Under 30 .. ..	26	52	93	47
Over 30 .. ..	24	62	73	78
Total .. ..	50	114	166	125
$\chi^2=0.552$ ; P: 0.5 to 0.3			$\chi^2=9.458$ ; P<0.01	

in the age distribution of the two "arrested or quiescent" groups (Table II). Suggested reasons for this are given later in the paper.

### Social State and Environment

Middlesex lies to the north and west of London. From a densely populated area bordering London it shades off through typical suburban areas to rural surroundings on the periphery. Largely built upon between the two great wars, it now contains a mixed population derived from its former residents, persons removed from London as a result of slum-clearance schemes, and others from all parts of the British Isles. Many districts have their own industries which absorb the local working population; others are mainly residential and dormitory areas for London.

The period of the investigation covers the latter part of the second world war and the first year thereafter. It was a time when people had to contend with many hardships and restrictions affecting almost all aspects of their daily lives. From June, 1944, to May the following year the area was bombarded from the Continent, causing in many a constant state of anxiety and much loss of sleep. The diet, although possibly adequate in calories, contained the minimum requirements of fat and protein considered necessary for the tuberculous. Tuberculous patients at that time were allowed 14 pints (7.95 litres) of milk a week compared with the healthy civilian's 3 to 5 pints (1.7 to 2.8 litres); pregnant women were also allowed extra meat and approximately two eggs a week, as well as vitamin supplements in the form of orange juice and cod-liver oil.

The social classification used (Table III) was based on broad general lines from reports by welfare officers and health visitors. Patients living in comfortable circumstances and obviously in a position to pay for their treatment in a private sanatorium were classed as good; others living in poverty and overcrowded conditions were classed

TABLE III

Social State	Active		Arrested or Quiescent	
	Pregnant	Non-pregnant	Pregnant	Non-pregnant
Satisfactory or good ..	39	99	143	114
Bad ... ..	11	15	23	11
Total .. ..	50	114	166	125
	$\chi^2=2.936$ ; P: 0.1 to 0.05		$\chi^2=1.465$ ; P: 0.3 to 0.2	

as bad.. The great majority were in the satisfactory group, which contains the "black-coated" and "working-class" categories, and a large percentage had husbands serving in the Forces and were therefore living on Army pay and allowances.

#### Degree of Parity

Table IV shows that the groups are comparable in regard to the degree of parity. Among those who have borne children before it is important to eliminate so far as is

TABLE IV

No. of Previous Pregnancies	Active		Arrested or Quiescent	
	Pregnant	Non-pregnant	Pregnant	Non-pregnant
None .. ..	31	54	97	71
One or more .. ..	19	60	69	54
Total .. ..	50	114	166	125
	$\chi^2=2.798$ ; P: 0.1 to 0.05		$\chi^2=0.694$ ; P: 0.5 to 0.3	

possible any influence that infant-rearing might have upon the present pregnancy. Knowledge of the spacing and frequency of previous pregnancies is essential for an accurate assessment of this factor. As the records inspected did not give this information it was decided to exclude from the present investigation all patients who had had pregnancies during the year prior to the period of assessment; such are included in Table I under "inadequate records," and they amount to less than 2% of the total in both groups.

#### Duration of Disease and Obstetric Details

The duration of the active cases is shown in two-year groupings and for the non-active cases in five-year groupings (Tables V and VI). As is only to be expected, the non-active cases show greater chronicity than the active cases.

TABLE V

Duration of Disease in Years	Active Disease	
	Pregnant	Non-pregnant
0-1 .. ..	23	55
2-3 .. ..	13	35
4-5 .. ..	7	12
6+ .. ..	7	12
Total .. ..	50	114
	$\chi^2=1.005$ ; P: 0.8	

TABLE VI

Duration of Disease in 5-year Groups	Arrested or Quiescent Disease	
	Pregnant	Non-pregnant
0-4 .. ..	107	89
5-9 .. ..	46	26
10+ .. ..	13	10
Total .. ..	166	125
	$\chi^2=1.881$ ; P: 0.7 to 0.5	

The value of these figures is that they give a time picture of the state of the disease and a factual contrast to an opinion based on radiological appearances.

Details of the obstetric history were lacking in most cases, but no obstetric deaths were recorded. Two patients

were delivered by caesarean section on obstetric grounds; another who became ill showed multiple opacities in a x-ray film of the chest, diagnosed as metastatic pulmonary abscesses following puerperal cellulitis. This patient recovered after a long pyrexial illness.

#### Comments on Tables

Each of the foregoing tables has been submitted to the  $\chi^2$  test. The value of  $\chi^2$  and the limits of P (probability) are shown for each of the tables.

Where the value of P is greater than 0.05 the degree of difference between the two compared groups has been taken to be of no significance. In only one case—the age distribution of the arrested or quiescent cases—is the difference significant; in this respect, therefore, these two groups are not alike.

Table I shows that the proportion of pregnant women with active disease to those whose disease is quiescent is much lower than in the control series, where there is nearly the same number in each group. This suggests that women with active disease do tend to avoid child-bearing. Among those patients with active disease 11 (22%) were diagnosed during pregnancy; the other 78% became pregnant knowing they were ill and presumably against the advice of their physicians. At two of the clinics from which the control group was obtained it is known that 60 women had pregnancies in the period covered by the investigation (approximately 18 months). This gives an annual rate of pregnancy of one in 12 women of child-bearing age for this particular group of tuberculous women, which is almost the same as the estimated rate for the whole of Middlesex at about the same time. If we are correct in assuming that the woman with active pulmonary tuberculosis avoids pregnancy then it would appear that the rate of conception among those women whose disease has remained dormant for some time is similar to that of the normal population.

There is general agreement that 10% of marriages in this country and in America are naturally sterile (Hambley 1942; Report on Conference of the British Social Hygiene Council, 1943); such cases and those women who deliberately avoid pregnancy for one reason or another will appear in the control group. Pregnancy is also more likely to occur in younger women; this accounts (at least in part) for the greater proportion in the higher age group in the non-pregnant control series (see Table II, arrested or quiescent cases).

#### Assessment

The state of the disease was assessed at the beginning of pregnancy, or in the case of the controls as near to January 1944, as available records allowed, and was compared with the state 12 to 15 months later. Assessment was based upon clinical notes and radiological appearances in every case, and where available on examination of sputum, gastric contents, and laryngeal swabs for tuberculosis bacilli. In patients who were receiving treatment in hospital the detailed hospital reports, with temperature records, etc. were used. In the cases of non-active disease only relapses are recorded; no deaths occurred in this group. Patients classed as "better" in the group with active disease had become "quiescent"—that is, there had been general clinical improvement, sputum examinations were negative, and x-ray appearances were those of resolution and regression and no sign or symptom suggesting activity was present. Any case remaining active, even though there may have been improvement under one or more of the above observations, was classed as stationary. Relapsed cases showed clear evidence of clinical and radiological deterioration. S

s to obtain as uniform an assessment as possible throughout, all case papers and films were inspected by only one of us (C. J. S.).

### Results

The pregnant cases are separated into those that went to term and those in which the pregnancy was surgically terminated, including one case of abortion at the fourteenth week. The similarity of the outcome in the pregnant and the non-pregnant groups both for active and non-active disease is striking (Tables VII and VIII). Note the three

TABLE VII.—Results in Active Cases

Change in State of Disease	Active Disease		
	Pregnant		Non-pregnant
	Artificially Terminated	Full-time	
Better .. ..	7 (35%)	11 (36.6%)	42 (36.8%)
Satisfactory .. ..	5 (25%)	11 (36.6%)	35 (30.7%)
Worse .. ..	4 (20%)	4 (13.3%)	16 (14%)
Dead .. ..	4 (20%)	4 (13.3%)	21 (18%)
Total .. ..	20	30	114

TABLE VIII.—Results in Arrested and Quiescent Cases

Change in State of Disease	Arrested and Quiescent		
	Pregnant		Non-pregnant
	Artificially Terminated	Full-time	
Satisfactory or improved .. ..	33 (92%)	117 (90%)	110 (88%)
Worse .. ..	3 (8%)	13 (10%)	15 (12%)
Dead .. ..	0	0	0
Total .. ..	36	130	125

categories of the "active" patients: though the numbers are not large, we are of the opinion that these may be fairly compared, each containing similar proportions of patients with unstable or moderately active or severe progressive disease. Those patients whose pregnancy was terminated fared no better than those going to term or the control patients who had no pregnancies related to the period of observation.

The effect of the difference in the age distribution in the non-active cases is difficult to assess. Nevertheless it is felt that the figures for this group are worth presenting if they serve merely to demonstrate the difficulty in obtaining comparable unselected control groups. It might reasonably be expected that a higher relapse rate would have occurred among the relatively younger women who had borne children. For this reason the evidence is the more suggestive that pregnancy and parturition have little effect upon the course of stable or healed disease.

### Discussion

We feel that our investigation permits the broad deduction that, in general, a single pregnancy has little or no effect upon the course of a tuberculous illness whether the disease be active or non-active. Patients whose pregnancy is artificially terminated would seem to fare no better than their sisters who are allowed to continue to term. Thus it becomes incumbent upon those who advise termination of pregnancy as an almost routine procedure to establish its necessity in each patient rather than assume that it is of obvious and universal value.

These conclusions are supported by the more recent writers on the subject (Cohen, 1946; Ornstein and Epstein, 1939; Jameson, 1938; Mariette, Larson, and Litzenberg, 1942). Particularly in regard to the non-active cases they are agreed that there are no grounds connected with pulmonary tuberculous disease for advising termination. The few but well-documented and carefully reviewed cases of Cutler (1944) give further support to this view.

We wish to stress that in any investigation of this kind cases should be collected and reviewed over a limited number of years because of the variations in the standard of living and methods of treatment. Both are important factors influencing the outlook for the sufferer. These figures were collected during the latter part of the war, at which time the standard of nutrition in this country was fairly uniform and when the general management of patients and treatment by "collapse" therapy for cases in which it was indicated were reasonably consistent throughout the county of Middlesex.

### Conclusions

Pregnancy as an event in the course of a tuberculous illness has little or no effect upon the progress of pulmonary disease over a period of fifteen months whether the disease be active or quiescent; deterioration in the state of some tuberculous patients must be expected whether they are pregnant or not.

There is no evidence that surgical termination of pregnancy is necessary in the medical management of tuberculous pregnant women, except in a few selected cases. While it must be left to the physician in full possession of all the details of the individual case to make the proper decision with regard to the management of the patient, pessimism as to the influence which pregnancy has on tuberculosis and undue zeal in the termination of pregnancy are to be avoided.

### Summary

The change in the state of active pulmonary tuberculous disease has been assessed over a period of 12 to 15 months (period of child-bearing and early infant-rearing) in 50 pregnant women and 114 married women of child-bearing age who had had no pregnancy in relation to the period of assessment. The two groups were found not to be significantly different in any of the following respects: (a) age, (b) social class, (c) number of previous pregnancies, (d) duration of disease. At the end of the period of assessment in approximately 35% of all cases the disease was found to have become quiescent. Over the same period 30 to 40% in each group had deteriorated or died.

A group of 166 pregnant and 125 non-pregnant women whose tuberculous disease at the beginning of pregnancy was quiescent or arrested was similarly assessed. There was a significant difference in the age composition of these two groups. In each of these groups 8 to 12% deteriorated in a period of 15 months. There were no deaths in either group.

We would like to thank the physicians and their staffs of the clinics from which the records were obtained, particularly Dr. Norman MacDonald and Dr. Nicol Roe, from whose clinics the control group was obtained. To Dr. W. T. Russell and his assistant, Ian Sutherland, of the Institute of Social Medicine, Oxford, we are particularly grateful for much helpful advice on the statistical presentation of the results. We are solely responsible for all statements made and views expressed in this paper.

## APPENDICITIS IN THE YOUNG CHILD

BY

HOWARD WILLIAMS, M.D.

(From the Melbourne Children's Hospital)

While appendicitis below the age of 3 years is not uncommon it is so frequently overlooked in the early stages and so often complicated when diagnosed that I am placing on record the common clinical features and problems encountered in dealing with 42 children with appendicitis in this age group. The object of this paper is to help the family doctor to understand more clearly the clinical pattern and problems of appendicitis in the young child, to indicate how it differs from that in the older child and so enable him to establish a diagnosis before complications have developed. It is mainly by early diagnosis and prompt treatment that the mortality and morbidity will be lowered. The situation is that uncomplicated appendicitis can be successfully treated, but complicated appendicitis, especially if general peritonitis be present, is a very dangerous illness with a high mortality.

The incidence of the disease in young children is shown in our figures from the Children's Hospital, Melbourne: Between 1935 and 1940, 1,487 children under the age of 14 years were treated for acute appendicitis, of whom 42 were under the age of 3 years. One patient was under 1 year, 11 between 1 and 2 years, and 30 between 2 and 3 years of age.

## Pathological Features

In this group of 42 patients three main morbid anatomical states were found at operation.

1. *Acute Uncomplicated Appendicitis*.—In 6 patients the acutely inflamed appendix was lying free in the general peritoneal cavity. Although gangrene was present in several, the appendix was unruptured. In some a little clear or slightly turbid fluid was found in the peritoneal cavity.

2. *An Inflammatory Mass*.—In 21 patients an inflammatory mass was found. This mass was the result of a local peritonitis, the appendix being walled off from the general peritoneal cavity by fibrinous adhesions between intestinal loops and peritoneum. The appendix was usually gangrenous and perforated, and a small abscess was commonly present. The omentum by reason of its immature development at this age played a negligible part in localizing the spread of the inflammation.

3. *A General Peritonitis*.—In 15 patients a general peritonitis was present, the result of either (a) rupture of an obstructive type of appendicitis with dissemination of appendicular contents over the peritoneal cavity, or (b) extension from a local peritonitis with an abscess.

It is thus very evident that appendicitis in this young age group, unlike that in older children, is usually complicated by either a local or a general peritonitis. The two important factors accounting for this are the long time interval from the onset of symptoms to the diagnosis and the more rapid progression of the inflammatory process to gangrene and perforation. The small immature omentum also fails to assist in sealing off the appendix effectively from the general peritoneal cavity. While it is uncommon for acute appendicitis to become complicated in under 24 hours, the variability of the rate of progress of the inflammation in this young age group makes it difficult to predict in any one patient what precise morbid state will be present at any particular time. Three examples from this series illustrate this variability: one patient who had been ill for as long as 60 hours had an uncomplicated unruptured appendix; another patient who had been ill for only 24 hours had an inflammatory mass; while another who had been ill for a period as short as 4 hours had a general peritonitis, the result of rupture of an obstructive type of appendicitis.

## Clinical Features

*Bellyache and vomiting* are the predominant symptoms. The illness almost always begins in a child who has been quite well. Not infrequently the initial symptoms may be of a general nature—peevishness, irritability, feverishness, refusal of food, and vomiting. Usually within an hour or two the mother is made aware that the child has pain or discomfort in the belly. He may wince, whimper, or cry, and say that his "tummy is sore," or he may hold his hand to his belly. He will want to be comforted. Owing to their very limited powers of expression these young children are unable to give any accurate information as to the nature, quality, or situation of the pain. This is a matter of secondary importance, the significant fact being that the child shows by his behaviour that he has pain in his belly. No fewer than 36 of the 42 mothers were quite definite that their children had pain, discomfort, or soreness in the belly. In 21 of the 36 the pain appeared to come in definite spasms during which the child would whimper or cry. In 15 of the 36 the pain seemed to be of a more constant nature. It is important to appreciate that the pain may be quite mild. These children may be very bright and active in between the spasms of mild bellyache. We should not be lulled into a sense of false security in interpreting a mild pain as being of no importance.

Vomiting is an even more constant symptom than pain. 39 of the 42 patients vomited repeatedly. There are distinguishing features about the vomiting in appendicitis: it may precede or follow the onset of pain. Late in the illness with peritonitis the vomiting may be faeculent.

I cannot sufficiently stress the clinical significance of continued abdominal pain and vomiting in the young child. Appendicitis should at once be suggested as a probable cause.

*Bowel Function*.—Constipation is by no means the rule and in almost half of the patients the bowels acted normally. Of the patients 14 were constipated, while 9 had diarrhoea.

*Disturbance of Urination*.—In 3 children with peritonitis and local peritonitis the frequent and painful passage of urine was the outstanding feature of the illness and in one patient retention occurred. It is quite likely that the pain was lower abdominal and was simply associated with frequent micturition.

## Examination

In no other field of medicine is there greater need for patience and gentleness than in the examination of the young patients. Examination at the first attempt is often unsatisfactory owing to the child being fretful, irritable and resentful of being disturbed. To persist with an immediate examination is worse than useless, for reliable information will not be obtained and examination later may be made more difficult. Call again in half an hour or wait over a cup of tea, and by this time the child is often co-operative and examination easier. Should the child still be fretful and resentful the practitioner is wise to refer the patient to a hospital, where expert opinion can be obtained. The practitioner as a rule has not the necessary time to call at half-hourly or hourly intervals at a patient's home until satisfactory examination can be made. These patients cannot be safely left till the morning to see what develops. In hospital it may be necessary in a few cases to administer either a sedative or a light ether anaesthetic to obtain satisfactory examination of the abdomen.

While one is gaining the confidence of the child an assessment of the state of the general health and condition is made. Some of these patients have a characteristic attitude in that they lie still either on their back or with their legs

curled up. Often they resent being disturbed or asked to sit up, as active contraction of the abdominal wall is painful. In this they differ from children with acute infections such as tonsillitis or otitis media or gastro-enteritis, who are restless or change their posture frequently.

Abdominal examination is the most important and most difficult part of the procedure. The two chief abdominal signs of appendicitis are tenderness and rigidity, and they are rarely absent. Valuable evidence of rigidity is obtained from observation of restricted movement of part or whole of the abdomen. Palpation is best carried out with the warm hand pressing gently on the abdomen and quietly feeling with the finger-tips as the child breathes. Always begin palpation in the upper and left side of the abdomen in the area where you do not suspect tenderness, and gradually move to the suspected areas of tenderness—namely, the right lower quadrant of the abdomen, the suprapubic region, and the right flank. Tenderness is determined by observing whether the child winces or attempts to pull away the palpating hand when pressure is applied to a focal part. It is better not to ask a child of this age whether a particular area is or is not sore. The reply may be misleading. Objective evidence of tenderness is much more reliable than subjective evidence. The usual site of tenderness is in the right lower quadrant of the abdomen. Suprapubic tenderness, especially on the right side and when pressure is directed towards the pelvic cavity, is quite common owing to the frequency of pelvic appendicitis. With spread of the peritonitis the tenderness may extend over the entire abdomen. While tenderness is usually very definite in most patients it may be slight in others, especially in the patient with pelvic appendicitis. The degree of tenderness is not reliable in assessing the precise state of the inflammatory lesion inside the abdomen.

*Muscle-guarding* is best determined by comparison and by judging whether relaxation or guarding remains when the child is breathing quietly. Do not move the palpating hand rapidly from area to area comparing muscle tension, as one is likely to be deceived by voluntary guarding. The area of muscle on guard may be quite small. In pelvic appendicitis it is frequently in the lower portion of the right rectus muscle.

An abdominal mass occurred in half of these patients; it was commonly felt as a firm discrete non-mobile mass, but in a few patients as a diffuse thickening. The degree of tenderness and muscle-guarding over a mass is very variable; it may be minimal, in which case the mass is easily felt, or so acute that it is difficult or at times impossible to determine the presence or outline of the mass.

*Abdominal distension* is common when general peritonitis is present, and is often observed in pelvic appendicitis and peritonitis.

*Rectal examination* can be misleading, for no matter how quietly and gently performed it will cause some children so much discomfort that it is impossible to assess whether there is any tenderness in the pelvis. If the child cannot be coaxed to be quiet during the examination then it is useless and misleading to attempt to determine whether there is any tender area in the pelvis. Some children will be quiet and co-operative. Rectal examination, however, is an invaluable measure to determine the presence or absence of a pelvic mass.

After abdominal examination routine clinical examination is conducted, particular care being directed to the chest, ears, and throat. Too much attention is often given to alterations in the pulse rate and temperature in the diagnosis of appendicitis. Neither pulse nor temperature gives a reliable indication of the inflammatory state inside the abdomen. It is well to realize that a child may be dangerously

ill with a normal temperature or one of only 99° F. (37.2° C.), while a temperature of 103 or 104° F. (39.4 or 40° C.) by no means makes a diagnosis of appendicitis unlikely. A very rapid weak pulse is a good indication of the severity of either dehydration or toxæmia or both, and usually is found in patients with general peritonitis. In some patients with appendicitis the pulse rate is only very slightly increased.

### Diagnosis

In some cases diagnosis may be difficult owing to a considerable variation in the clinical pattern, but the following are the essential facts.

A history from the mother of continued bellyache or discomfort and repeated vomiting should be presumptive evidence of appendicitis. I am of the opinion that such a history places the responsibility on the medical attendant of suspecting appendicitis and of acting accordingly. Determination of either focal abdominal tenderness or rigidity, or both, leaves no doubt that the clinical diagnosis is acute appendicitis. If in addition to these signs a mass is present in the pelvis or lower half of the abdomen then one should be very confident of the diagnosis. Should abdominal tenderness and rigidity be minimal one may be hesitant about the diagnosis if experience is limited. It is at this stage that expert opinion should be sought, and the practitioner should not carry the responsibility by waiting for the signs to become more definite.

Two kinds of patient present a different clinical onset and pattern which may be misleading. The first is the patient who has predominantly urinary symptoms and is suspected of having pyelocystitis. Should microscopical examination of the urine reveal the presence of only a small number of pus cells it is most improbable that a pyelocystitis is the cause of the illness. Patients with pyelocystitis who have pain and frequency of micturition have urine which is almost without exception heavily laden with pus cells and bacilli. The second is the patient with diarrhoea and abdominal pain who is suspected of having gastro-enteritis. Diarrhoea often occurs in pelvic appendicitis. Diagnosis is very difficult in the early stages of the illness, for the abdominal physical signs are usually minimal or absent and rectal tenderness is difficult to assess. Should a pelvic mass be present diagnosis is at once established.

In hospital practice total and differential leucocyte counts are commonly carried out as a diagnostic measure. They are of very limited value owing to the wide variations of the readings from normal to a very high figure of over 30,000 with a polymorphonuclear response. A normal, low, or very high reading would not for a moment deter me from making a diagnosis of acute appendicitis and of acting accordingly. The only real value of a leucocyte count in this disease would seem to be that if an unusual reading is found then the clinical evidence should be reconsidered before arriving at a final decision.

### Treatment

The treatment of these 42 patients, although conducted by several surgeons, was carried out on a uniform plan. All underwent operation as early as possible, the one factor delaying surgical intervention being a seriously ill child with peritonitis. Resuscitation by means of warmth, rehydration by intravenous therapy, and alleviation of intestinal distension by continuous gastric suction drainage were instituted until improvement of the patient permitted surgery to be undertaken safely. The time taken for improvement was from 6 to 12 hours and occasionally longer. The principles guiding the operative procedure were a planned incision giving the best access to the appendix, which was removed with the minimal possible disturbance of the

general peritoneal cavity. All patients with a mass or peritonitis were drained so that a tract for any exudate would be left from the site of the inflammatory lesion to the exterior. In all 42 patients the appendix was removed at operation. Post-operative measures were directed towards obtaining rest for the patient, and rest in particular for the alimentary canal. Morphine was given liberally, and when necessary continuous gastric suction and intravenous therapy were employed. The semi-Fowler position was adopted for all patients. Sulphonamides were used either by mouth or intravenously in one-third of the cases.

### Results of Treatment

There were eight deaths among the 42 patients. Three occurred in 11 patients aged 1-2 years; the remaining five deaths were among the 30 patients aged 2-3 years. The most important factor in mortality was the presence of general peritonitis. No fewer than seven of the 15 patients with general peritonitis died. The remaining death in the series was that of a patient with a mass and an abscess who developed a general peritonitis after operation. The other important factor in relation to mortality was the length of time the child had been ill before admission to hospital. Seven of the eight children who died had been ill for longer than 48 hours, while the other child had been ill for 40 hours.

### Conclusions

It is readily evident that the two major problems in appendicitis in the young child are: (1) How can an early diagnosis be established and so avoid complicated appendicitis with the accompanying high mortality and morbidity? (2) What is the best treatment for a patient with a complicated appendicitis, especially if general peritonitis is present?

Early diagnosis, within 12 to 24 hours of the onset, will be established only by better clinical training of the student, the family physician, and the paediatrician. This is the task of the clinical schools and societies. The two chief reasons for delay in the diagnosis are, first, a failure to suspect appendicitis at this age, and, secondly, a failure to take enough care with the history and clinical examination. It is not sufficiently appreciated that a single clinical examination is often inadequate and that several may have to be made before the physical signs are accurately determined. Rarely, late diagnosis is due to parents bringing their children for examination at a late stage of the illness.

The management of the patient with a complicated appendicitis presents a problem regarding which there is often a difference of opinion. Two main questions require an answer: (a) Should surgery be undertaken as soon as the patient's condition will permit, the object being drainage of pus and removal of the highly septic appendix if possible? (b) Should the body and alimentary canal be put at rest to allow the healing processes either to localize or to resolve the inflammation, the appropriate surgical treatment then being carried out?

While the main purpose of this paper is to assist the practitioner in establishing a diagnosis early and thus prevent complicated appendicitis, many problems concerning the complicated disease require to be solved. I would suggest that the different paediatric schools study these problems involved in the treatment of the complicated disease. Active clinical investigation would be an important measure in clarifying the clinical features for the student, house-physician, general practitioner, and paediatrician, and thus facilitating early diagnosis.

I am indebted to Prof. J. C. Spence and Dr. Donald Court for reading this paper.

## ENDOCYME FOETUS IN A FIJI INFANT

BY

R. W. D. MAXWELL, M.B., Ch.B.  
Medical Officer, Colonial Medical Service, Fiji

It is felt that the following case is of sufficient rarity and interest to merit its being placed on record: I am not aware of a similar case of *foetus in foetu* having previously been reported from this Colony.

### Case History

On Aug. 20, 1940, a Fijian female infant was admitted to the Lautoka District Hospital, Fiji, having been brought from Tavua, one of a small group of islands off the west coast of Viti Levu. The infant's age was later checked by reference to the provincial register of native births, and it was shown to have been born on April 11, 1940. Its age, therefore, at the date of admission was a few days over 4 months.

The mother being uneducated and rather unintelligent, an accurate history was difficult to obtain. She stated that the infant was the result of her first and only pregnancy. Nothing untoward had occurred during the pregnancy and she had remained well throughout. Labour had been quite normal, the mother being unattended until after delivery of the infant, when a native nurse had arrived in time to divide the cord and conduct the third stage. The infant had appeared perfectly normal at birth and nothing unusual was noticed until it was about three months old. The abdomen then began to enlarge, and continued to do so during the next month up to the time of admission to hospital. Over the same period the infant's general health had shown some impairment and its limbs had become thinner.

Both parents of the infant were of pure Fijian descent. There was no history of multiple births or of any congenital abnormalities on the mother's side. As the parents were unmarried and the father did not appear, his family history could not be obtained. The mother's age was about 26 years.

Examination of the infant showed it to be rather small for its age and poorly nourished, but there was no marked wasting. The abdomen was greatly enlarged, especially above the umbilicus, the enlargement appearing diffuse and symmetrical. On palpation the upper two-thirds of the abdomen was felt to be occupied by a large firm mass, irregular in outline and movable only within a narrow range.

On Aug. 22, under general anaesthesia, the abdomen was opened by a median supra-umbilical incision. The abdominal wall was greatly thinned from overstretching. The lower border of the stomach was seen crossing the upper angle of the abdominal opening, and below this the great omentum was spread out over a large smoothly rounded mass. An opening was then made through the omentum, revealing a smooth, grey solid mass enclosed in a very thin-walled sac. On incising the sac and passing a hand inside it the nature of the mass was finally revealed and a readily recognizable "foetus" was felt. The smooth-walled interior of the sac in which it lay contained a scanty amount of thin clear fluid. Owing to the large relative size of the foetus, the original abdominal incision had to be extended below the umbilicus before it could be delivered through the wound, and delivery was further facilitated by making one or two small incisions in the "head" of the foetus, from which some straw-coloured fluid escaped, thus reducing its size. Owing to the infant's weakly condition and the degree of shock produced by the delivery of the large intra-abdominal mass the operation had to be concluded without delay, and it was not possible to make any detailed exploration of the relations of the sac. It occupied the upper abdomen, lying between coils of small intestine, and was attached to the posterior abdominal wall. No attachments of the foetus to the interior of the sac had been felt. No attempt was made to remove or otherwise deal with the sac. It was left open, replaced in the abdomen, and the abdominal wound was sutured.

The weight of the foetus after removal was 1 lb. 10 oz. (737 g.), and the infant's weight on the day after operation 8 lb. 4 oz.

(3.74 kg.). On Aug. 25 a partial resuture of the abdomen was required, but otherwise the patient made an excellent recovery, and was discharged on Oct. 24, 1940. Her weight was then 11 lb. 4 oz. (5.12 kg.).

### The Foetus

This is illustrated in the accompanying photograph. There was a globular cephalic portion constituting rather more than half the total bulk of the foetus. Inside this cephalic portion were a number of fluid-containing cavities, covered in the greater part by skin only. There were two clearly recognizable upper limbs. The right upper limb showed flexures in the

position of elbow and wrist and had four distinct digits with well-defined nails. The left upper limb showed a distinct elbow and wrist, but the hand was less well developed, consisting of a mass in which five partly fused digits appeared to be represented, with a sixth, apparently supernumerary, digit at some distance from the rest. The nails were distinctly seen. There was a wedge-shaped caudal mass with a small terminal appendage arising from the bottom of a small pit-like depression. There was a short slender stump of "umbilical

cord," about 1 in. (2.5 cm.) long, attached to the ventral surface between the upper limb processes. This was not felt before delivering the foetus, but appeared to have been ruptured in doing so. It was apparently the only slender communicating link between parasite and autosite, and, since the foetus at operation had presented by the dorsal surface, it had presumably been attached to the posterior abdominal wall of the infant. The whole foetus was of a pinkish-grey colour and was covered in parts with a thin layer of sebaceous matter exactly resembling vernix caseosa. There was patchy lanugo over the dorsal aspect and the limbs, and a patch of well-developed hair on the anterior aspect of the "head." The length of the foetus was 6 in. (15 cm.) and its weight, as stated, 1 lb. 10 oz. The foetus was therefore approximately one-fifth the weight of the infant at the time of removal, and there was no doubt that it was then still "alive" in the sense that it was continuing to grow.

A skiagram of the foetus was taken after removal. Unfortunately, since a diagnosis was not made before operation, it was not x-rayed *in situ*. A rudimentary spine could be seen and also the long bones in the upper limbs. In the left upper limb the humerus, radius, and ulna were well developed. The wedge-shaped caudal portion of the foetus showed a single long bone, presumably a femur, and apparently represented a rudimentary lower limb.

I have to thank Dr. H. Silvester Evans, Acting Director of Medical Services, Fiji, for permission to publish the case.

Gould, George M., and Pyle, Walter L. (1897). *Anomalies and Curiosities of Medicine*, p. 199. London.

The latter work contains a number of other references to literature on this subject.

The Minister of Health has adopted the following recommendations of the Nurses Salaries Committee concerning the salaries of nurses employed in part-time service. If employed for not more than 30 hours a week: female ward sister, 2s. 11d.; female staff nurse (general trained), 2s. 3d.; female enrolled assistant nurse, 2s. If regularly employed for not more than 30 hours a week, but required on occasion to work for a few hours more, a nurse should be paid for the first 30 hours at the rates listed above and for additional hours as follows: female ward sister, 2s. 7d.; female staff nurse (general trained), 2s.; female enrolled assistant nurse, 1s. 10d. Nurses who regularly work more than 30 hours a week should be paid on the non-resident salary scale for the grade, provided that no nurse employed for more than 30 hours a week receives less than a member of her grade employed for only 30 hours.

## Medical Memoranda

### Severe Anaemia due to Diaphragmatic Hernia

It does not appear to be widely recognized that herniation of the stomach through the oesophageal hiatus of the diaphragm, often with minimal gastro-intestinal symptoms, may be associated with severe anaemia.

Hiatus hernia with ulceration was described by Richard Bright in 1836, but it was considered an uncommon condition until recent years, when improvements in radiological technique have made it clear that it is not infrequently the cause of upper abdominal symptoms. Radiological examination should include examination of the stomach in the supine, prone, and Trendelenburg positions in addition to the erect.

That hiatus hernia is capable of causing bleeding was emphasized by two American workers in 1943. Murphy and Hay (1943), examining the findings in 72 patients with hiatus hernia, of whom 84% were females, found the average age to be 60 years; pain was a prominent feature and anaemia was almost as frequent, for 27% of patients had a marked microcytic anaemia. Sahler and Hampton (1943) found either anaemia or a history of gastro-intestinal haemorrhage in 14.5% of a series of 221 patients with hiatus hernia. Chevallier and Danel (1944) and Mendelsohn (1946) reported cases of hiatus hernia with severe anaemia, the latter finding hiatus hernia in 16 out of 1,000 consecutive gastro-intestinal radiographs, three of which patients had bleeding as a symptom.

Gastroscopic and post-mortem examinations in cases of hiatus hernia with anaemia (Sahler and Hampton, 1943) have indicated the cause of the bleeding to be the constricting effect of the diaphragm on the herniated stomach, so that venous engorgement and oedema, with submucosal haemorrhages and shallow ulcerations, occur. Peptic ulcer of the lower oesophagus is a rare cause (Bock, Dulin, and Brooke, 1933).

### CASE REPORT

A married woman aged 64, with two children, had always enjoyed good health and had run a small shop unaided. For two weeks before admission to hospital she had been feeling increasingly weak and tired, was dyspnoeic on little effort, and had noticed swelling of the ankles. Appetite and bowel habit were unchanged, no darkening of the stools had been apparent, and she had not lost weight. On direct questioning the only other symptom to which she would admit was a feeling of fullness behind the mid-sternum. This was not troublesome and was attributed by the patient to having her meals disturbed by attending to customers in her shop. This symptom had been present for six months.

On examination the patient was seen to be somewhat obese, with marked pallor of skin and mucous membranes, ankle oedema, and dyspnoea on slight effort. There were no other abnormal physical findings. A blood count showed: haemoglobin (Haldane), 30%; red cells, 2,424,000, moderate anisocytosis and poikilocytosis; colour index, 0.63; white cells, 6,800. Examination of the sternal marrow revealed erythropoiesis, normoblastic in type and active. The faeces contained no macroscopic blood, but occult blood was present. Fractional gastric analysis revealed normal acidity. Gastric radiographs taken in the supine position showed the oesophagus entering the stomach in the abdomen, and a large part of the stomach herniated through the oesophageal hiatus into the thorax. The hernia was not visible in the erect position. Ulceration was not seen in oesophagus, stomach, or duodenum. A barium enema showed no colonic abnormality. Chest radiographs revealed no abnormality. The patient responded very rapidly to blood transfusion (2 pints (1.14 litres) of concentrated cells) and intensive iron therapy. Two weeks after admission the haemoglobin was 72% and red cells numbered 4,660,000. One must conclude that in any case of unexplained microcytic anaemia full consideration should be given to the possibility of hiatus hernia.

Our thanks are due to Dr. S. Almond for helpful criticism and for permission to publish this case, to Dr. Goldman for examination of the sternal marrow, and to Dr. Morris and Miss Lowe for radiological examinations.

## Reviews

### VESALIUS

*A Prelude to Modern Science. Being a discussion of the History, Sources and Circumstances of the "Tabulae Anatomicae Sex" of Vesalius.* By Charles Singer and C. Rabin. Publications of the Wellcome Historical Medical Museum. New Series, No. 1. (Pp. 141; 59 text-figures, and 6 plates. 50s.) London: Published for the Wellcome Historical Medical Museum at the Cambridge University Press. 1946.

The history of medicine and the allied biological sciences has in the past owed much to many learned members of the medical profession in this country. Indeed, until comparatively modern times biology had no existence apart from medicine. This leaning towards the historical approach to learning is foreshadowed in the works of Thomas Linacre and John Caius, and acquires a more definite form in the *History* of John Freind. Thereafter, to mention only some representative names, the lead was followed by Thomas Young, Francis Adams, William Greenhill, William Ogle, and Frank Payne. Dr. Singer's studies, therefore, are in line with an expanding and distinguished tradition, and his own work is a record of masterly additions to the *opera magna* of his predecessors. So far his research has inclined rather towards the general and philosophical aspects of history, but in the monograph now reviewed he has shown that he can work also in miniature and without loss of that scrupulous accuracy so dear to the meticulous historian. His colleague, Dr. C. Rabin, has made available such knowledge of comparative philology as was essential to the development and completion of the argument.

This prelude to modern science takes the *Tabulae Sex* of Vesalius as a text on which to base an investigation not only into the sources of the *Tabulae* but also into the "currents of thought that lie behind it, and its relation to contemporary studies and activities, medical, intellectual and artistic." Such a research makes exacting demands on the judgment and scholarship of the authors, and that these demands have been met there can be no question. Dr. Singer thus celebrates his seventieth birthday by the publication of a work which will ensure for him in times to come a place among the elect of the historians of science. The plan of the work includes a historical analysis of anatomical and medical terms of the Renaissance, the character and purpose of the *Tabulae Sex* of 1538, Galenic physiology and its Latin presentation, Vesalius's reliance on and use of animal *vice* human anatomy, and a photographic reproduction of the *Tabulae* with English translation and an elaborate critical commentary. As only two complete sets of the *Tabulae* have survived, and only one of the three facsimile editions is readily available, it is gratifying that all students of the history of anatomy may now obtain a copy of the *Tabulae* which for purposes of research is an adequate substitute for the original. The Wellcome Historical Medical Museum and the editor of the series, Dr. E. Ashworth Underwood, are to be congratulated on the publication of this very important work.

F. J. COLE.

### MYO-FASCIAL INFLAMMATION

*Rheumatism and Soft Tissue Injuries.* By James Cyriax, M.D. (Pp. 410. 42s.) London: Hamish Hamilton Medical Books.

This well-produced book is mainly an expansion of the author's views on physical medicine, most of which have been previously published elsewhere, and he discusses rheumatism less than might be supposed from the title. In the chapter entitled "Traumatic and Rheumatic Inflammation" he puts forward the hypothesis that both terms designate an identical type of inflammatory lesion arising in the myo-fascial tissues without apparent cause, and resolving with irregular fibrous scarring and the formation of organic adhesions. It is on the basis of this simple pathology that he has founded his method of treatment by mobilization of the soft tissues. He is somewhat dogmatic throughout the book, as, for instance, in his saying that nodules have no importance in the chronic rheumatic diseases, or, again, in such a statement as "Lumbago . . . is now known to have no connexion with rheumatism, being in

fact the name given to an attack of internal derangement in lower lumbar-spinal joint." In spite of this remark (in Chap. 11) he discusses the therapy of lumbar fibromyositis at so length on the assumption that a muscular lesion is responsible. He criticizes the current terminology of rheumatic diseases rightly pointing out that much of it is unnecessary and should be simplified. He states, for example, that osteo-arthritis is no connexion with rheumatism and omits it from his classification, but later he classifies bursitis of the shoulder under fewer than five headings. In the next chapter he summarizes current views on referred pain, and then in an interesting section considers the diagnosis of soft-tissue lesions, which he refers to as the clinical aspect of the work of a physiotherapist department, stating that "the problem which faces the physiotherapist is 'Where is it?' rather than 'What is it?'" In this chapter he tries to describe the principles of a systematic diagnosis which will reveal the origin of a pain wherever the symptoms are perceived, and he discusses the use of local analgesia for this purpose. In the next twelve chapters he relates this system to pains of all sorts as they affect the various regions of the body and includes notes on treatment.

Chapters 17 and 18 on "Treatment by Movement" are perhaps the most important ones in the book, for he there describes his whole theory and practice of deep massage. They follow a section on anaesthesia and analgesia, and one on functional pain in which he reveals considerable experience and wise handling of the psychoneurotic patient. He then considers the problem of rheumatism and non-specific arthritis, but he little new to say upon the subject if we accept his encouraging statement that "fibrositis and fibromyositis are conditions very simple to relieve if the medical man finds the site of scar tissue and the physiotherapist has learnt how to deal adequately with such adhesions." The view expressed that "it is in the highest degree sanguine to trust that vaccine therapy will modify the course of fibrositis" is reinforced by a later statement: "I worked for over a year at a clinic at which vaccines were injected with the intention of benefiting patients with the rheumatoid arthritis, osteo-arthritis, prolapsed intervertebral disc, spondylitis deformans, and fibrositis alike, and my experience there confirmed me in this view." Under the heading of "Infective Arthritides" he discusses rheumatoid arthritis, infective arthritis, and "spondylitis deformans," but he has compressed his account of the treatment of rheumatoid arthritis into little more than a page. In the final "Commentary" he suggests a working hypothesis that our knowledge of all the rheumatic diseases, from rheumatic fever and chorea to epidemic torticollis, can be unified on the basis that they show evidence of virus aetiology, and he makes a plea for further research along these lines.

The volume is lavishly illustrated with photographs, some of which are perhaps redundant, and line drawings by Mr. Michael Rotherstein. Some medical men and physiotherapists will read it with interest, but it is perhaps rather too long and too specialized to become widely popular.

W. S. C. COPEMAN.

### CHILDREN'S DISEASES

*Diagnostik der Kinderkrankheiten.* By E. Feer. Fifth revised edition. (Pp. 428; 285 illustrations. 32s.) Vienna: Springer-Verlag. London: H. K. Lewis and Co.

It is good to see a new edition of Prof. E. Feer's book, for it is an old and trusty friend to many paediatricians. This new version (the fifth edition) is published from the Springer firm in Vienna, whereas the book previously appeared as a special part of a larger work—the *Enzyklopaedie der klinische Medizin*—and bore the imprint of Julius Springer, of Berlin. These facts are mentioned as an indication of the revival of medical book publishing in German-speaking parts of Europe.

Prof. Feer has extensively revised the book and included some new illustrations, though many old friends remain. The x-ray photographs of lung conditions are clearer, but in contrast the few on heart disease are disappointing. The younger children are illustrated—and Switzerland presumably has a good supply—have less umbilical protrusion than is usual in Britain. (We refer to the illustrations before the text because they are such a dominant feature of the book.) Prof. Feer has added a summarized account of metabolism, the endocrine glands, and the

vitamins, but it is not full enough to help much in diagnosis. On the other hand he has extended the scope of the book, and thereby improved it, by discussing some aspects of treatment where they have a bearing on diagnosis.

Originally dedicated to his wife, Prof. Feer's book now is presented to his four children and twelve grandchildren. He can be assured that its popularity and value have grown over the past quarter of a century as certainly as his family.

ALAN MONCRIEFF.

### EASY CHILDBIRTH

*The Birth of a Child. Obstetric Procedure in Normal Childbirth for Those who Attend Women in Labour.* By Grantly Dick Read, M.D. (Pp. 99. 5s.) London: William Heinemann Medical Books. 1947.

Dr. Dick Read's views on normal childbirth and its management, from the standpoint of rendering it easy and less painful, are sufficiently well known not to require any introduction. In this small and inexpensive book he restates his beliefs in a simple and practical form suitable for midwives, physiotherapists, and the laity, as well as doctors. It should be a particularly useful book for intelligent expectant mothers (and fathers) to read for themselves. Essentially it is a collection of lectures and previously published papers, and most of the chapters are complete in themselves, each a variation on the same theme. Inevitably, therefore, there is much repetition, which may be instructive to the lay reader even though wearisome for others.

Few will question the fundamental soundness of Dick Read's ideas, though some may think he overstates his case. It is to be hoped that this book will not lead readers to expect too much so far as painless labour is concerned, and that it will not be allowed to discredit what is perhaps the most important aspect of his thesis—namely, that emotion and nervous tension can, and often do, profoundly disturb and inhibit uterine action in labour.

T. N. A. JEFFCOATE.

### BEDSIDE VERSES

*The Diagnosis of the Acute Abdomen in Rhyme.* By Zeta. Drawings by Peter Collingwood. (Pp. 88; illustrated. 5s. 6d.) London: H. K. Lewis and Co. 1947.

How much surgery should be taught the medical student of the future? Most of the operations that he now watches with interest but without profit, particularly the major operations of neurosurgery, cardiovascular, thoracic, and gastric surgery, proctology, and urology, should be shown rather to post-graduates. But all medical men should be taught the principles of first aid, the treatment of soft-tissue injuries and ambulant cases of fracture, the surgery of sepsis and in particular of the septic hand, the part that operative surgery can play in the treatment of disease (without operative details being discussed), and above all the recognition of all those emergencies in which early operation offers the only chance of saving life. Of these the abdominal emergencies are the most important.

*The Diagnosis of the Acute Abdomen in Rhyme* is an excellent little book, for "Zeta" considers the whole of this important subject with admirable completeness. Many of the more popular works favoured by the student tend to encourage the "penny in the slot" mentality: consult a table, stick in a few needles, send a few fluids to the laboratory, and the place where the pointer stops is the disease from which the patient is suffering. "Zeta's" advice is commendably practical. He insists that nothing can replace careful clinical observation, and that only by repeated bedside study can wisdom finally be attained.

The use of rhyme, the serio-humorous style, and the delightful cartoons by Peter Collingwood are exactly right, for lessons conveyed in this way remain in the mind long after these delivered in more serious vein have faded. The coat of arms on p. 21, with the motto *Per Annum ad Salutem*, might well be hung in every students' club. "Zeta" exemplifies many of his more important lessons by describing mistakes that have occurred in his own practice. This may be the reason why he has adopted a pseudonym, which masks without concealing the identity of one of the leaders of surgery to-day.

HENRAGE OGILVIE.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Ulcers of the Stomach and Duodenum.* By Edmundo Vasconcelos, M.D., F.A.C.S. (Pp. 125. No price.) Sao Paulo, Brazil: Editora Renascença S.A. 1947.

The author summarizes his experience of over 1,000 operations for peptic ulcer.

*Sex Power in Marriage.* By E. W. Hirsch, B.S., M.D. (Pp. 218 S3.) Chicago: Research Publications of Chicago. 1947.

A practical discourse on sex for the layman.

*Albert Schweitzer: The Man and His Mind.* By George Seaver. (Pp. 346. 18s.) London: Adam and Charles Black. 1947.

A biography of Schweitzer—theologian, philosopher, musician, and medical practitioner.

*Sex and Common Sense.* By Maude Royde, D.D., C.H. Revised edition. (Pp. 112. 8s. 6d.) London: Hurst and Blackett. 1947.

Essays on various aspects of sex and society.

*A Penicilina Por Via Arterial Nas Osteomielites.* By Eurico Branco Ribeiro. (Pp. 124. No price.) Sao Paulo, Brazil: Sao Paulo Editora S.A. 1947.

A monograph on penicillin in the treatment of osteomyelitis.

*Beiträge zur Kenntnis der Blutgerinnung.* By W. K. Rieben. (Pp. 96. 9 Swiss francs.) Basle: Benno Schwabe and Co. 1947.

A monograph on blood coagulation and anticoagulants.

*Brochure on Control of Malaria in India.* By C. F. Chenoy, M.B., B.S.(Bombay), D.T.M., D.P.H.(London.). (Pp. 63. No price.)

A short account of the malaria parasite, the mosquitoes that transmit it, and the control of the disease in India.

*Le Infiltrazioni del Simpatico.* By E. Tosatti. 2nd ed. (Pp. 203 No price.) Rome: Edizioni Italiane. 1947.

A monograph on infiltrating the sympathetic nervous system with local analgesics.

*New Biology.* Edited by M. L. Johnson and Michael Abercrombie. (Pp. 175. 1s.) London: Penguin Books. 1947.

A number of biological topics discussed for the layman.

*Introducción al Estudio de la Plasmoterapia.* By J. M. Massons. (Pp. 276. No price.) Barcelona: Editorial "Miguel Server." 1947.

A monograph on transfusion therapy, its technique, indications, and dangers.

*Rezeptaschenbuch.* Edited by L. Heilmeyer. 7th revised edition. (Pp. 410. No price.) Jena: Gustav Fischer. 1946.

A manual of classified therapeutics.

*Symptoms and Signs in Clinical Medicine.* By E. Noble Chamberlain, M.D., M.Sc., F.R.C.P. 4th ed. (Pp. 463. 30s.) Bristol: John Wright and Sons, Ltd. London: Simpkin Marshall (1941), Ltd. 1947.

A general account of how to examine the patient; the text has been thoroughly revised for this edition.

*The Trend of National Intelligence.* By Godfrey Thomson, D.C.L., Ph.D., D.Sc. (Pp. 35. 2s.) The Eugenics Society and Hamish Hamilton. 1947.

The 1946 Galton Lecture. The author suggests that the mean level of national intelligence is likely to decline.

*Cancer: Diagnosis, Treatment, and Prognosis.* By L. V. Ackerman, M.D., and J. A. del Regato, M.D. (Pp. 1,115. £5.) London: Henry Kimpton. 1947.

A general account of malignant neoplasms; with many illustrations.

*Nora e Rapida Interpretação do Quadro Leucocitário.* By Eurico Salis. (Pp. 26. No price.) Bagé: Rio Grande do Sul. 1947.

Notes on the differential leucocyte count.

SATURDAY NOVEMBER 8 1947

## THE END OF THE POOR LAW

"The Laws relating to the Poor," as they used to be called, have been an unconscionable time dying. There was the massive report of a Select Committee of the House of Lords in 1888. There were later reports by other committees, until in 1909 a Royal Commission unanimously recommended "a clean sweep" of the English Poor Law and Poor Law organization. Yet the death knell of the Poor Law was sounded only in 1929 when Parliament passed the Local Government Act, which extinguished the old boards of guardians and transferred their duties to local authorities. Even then in certain shapes and under an alias the Poor Law lingered. Lord Beveridge in his famous report five years ago recommended the transference to the State of the remaining public assistance functions of local authorities other than treatment and services of an institutional character, and he added, "In view of the increasing number of old persons there is probably considerable scope for experimentation with and development of services concerned with the recreation and welfare of the old, including special housing facilities." The National Assistance Bill, published last week together with a White Paper,<sup>1</sup> gives liberal effect to this social conception. It is described as a Bill to "terminate the existing Poor Law and . . . to make further provision for the welfare of disabled, sick, aged and other persons. . . ." The Bill is sponsored by the Ministries of Health and National Insurance and the Department of Health for Scotland. It consists of 65 clauses and 7 schedules, and it repeals in whole or in part something like 80 Acts going back as far as George I.

The proposals in this Bill complete the pentagonal structure of social security which the Government is erecting, the other four sides being the Family Allowances Act, the Industrial Injuries Act, the National Insurance Act, and the National Health Service Acts for England and Wales and for Scotland. It provides a comprehensive assistance service falling into two categories. The first takes the form of financial aid, which henceforth will be a national and not a local charge. The National Assistance Board, with advisory committees throughout Great Britain, will give a unified State service of financial assistance available according to need. This will take the place of unemployment assistance, supplementary pensions, blind domiciliary assistance, tuberculosis treatment allowances, and outdoor relief. It is expected that the applicants will be mainly the aged, disabled, and sick who are living in their own homes. The second category is the provision of residential accommodation for the aged and infirm and others, together with special welfare services for certain physically

handicapped persons. Here local authorities will continue to function, but the provision will be separated entirely from the relief of destitution; in other words, if an elderly person, irrespective of his means, is in need of care an attention he may become a resident in such a home, and his admission will have no more to do with what has been known as "relief" than the sending of a case of major illness to hospital. Those who receive such aid will not include the sick who need hospital treatment; they will be the responsibility of the National Health Service, to which it is estimated 50,000 people at present in public assistance institutions and 18,000 mental cases will be transferred. This new provision is for those whose disabilities prevent them from living a normal life at home. The majority of such people—the great majority as time goes on—will be in receipt of retirement pensions or insurance benefits, and, to save their pride as well as to relieve expenditure, they will be required to pay a fixed sum for their accommodation, leaving them with "pocket money." During the next five years it will be necessary to provide for this purpose 20,000 additional beds in England and Wales and 3,000 in Scotland, 60% of them in new buildings. It follows from the provision of such homes (hostels) by county and county borough councils that existing private homes which are run solely or mainly for old people or for the blind or those otherwise incapacitated will be subject to registration and inspection, but this will not apply to ordinary hospitals and mental institutions, registered nursing homes, and certain other exempt establishments. It is in keeping with the spirit of the Bill that voluntary organizations, whether for accommodation or welfare services, will not be discouraged, and indeed grants may be made to them.

In this proposed legislation the effect of the recent awakening of public interest in the care of the aged, as shown by the Nuffield inquiry and by the report of the special committee of the British Medical Association,<sup>2</sup> can be traced, but very little information is to be gathered from the Bill as to the proposed size or arrangement of such hostels. The B.M.A. committee suggested that they should be as near as possible to families and friends of the residents, and that, to prevent institutionalism creeping back, the number of residents in a home should be limited to 30 or 40. The amenities, of course, will depend less upon enactment or regulation than upon the way in which local authorities and their officers interpret their duties. We may have got away from the old idea of parish relief, the parish having been the immemorial "unit of obligation," but we still depend upon the public spirit of the locality. One clause in the Bill requires the local authorities to have regard to the need "for providing accommodation of different descriptions suited to the different descriptions of such persons." One may hope that the tautology of the Act will be translated concisely into a flexible administration. It is disappointing that the Bill does not go on to provide a co-ordinated medical service for these aged persons. All that is stated is that the medical service provided at the home or hostel will be of the kind specified in Part III of the National Health Service Act—that is, the service provided by local authorities

<sup>1</sup> Cmd. 7248. H.M.S.O., 3d. net.<sup>2</sup> Supplement June 21, p. 133.

including health centres, health visitors, and home nursing. The B.M.A. committee called for the establishment in each region of geriatric departments based on general hospitals. The medical service it suggested would have three interdependent units: the residential home for elderly persons in need of reception but not of nursing care, the long-stay annex for elderly patients whose cases were irremediable, and the geriatric department. The Government proposals will make it easier, however, for Regional Hospital Boards to institute some such arrangement.

Local authorities already have the duty of making arrangements for the welfare of the blind, and they are now to be empowered or directed to make similar arrangements for the deaf, the dumb, and others handicapped by illness, injury, or congenital deformity, instructing them in suitable cases in methods of overcoming their disability and training them for an occupation. One other provision should be noted. On the certificate of the medical officer of health persons suffering from grave chronic illness or the aged and infirm, living under insanitary conditions and unable to provide for themselves, may be removed to a suitable hospital.

The Poor Law, which stretches back beyond the Tudors, is at last broken. Its days began to be numbered when there appeared on the scene public health services, compulsory insurance, and State schemes of pensions for the aged and relief for the unemployed. A salute in passing should be given to the memory of Sidney Webb. He and Beatrice Webb<sup>3</sup> showed how the Poor Law would become of less and less importance in a social policy based on the duty of the State not merely to relieve but to eradicate the condition of destitution. The new Bill will mean another redistribution of income within the community. It will make more out of date than ever Disraeli's remark about the "two nations"—the rich and the poor—under the British sovereign. But the measure is well timed to the awakening of the public conscience regarding the aged and infirm, and interpreted with imagination in the spirit of social service it will give what the popular edition of the B.M.A. committee's report calls "A New Deal for the Old," to whom may be added the chronic sick and the physically handicapped.

### GAMMA GLOBULIN IN MEASLES

During the war solutions of human serum albumin were extensively used by the medical departments of the Defence Services of the United States for the transfusion of casualties. The system of fractionation developed by E. J. Cohn and his colleagues at Harvard aimed primarily at the preparation of pure human serum albumin for transfusion. As the work progressed a secondary objective developed, to separate the plasma proteins into a limited number of main fractions. The production of these solutions provides large quantities of the globulins from human serum as a by-product. It is known that the different antibodies in adult human serum are associated with the globulin fraction; accordingly, after methods for the preparation of the albumin solutions had been

perfected, attention was directed to the other proteins of human serum. As a result of a series of masterly researches at Harvard methods have been devised for the preparation of the different proteins of human serum in a high state of purity, and their chemical and physical properties have been fully investigated. At the same time workers in the immunological field examined the solutions of these different globulins for the presence of antibodies, determined the quantities present where this was practicable, and assessed their value as therapeutic agents.

Cohn and others<sup>1</sup> showed that the gamma globulins of the plasma proteins retained the physiological properties of antibodies after separation and that these globulins, from a purely physical standpoint, are the most active constituents of the plasma protein complex. Enders advanced the work a stage further when he succeeded in isolating a number of antibodies from the gamma globulin fraction. Sweet and Hickman<sup>2</sup> administered gamma globulin to some 267 susceptible children within eight days of exposure to measles. In assessing the results certain variables had to be considered, such as the nature of the contact and the varying potency of the gamma globulins used, though if the material is obtained from a large pool of human convalescent serum the potency of the antibodies may be assumed to be reasonably uniform; and, of course, in an investigation of this kind age and individual susceptibility play a part.

For children of 5 years or under 0.5 ml. seems to be an attenuating dose and about 2 ml. to afford protection. For older children up to the age of 12 approximately double the dosage is recommended. In the group of cases quoted by these authors about 50 developed mild measles and 7 had an ordinary attack. In 16 children who were re-exposed within four weeks of the original injection the protection appeared to be adequate; only three developed very mild measles.

A further paper by Sweet and others<sup>3</sup> describes the use of gamma globulin in an attempt to prevent infection in prematurely born infants. This failed, for after giving 2.5 ml. of this protein fraction to premature babies no improvement in the mortality rate was found. It would seem to be impossible to increase resistance to infection by giving gamma globulin in the absence of a fully developed reticulo-endothelial system and of the undifferentiated antibodies it produces.

The full harvest of these studies in immunology and therapeutics has yet to be reaped, but one result of great practical importance is the clear demonstration that the measles antibody is associated with the fraction of the serum proteins known as gamma globulin, that this fraction can be separated from the other proteins of serum and prepared in a high state of purity, and that its efficacy for the prophylaxis of measles is undoubted. This research aroused interest in many countries, and quantities of gamma globulin, small in amount but adequate for the purpose, were placed at the disposal of workers in Great Britain by the American authorities. The results reported from the United States were confirmed in this country.

<sup>3</sup> Webb, S., and B., *The Break-Up of the Poor Law*. 1909. London: Longmans, Green & Co.

<sup>1</sup> *J. clin. Invest.*, 1944, 23, 417. See *British Medical Journal*, 1945, 1, 739.

<sup>2</sup> *J. Pediatr.*, 1946, 28, 566.

<sup>3</sup> *Ibid.*, 1946, 28, 571.

Before the war the hospital and laboratory services of the London County Council had evolved a scheme which had shown the possibilities of a "convalescent measles serum bank." During the war limited quantities of adult human serum were supplied for the same purpose through the Public Health Laboratory Service. These forms of human serum differ in so far as the concentration of measles antibody is considerably greater in convalescent serum than it is in the serum of adults, yet neither is entirely satisfactory. While the dose of convalescent serum injected is small, the total quantity available in any year is limited, uncertain, and variable; on the other hand, though larger quantities of adult human serum could be obtained, and with greater certainty and regularity, the volume to be injected is inconveniently large except, perhaps, for very small children. Accordingly, comparative tests of the therapeutic value of gamma globulin and convalescent measles serum were carried out in order that information would be available to assist the authorities in their decision as to the form of measles prophylactic to be manufactured for use in this country. Some novel and difficult administrative and production problems arose. Whatever form of measles prophylactic was preferred, the raw material would have to be obtained from human beings; and while there had been no difficulty about supplies during the war it might not be so easy to obtain them in times of peace. The question of cost arose and could not be disregarded. By Cohn's methods gamma globulin is obtained when the concentration of electrolytes and ethyl alcohol, and the reaction, are suitably adjusted and sufficiently low temperatures are maintained throughout the operations; but these procedures tend to be costly. Again, Cohn's method yields a product of high purity and potency, but the amount of adult serum required to produce one dose of gamma globulin is relatively large.

These problems have engaged the close attention of administrative and research workers in recent years, and it is encouraging to learn from the recently issued report of the Governing Body of the Lister Institute that by work in which the Medical Research Council, the Ministry of Health, and the Institute have been concerned a method of separating the globulin of human serum has been developed which is suitable for large-scale production. Therapeutic trials indicate that the products obtained by these methods contain measles antibodies. We understand that the later clinical trials continue to show promise, and there would now appear to be good grounds for hoping that, in this country also, gamma globulin will become available in due course for the control of measles, although further research is required and production difficulties have yet to be faced.

### DEAFNESS IN YOUNG CHILDREN

In a Report issued in 1938 by the Board of Education on defective hearing in children it was estimated that in England and Wales there were nearly four in every 1,000 of the school population whose hearing was so impaired that in ordinary circumstances they were unable to hear their teacher's voice at school. Some (1 in 1,000) were quite unable to hear speech in any circumstances, while the remainder, by means of amplifiers or by sitting near

the teacher, were able to hear something, if not all, of what was said in class.

Deafness in young children is never an obvious defect though it may seriously retard the development of speech and intellect. Consequently the true cause of backwardness in a deaf child may not always be appreciated during the earliest formative years, even though a child be almost totally deaf. When the deafness though severe is not complete a child may respond to loud sounds in everyday life while being deaf to speech. In such a case any backwardness in speech and intellectual development may be attributed to causes other than deafness, and remedial measures employed that are both inappropriate and ineffectual. Thus the importance of early ascertainment of the nature and extent of the deformity handicapping a child with defective hearing cannot be overemphasized, though no one with experience of deaf children would underestimate its difficulty.

The pioneer work of Dr. and Mrs. Ewing has done very great deal to improve both the ascertainment and education of the child with defective hearing, but the still remains the problem of measuring the amount of residual hearing in a young child suspected of being deaf. It is often impossible to sustain the interest of a young child, even with normal hearing, by the conventional test so that it may be difficult to decide whether or not response to a sound-test is due to lack of interest or to inability to hear. The use of sound stimuli likely to attract a young child (bells, musical pipes, drums, etc.) helps to overcome this difficulty, but there still remains the problem of actually measuring the hearing. To do this Dix and Hallpike have evolved a technique whereby young children can be made, with a minimum of persuasion and explanation, to respond as soon as they hear the test tone of a pure-tone audiometer. In this way a quantitative assessment of hearing is made possible, and the "peep-show" technique which they describe in this issue of the *Journal* may well become the standard method of testing hearing in young children. Up to now it has not been possible for reasons already mentioned to carry out a satisfactory pure-tone audiometer test on a child under 7. The peep-show technique offers the possibility of an accurate test that can be carried out quickly and without difficulty, and it will be of great interest and of practical value to all who are concerned with child health and education.

### MORBIDITY ASSOCIATED WITH THE INDUCTION OF LABOUR

Thompson<sup>1</sup> has stated that the induction of labour involves the minimum of risk when the patient is at term, the head is engaged, the cervix is effaced, and dilatation has begun. When such conditions are fulfilled, however, induction of labour is not often required. In a study of the morbidity associated with induction in 500 cases, Roblee<sup>2</sup> found the combined maternal and foetal morbidity to be 25%, as compared with 10.5% in a similar number of normal spontaneous labours. This grouping together of maternal and foetal morbidity is not altogether satisfactory, and it should be noted also that the figures given have been corrected. Roblee ascribes the increase in morbidity largely to "the forcing of labour before the cervix, lower uterine segment, and uterus have been prepared for labour." Lacerations of the cervix were three times more frequent in the morbid than in the non-morbid cases, but their incidence could be reduced by 75% by eliminating the use of pituitary preparations from the procedures used for induction.

<sup>1</sup> *Calif. West. Med.*, 1938, 49, 358.

<sup>2</sup> *Amer. J. Obstet. Gynec.*, 1947, 53, 382.

The morbidity rate was found to be increased in proportion to the length of time between induction and onset of labour and with the duration of labour. It was two and a half times greater in primigravidae than in multiparae, and relatively higher in patients under 25 years of age. The highest morbidity (80%) was associated with attempts to induce labour after spontaneous rupture of the membranes, but in nearly half of the cases bags or bougies had been employed. The author did not determine morbidity in relation to the method of induction, but a study of his tables shows that, irrespective of the indication for induction, morbidity was increased by the frequency of employment of bags and bougies—methods which have been largely discarded in this country. The lowest morbidity (14%) was associated with induction within two days of the estimated date of confinement for no reason other than the convenience of the patient or the obstetrician. It is noteworthy in this respect that the incidence of induction was 10.2% for private patients, against 0.8% for general ward patients. Roblee views with disfavour the induction of labour for cephalo-pelvic disproportion, for suspected postmaturity, or for the convenience of the patient or attendant, although the last was the indication in 150 of the 500 cases. He finds the chief justification for induction in cases of toxæmia. In this country there has been in recent years a similar trend away from the induction of premature labour for contracted pelvis, although some still consider that when there is only a moderate degree of disproportion the results compare favourably with those of a trial of labour.<sup>3</sup>

Roblee's 500 cases include 300 which date from before 1935, and it might be expected that the morbidity in cases of more recent vintage would reflect modern advances in technique and in the prevention and treatment of infection. The morbidity in 150 cases in 1944, however, was as high as 20%. But, as Roblee asserts, the factor which will effect the greatest reduction in morbidity is the careful selection of cases according to the indications, the local condition, and the general health of the patient. He thus comes to the same conclusion as Thompson, that only in patients who are entering the threshold of labour can induction be carried out without risk. Finally, Roblee draws attention to recent work by Lyon<sup>4</sup> which suggests that knowledge that this threshold has been reached can be obtained by determining whether the antepartum decline in urinary pregnanediol excretion has begun.

### TOXICOLOGY RESEARCH

A new advisory committee has been formed to assist the Medical Research Council in the promotion of research into toxicology, with particular reference to industrial hazards. The following have been appointed to serve on it: Prof. G. R. Cameron, F.R.S. (chairman); Prof. J. H. Gaddum, F.R.S.; Dr. Donald Hunter; Mr. F. C. MacIntosh, Ph.D.; Dr. E. R. A. McEwether; Prof. R. A. Peters, F.R.S.; Mr. J. Davidson Pratt, B.Sc.; Dr. J. R. Squire; Mr. J. Walker, D.Phil.; Dr. J. M. Barnes (secretary).

In order to carry out experimental work on toxicology the Council have recently established at the Chemical Defence Experimental Station at Porton, Wilts, by arrangement with the Ministry of Supply, a new Toxicology Research Unit under the direction of Dr. J. M. Barnes. For clinical investigations in this field the Council already have their Department for Research in Industrial Medicine at the London Hospital, under the direction of Dr. Donald

Hunter, and their Industrial Medicine Research Unit at the Birmingham Accident Hospital, under the direction of Dr. J. R. Squire. In appropriate circumstances, research in the subject may be promoted by the Council elsewhere, either within their own staff organization or by means of grants to independent workers.

### VAGINAL SMEARS AND UTERINE CARCINOMA

The possibility of applying vaginal smear studies to the diagnosis of uterine carcinoma was first realized by Papanicolaou in 1928, but he did not follow up the suggestion until 1938 when, working first with Traut and later with Marchetti, he began a routine investigation at the Women's Clinic of the New York Hospital. The results and conclusions were published in a monograph<sup>1</sup> in 1943, and have been reviewed again recently.<sup>2</sup> Among 3,014 adult women examined 127 suffered from carcinoma of the cervix and 53 from carcinoma of the body of the uterus. By the vaginal smear technique a correct diagnosis was made in 96.8% of cases when the growth was cervical and in 90.7% when it was in the uterine fundus. Others, including Ayre,<sup>3</sup> report a degree of accuracy in diagnosis to within 5-7% for all types of genital malignancy. Not all workers, however, are convinced of the reliability of the method, and even its advocates emphasize that experienced pathologists require special training before they can interpret the smears satisfactorily, and that it is not yet a method for general application.

Although, up to the present, examination of vaginal smears has limitations so far as the diagnosis of uterine carcinoma is concerned, it is capable of other applications. Ruth Graham<sup>4</sup> used it to study the effects of radiotherapy on both normal and neoplastic cells. She examined 206 women treated with radium or x rays for carcinoma of the cervix—adeno-carcinoma in 27 and epidermoid carcinoma in 179; 35 patients were investigated by taking vaginal smears every one to three days before, during, and after treatment, 50 were investigated within six months of treatment, and the remainder at varying periods up to fifteen years after radiotherapy. It was found that the effect of irradiation is seen first in the normal cells of the vagina and cervix, sometimes as early as the second day. The basal cells, both inner and outer, show progressive alterations in shape and staining reactions and degenerative changes in the nuclei and in the cytoplasm, which becomes vacuolated; ultimately they become considerably enlarged and may assume bizarre forms. Similar effects also occur in the pre-cornified cells, and in the cornified cells, except that the pyknotic nuclei of the latter are little affected. A large increase in the number of leucocytes is also seen in the smear. A change in the malignant cells was usually apparent by the eleventh day, but the full effect was sometimes delayed until the seventeenth day after treatment and was similar in type to that seen in the normal cells—increase in size, vacuolation of the cytoplasm, and degeneration and breaking up of the nuclei: "it is often very difficult to say whether a radiated cell was originally malignant or benign." The average time taken for cancer cells to disappear completely from the smear was twenty-four days. Graham's descriptions of the effects of irradiation agree fairly well with those previously reported by workers who studied biopsy material except that, as she points out, abnormal mitosis is a less striking feature. This is because vaginal smears do not usually contain many cells undergoing mitosis.

<sup>1</sup> *Diagnosis of Uterine Cancer by the Vaginal Smear*, 1943, New York: The Commonwealth Fund.

<sup>2</sup> *Amer. J. Obstet. Gynec.*, 1946, 51, 316.

<sup>3</sup> *Ibid.*, 1946, 51, 743.

<sup>4</sup> *Surg. Gynec. Obstet.*, 1947, 84, 153.

<sup>3</sup> Barnett, V., *J. Obstet. Gynec. Brit. Emp.*, 1942, 49, 524.

<sup>4</sup> *Amer. J. Obstet. Gynec.*, 1946, 51, 403.

Perhaps the most interesting observation is that in a considerable proportion of cases neither the normal nor the neoplastic cells in the smear showed much reaction to irradiation. Out of the fifty cases studied one to six months after radiotherapy, 32 showed little if any reaction and in eighteen of these cancer cells were persistently present in the smear. This naturally raises the question whether it is possible to assess the prognosis in a particular case by the degree of response noted in smears taken during and immediately after treatment. This aspect of the problem is dealt with in a second article<sup>5</sup> describing 73 patients followed up for periods varying from six months to three years. Immediately after radiotherapy 36 were classified as showing a good response judged by vaginal smears, and of these three were untraced, five were dead, and 28 remained alive and free from signs of active growth at the time of report. Thirty-seven patients were assessed as showing a poor response to treatment, and the subsequent history of these was 26 dead, 8 alive but suffering from a recurrence, one alive and well, two alive and not examined but presumed well. Graham points out that in interpreting the response a sharp reaction on the part of normal cells may be more significant than a rapid disappearance of cancer cells from the smear. On the basis of these results it is suggested that the routine examination of vaginal smears permits an assessment of the prognosis with an 88% degree of accuracy, and that at an early stage in treatment. Moreover it is a method which can be easily applied, whereas the alternative—repeated biopsy—is impracticable. If this work is confirmed it should prove of the utmost value, because it means that in those cases where the cellular response is unfavourable and where the growth is not too extensive the patient can at once be given the chance which is offered by surgery.

### ENDOCRINE ALLERGY

In 1945 Zondek and Bromberg<sup>6</sup> performed skin tests with crystalline steroid hormones dissolved in purified olive oil. Previous work with aqueous extracts had been unsatisfactory, as a relatively long period of contact was necessary between the relatively insoluble hormones and the tissues. Of 165 women tested, 9.3% were found to be sensitive to the oil or to cholesterol and were therefore excluded. In the remaining cases the hormone skin tests gave a satisfactory indication of sensitivity, and this sensitivity to an endogenous hormone they term "endocrine allergy." That such a sensitivity exists is indicated by positive passive transfer tests, by generalized reactions accompanying some of the positive skin tests, and by their general findings. Following specific desensitization 80% of these cases were either free from symptoms or improved. In 32 normal healthy women the skin tests were all negative. Of 27 women suffering from diseases known or suspected to be allergic in whom symptoms appeared at, or were exacerbated by, menstruation, 70% gave positive skin tests. In a similar group in which the symptoms were not affected by menstruation or the menopause, only 7% gave positive skin tests. Cases of hormonal sensitivity were also found among women suffering from symptoms related to menstruation or the menopause but not usually classified as allergic.

More recently Zondek, Landau, and Bromberg<sup>7</sup> have recorded their findings in 6 cases (3 males and 3 females) of keratitis rosacea accompanying facial rosacea. As in the previous work, skin tests were done with testosterone, oestrone, oestradiol, progesterone, pregnandiol, corticosterone, insulin, and gonadotropin. In each case a posi-

tive reaction to testosterone only was obtained, all the other tests being negative. Allergy to testosterone in women is explained by the formation of testosterone by the adrenal. Treatment was by daily injections of gradually increasing doses of testosterone, starting with the minimum dose which gave a positive skin test and increasing to 1 mg., followed by the implantation of 10-mg. tablets of testosterone every few months. These cases, three of which are described in detail, were of four to twenty years' duration and were refractory to accepted methods of treatment. Specific treatment promptly relieved them of their subjective symptoms and the limbal and corneal vascular dilatation was considerably improved and disappeared; there was also marked improvement of the facial rosacea. The implantation of testosterone was necessary to prevent relapse; excessive dosage caused exacerbation of the symptoms.

This work is of considerable interest, but, as the authors point out, the finding of allergy to endogenous testosterone in these few cases does not exclude the possibility that other endogenous hormones may act as allergens in some cases or that other factors are involved in the aetiology of keratitis rosacea.

### STANDARDS OF NUTRITION

The Council of the B.M.A. at its meeting last week decided to appoint a Special Committee "to consider and report on the problems of nutrition in this country, including current nutritional standards." It was in April, 1933, that the Association appointed a similar committee with a more precise reference: "To determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size if health and working capacity are to be maintained and to construct specimen diets." This committee's report was published as a special Supplement to the *British Medical Journal* of Nov. 25, 1933. The late S. E. Kaye Le Fleming, then chairman of the Representative Body, presided over the Committee, and its conclusions were generally accepted and widely quoted in the years before the war in any discussion of minimal standards. We described this earlier report as "of national importance." The wider task of the present Special Committee is perhaps of even greater importance. Only last week we pointed out in a leading article<sup>2</sup> that the recent food cuts would involve a reduction in terms of daily food intake per head from 2,870 to 2,700 calories, a figure authoritatively described as "probably too low." The 1933 committee was able to assume, without taking into consideration the question of food cuts, that "3,400 great calories have to be purchased as food to keep an adult male in health and working capacity." The report of the present committee, now being appointed, will be awaited with much interest in the light of the greatly altered circumstances prevailing in this country.

The Hon. Harold Nicolson will deliver the Lloyd-Roberts Lecture on "The Health of Authors" before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday, Nov. 11, at 5 p.m.

Sir Cecil Wankley will deliver the Bradshaw Lecture on "Vogue and Fashion in Abdominal Surgery" before the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Thursday, Nov. 13, at 5 p.m.

## HEALTH REGULATIONS FOR AIR TRAVEL

BY

R. H. BARRETT, M.R.C.S., D.P.H., D.T.M.&amp;H.

Deputy Director of Medical Services, British Overseas Airways Corporation

Medical practitioners are often asked for information on the health regulations in force for passengers travelling by air to foreign countries. It may therefore be of interest to discuss the quarantine procedure as it affects passengers and aircraft leaving the United Kingdom on international flights.

The times taken from London to reach distant points in the world by air are now approximately:

Egypt ..	13 hours	Australia ..	2½ days
Canada ..	20 hours	South Africa ..	3 days
West Africa ..	1 day	New Zealand ..	4 days
India ..	1½ days	Hong Kong ..	6 days

The duties of the health authority are therefore becoming more difficult and responsible in view of the lack of clinical signs of infectious disease to be expected among the passengers examined. More reliance has to be placed on immunization, hence the insistence on the use of vaccines of known efficiency and on the production by the passenger of proof, in the form of certificates, that the operation has been performed satisfactorily. Certificates of immunity have in this way become an essential part of the formalities of air travel and seem likely to remain so for some time to come.

## International Convention for Aerial Navigation, 1944

The carriage of infectious disease from one country to another is controlled by this Convention, to which the majority of nations are signatories.

**Quarantine Procedure.**—The Convention defines the procedure and methods to be adopted by the signatories for the purpose of quarantine. The methods in use are: (a) immunization of persons by inoculation and vaccination against the five major epidemic diseases—yellow fever, smallpox, plague, typhus, and cholera; (b) medical inspection of suspected cases of infectious disease embarking or disembarking at an airport; (c) segregation or surveillance of infectious persons and their contacts; and (d) application of sanitary measures to passengers and aircraft, including the disinfection of persons, clothing, and bedding, and the destruction of mosquitoes and other vectors of disease where considered necessary by the health authorities.

**The "Convention" Diseases.**—The Convention is intended to cover all infectious diseases, including those carried by insect vectors (e.g., malaria) and in particular those major epidemic diseases referred to above, for which special measures are applicable and are set out in detail in the Convention. The incubation periods of these diseases and the periods of validity of the certificates of immunization agreed on internationally are shown in Table I.

TABLE I

Disease	Incubation Periods	Periods of Validity of Certificates of Immunization
Yellow fever ..	6 (India 9) days	For 10 days to 4 years from date of inoculation
Smallpox ..	14 days	For 14 days to 3 years from date of vaccination
Cholera ..	5 "	For 6 days to 6 months from date of inoculation
Plague ..	6 "	Not stated, but usually for 6 months from date of inoculation
Typhus ..	12 "	For 1 year from date of completion of course of inoculations

**Notification of Epidemiological Information.**—The Convention also provides for the collection and dissemination of epidemiological information to the signatories. The Interim Commission of the World Health Organization maintains an epidemiological information service at Geneva for this purpose. The service issues a weekly *Epidemiological Record* which gives the notifications concerning pestilential disease and similar information required by health services throughout the world. A *Statistical Supplement* is also issued every

month giving tabular information concerning notifiable diseases and vital statistics. Our Ministry of Health issues a *Weekly Record of Infectious Diseases at Ports, or other localities at home and abroad*. From these sources, and from information sent to airline corporations direct from overseas stations concerning local health regulations, it is possible to deduce the requirements for a passenger on any particular journey.

## Health Regulations Affecting Passengers

**Inoculation and Vaccination.**—The number of inoculations or vaccinations required by a particular passenger depends on the route he will fly. It will be necessary for him to comply with the regulations of each country in which he lands as well as those of the country of departure and of his destination. The regulations, however, usually make a distinction for a passenger who is only in transit through a country and not disembarking into it, and in the former case an alleviation of the rules is sometimes permitted. Health authorities are naturally anxious to prevent the entry of a person incubating any disease into a country where conditions are particularly favourable for its spread. This is the case in India, where regulations against the importation of yellow fever are very stringent in consequence of the presence of the *Stegomyia* mosquito. Similarly in Australia special precautions are insisted on against smallpox.

**Variation in Validity of Immunization Certificates.**—The periods of validity of certificates of inoculation and vaccination as shown in Table II vary in certain countries, and it is necessary to ensure that each passenger is in possession of certificates that are valid for all countries in which he will land during his journey. It would of course simplify the procedure for passengers if all countries would agree to accept the same periods of validity.

TABLE II

Disease	Convention Validity	Limits of Variation*	
		Maximum	Minimum
Yellow fever ..	10 days/4 years	15 days/2-4 years (India)	15 days/2 years (Madagascar)
Smallpox ..	14 days/3 years	21 days/2 years (Egip)	12 days/1 year (Thailand)
Cholera ..	6 days/6 months	14 days/6 months (Abyssinia)	6 days/3 months (Hong Kong)
Plague ..	None stated	5 days/2 years (Cyprus)	6 days/3 months (Hong Kong)
Typhus ..	—/1 year	12 days/1 year (Lebanon)	8 days/6 months (Cyprus)
Typhoid ..	None stated	6 days/1 year (Burma)	6 days/3 months (Java)

\* Calculated from date of completion of inoculation or of vaccination.

**Forms of Certificate.**—The Convention recommends that certain prescribed forms of certificate should be used for the purposes of travel by air. Airline companies sometimes print and issue these certificates to their passengers on request. These forms, or copies of them, should be used, since certain countries insist on the use of the Convention certificates and may refuse to accept any other as valid, with resulting delay and inconvenience to the passenger. It is important, therefore, that the certificate should be completed in all details; if an official stamp be affixed it will add to the value of the document.

**Notification of Health Regulations to the Passenger.**—Inoculation and vaccination required by regulations are notified to the passenger through his travel agency, and he should lose no time in consulting his doctor in order to have them completed before starting the journey. It is important that the passenger and practitioner should take into account the interval of time that must elapse before the certificates of these operations become valid. These periods are referred to in Tables I and II. The consequences to a passenger who is not in possession of the requisite certificates may be a refusal to permit embarkation, an enforced period of quarantine at the port of disembarkation, or refusal of permission to land.

**Precautionary Inoculation and Vaccination.**—Practitioners may be asked what inoculations and vaccinations are recommended as health precautions in addition to those required by the regulations. In general, vaccination against smallpox and inoculation against the typhoid group should be recommended to any person proceeding abroad. Other inoculations need be

advised only when epidemics are known to be in progress, and this information can be ascertained from any of the publications mentioned above.

**Health Regulations for Entry into the United Kingdom.**—Passengers are required to provide certain details of their travel during the previous 14 days, and are then given a "warning card" to hand to their doctor should they fall ill within the next 21 days. The card notifies the doctor that the patient has come from abroad and may be suffering from a notifiable infectious disease, and requests him, if the diagnosis is confirmed, to notify the local medical officer of health.

**Personal Declarations of Health.**—These should be completed by each passenger before arrival at a foreign port. Their purpose is to trace the movements of passengers during the period covering the longest incubation period of the Convention diseases, which is that of smallpox—i.e., 14 days. They should be completed and signed before the aircraft lands. The steward usually distributes these declarations in ample time for this to be done.

**Medical Inspection of Passengers.**—Passengers who have been in contact with an infectious disease or who are suspected of having contracted it may be required to undergo a medical inspection followed by observation in a hospital or surveillance at their place of residence. Under the Convention their persons and personal effects may be cleansed or disinfected according to the circumstances. Passengers who present a clean bill of health and have the necessary valid certificates of immunity are not subjected to any delay for quarantine reasons.

### Clinical Details of Inoculations and Vaccinations

The following details of dosages for inoculations may be of value to practitioners. The dosages and instructions are those used in this Corporation in consultation with the Wellcome Laboratories.

(i) **Yellow Fever.**—The only vaccines so far recognized internationally for inoculation against yellow fever are those prepared by: the Rockefeller Foundation and the U.S.A. P.H. Service Laboratory, Montana, in the U.S.A.; the Wellcome Research Institution, in London; the South African Institute of Medical Research, in Johannesburg; and the Pasteur Institute, Dakar. No other vaccines have yet been accepted for the purposes of inter-

by their travel agents of the most convenient medical sources which approved yellow fever inoculations may be obtained.

(ii) **Cholera.**—Two injections are given at 10 days' interval, sisting usually of 0.5 ml. and 1 ml. respectively for adults, children under 12 the doses are 0.2 ml. and 0.4 ml.

(iii) **Typhus.**—The adult dose is three injections of 1 ml. at 7 intervals, and is used for all ages down to 12 years. From 7 years the dose is 0.5 ml., and from 2 to 7 years 0.33 ml.

(iv) **Plague.**—This vaccine is apt to cause some reaction, a given only in the presence of an epidemic or where health reactions require it. The adult dose consists of two injections at week's interval. The gradation of dosage for children should that recommended for typhoid (T.A.B.).

(v) **Typhoid (T.A.B.).**—Doses recommended for alcoholized vaccine: Adults: first dose, 0.25 ml.; second dose, 0.5 ml. Children under 12 should receive vaccine two-fifths of the full strength follows: From 6 to 12: first dose, 0.25 ml.; second dose, 0.5 ml. From 2 to 5: first dose, 0.2 ml.; second dose, 0.4 ml. The injections are separated by a minimum interval of 10 days.

(vi) **Smallpox.**—The method used is the making of one deep scratch, then applying lymph and making a second scratch through the lymph.

The interpretation of vaccination reaction may be described as follows:

Day of Vaccination	Reaction		
	Primary Vaccinia	Accelerated (Vaccinoid)	Reaction Immunity
1			
2			
3			
4			
5			
8			
11			
16-21	Papule Vesicle Pustule Scab Scab off	Papule Vesicle Pustule Scab Scab off	Papule No vesicle Rapidly fading
Immunity of individual before vaccination	Nil	Fair	Good

**Inoculation and Vaccination of Children.**—Children under 2 years of age may be vaccinated against smallpox and inoculated against yellow fever unless there are medical indications to the contrary. The remaining inoculations are not recommended for children of this age unless there is an epidemic progress or health regulations make them essential.

### Health Regulations affecting Aircraft and Crews

The same regulations apply to aircrews as to passengers. It is customary, however, for aircrews to have their health certificates always up to date in order to avoid delays and to ensure that they are available for service on any route without additional medical preparation. Airlines have their own organization for carrying out these inoculations at regular intervals.

(i) **Sanitary Measures.**—An aircraft may act as a carrier of disease in several ways. In addition to the passengers, who may be incubating human diseases, it may carry vectors in the form of mosquitoes, lice, fleas, other insects, or infected rodents. It may also carry infection in food, water, cargo, or sewage. In addition to the sanitary measures applicable to passengers there are special measures for the aircraft itself. The usual process of disinfection of the interior of aircraft and cleansing of containers and water supply present few difficulties.

(ii) **Disinsectization.**—The killing of mosquitoes or other insects known as "disinsectization" or "disinsection," however, requires special mention. This measure is required to be applied to aircraft whenever it arrives or departs from an airport in a malarious zone or a malarial district. It is best done with the aircraft loaded but without passengers or crew on board. The method employed in the U.K. for aircraft flying to India is as follows.

The interior of the aircraft is sprayed with a pyrethrin aerosol containing not less than 0.4% pyrethrins, or not less than 0.2% pyrethrins and 3% D.D.T. applied from an aerosol dispenser at a rate of not less than 15 seconds per 1,000 cu. (28.3167 cu. metres) of free air space. The dispenser used is the Westinghouse type, and the cap is removed completely during the process. All openings in the aircraft are kept tightly closed during the spraying and for a period of five minutes thereafter.

(iii) **Certificate of Disinsectization.**—A certificate of disinsectization issued under the authority of the Ministry of Health in

TABLE III

City	Address	Telephone Number	Times of Attendance
London	Wellcome Research Institution, 183-193, Euston Road, N.W.1	Euston 4668	Mondays and Fridays, 10.30 a.m.-12.30 p.m. Tuesdays and Thursdays, 4-5 p.m.
Aberdeen	City Hospital Laboratory, City Hospital, Urquhart Road	Aberdeen 2242 Ex. 11	Thursdays 3 p.m. or by prior arrangement
Birmingham	Regional Blood Transfusion Centre, 17, Highfield Road	Edgbaston 1182	Tuesdays 2-3 p.m.
Bristol	Regional Blood Transfusion Centre, Southmead Hosp.	Bristol 68021	Tuesdays 2-3 p.m.
Cardiff	Regional Blood Transfusion Centre, Newport Road	Cardiff 4521	Mondays 2.30-3.30 p.m.
Edinburgh	Bacteriological Dept., Edinburgh Royal Infirmary, Edinburgh, 3	Edinburgh 26031	Mondays and Wednesdays 2.30-3.30 p.m.
Glasgow	Public Health Clinic, 20, Cochrane Street, Glasgow, C.1	Glasgow Central 9600 Ex. 302	Fridays 2.30 p.m.
Leeds	Regional Blood Transfusion Centre, Meanwood Park Colony	Leeds 52651	Fridays 2-3 p.m.
Manchester	Regional Blood Transfusion Centre, Manchester Royal Infirmary, Oxford Road	Ardwick 3832	Tuesdays 2.30-3.30 p.m.
Newcastle-upon-Tyne	Regional Blood Transfusion Centre, 78, Jesmond Road	Jesmond 2992	Mondays 2-3 p.m.
Oxford	Southern Regional Blood Supply Depot, Churchill Hospital, Headington	Oxford 61316	Mondays 2-3 p.m.

national certificates. The vaccine must be kept at a temperature between 0° C. and 4° C. The dosage is made up to an injection of 0.5 ml. with water or normal saline for an adult. Children under 2 years receive half the normal dose. A list of official yellow fever inoculation centres notified by the Ministry of Health is shown in Table III. This list is not exhaustive, and passengers are informed

Britain, using the method described above, is accepted by the Indian Government as proof of the aircraft being "clean" in respect of yellow fever. Passengers from the U.K. in an aircraft so treated would therefore not require to possess certificates of immunity to yellow fever on entering India unless they had been in a yellow fever area within the previous nine days.

(iv) *Regulations for Aircraft Entering India.*—The Indian Government defines the sanitary state of aircraft entering India in respect of yellow fever under the Indian Aircraft (Public Health) Rules, 1946. This may be summarized as follows: (1) "Suspect" if it arrives in India from the west. (2) "Infected" if it has on board a case of yellow fever or it has not been subjected to the prescribed measures since the disposal of such a case, or if there is a person on board who has been in a yellow fever area within nine days and does not possess a certificate of immunity, or if the aircraft has come from a yellow fever area and has not been disinfected. Similar definitions are applied to aircraft in relation to the other four Convention diseases, and the special measures that may be applied are given in detail in these regulations and in Part III of the Sanitary Convention.

*Aircraft Declaration of Health.*—This is required under the Convention to give information on the sanitary condition of the aircraft and its passengers and cargo. The declaration amplifies the information formerly given in the bills of health and is analogous to the "declaration of health" now in use for shipping. It is required to be signed by the commander of the aircraft and handed to the health authority on arrival at an airport.

### Summary

The main features of the quarantine position as it affects commercial flying are briefly surveyed. If the methods employed to control the entry of disease into countries by air appear to assume an importance not hitherto known in sea or land transport, it should be remembered that practically all international flights are, from the point of view of quarantine, well within the incubation period of the major epidemic diseases.

Relaxation of health controls could only come about through a general raising of the standard of hygiene in all countries and the elimination or more effective control of pestilential diseases. Consideration might be given, however, to the standard of hygiene of airports used on international flights. The 1944 Convention gives the definition of a sanitary airport, but the standards of hygienic requirements might well be extended to include immunization of personnel serving at the airport and the establishment of a zone surrounding the airport which would be completely epidemic-free and be built to the best hygienic standards so that passengers and aircraft in transit could land without risk of infection. Such a scheme would do much to relieve passengers of the health requirements now enforced for transit passengers.

Standards similar to those enforced for immunization also require to be laid down for the disinsection of aircraft. Methods of disinsection vary in certain countries, with the result that a certificate issued at one airport on a route may not be valid for the whole route. This is a cause of much duplication of work and expenditure of materials. An agreed standard would serve to satisfy all authorities and remove a source of delay and inconvenience.

It is to be hoped that the joint consultation of the World Health Organization and the International Committee on Aerial Organization will prove a fruitful source of agreement and so permit of a reduction of the controls without loss of efficiency.

I am indebted to Sir William Tyrrell, Director of Medical Services, British Overseas Airways Corporation, for permission to publish this article, and to Colonel P. G. Stock, Brigadier H. T. Findlay, Brigadier J. S. C. Boyd, and Air Commodore J. Kyte for their kind help in preparing it.

The summer number of *Nutrition: Dietetics: Catering* (subscription for 4 issues 10s., from Newman Books, Ltd., 356-366, Oxford Street, London, W.1) opens with an address by Sir Jack Drummond on the "Scientific Approach to Food Problems During the War." He reviews the nutrient requirements of different types of workers, their deficiency in the nation's food supply, and the best food from which to obtain them. He also discusses the most suitable composition of bread. Prof. J. R. Marrack gives a general account of folic acid, and there follows a speech delivered at the Oxford Conference of Dietitians in 1945 by Sir John Boyd Orr, now Director General of F.A.O., on "The British War Food Policy and the Future World Food Policy." Other writers discuss nutrition in industry, school meals (including a short account of breakfast in Norwegian schools), and the catering system at the Radcliffe Infirmary, Oxford.

## ECONOMICS OF PUBLIC HEALTH

Dr. F. Hall chose this subject for his presidential address to the Society of Medical Officers of Health on Oct. 23.

He said that the appointment of the first medical officer of health was "a business proposition," as evidenced by the salary of £750 per annum paid to Dr. Duncan. The wealth of a nation lay in the physical and mental energy of its people, and it was not just a coincidence that in this centenary year there had been placed upon the Statute Book an Act for the establishment of a National Health Service. The administrative provisions of the Act had been noted by medical officers of health with a certain amount of apprehension and disappointment, in that the local government organizations had been given what appeared to be a minor part to play in carrying out the purposes of the Act.

Dr. Hall reviewed briefly the sequence of events which led to the Act. Public, voluntary, and private medical services had worked in close association, and especially during the recent war in matters of civil defence and in the Emergency Medical Services. The success achieved and the administrative pattern evolved probably contributed to the decision taken during the war that a National Health Service should be established.

New statutory administrative bodies had now been created, and the ease with which this had been accomplished was a striking example of the position Parliament occupied as the supreme policy-making and administrative authority. By the decision of Parliament, well-organized and apparently stable local government authorities would lose many of their health functions, and the voluntary hospital system, with its long tradition of service, passed under a new form of control. This demonstration of what was the real power in the constitution had no doubt been observed by medical officers of health with "the enthusiasm of good democrats."

The factual reports of the hospital surveyors had drawn attention to the low standards, in matters of premises and equipment, of a great many of both the voluntary and the rate-provided hospitals. They could have stated with equal truth that the responsible authorities were for the most part quite unable to face the financial burdens which the modernization of these hospitals would have involved. The transfer of administrative function from one type of authority to another neither removed the necessity for such modernization nor materially altered the cost. An alteration in the responsibility for these services would have an important effect, however, in that the expenses incurred by treating sickness in hospitals and other institutions would not be partly hidden by gifts, either of money or of service, but would appear in the nation's accounts with due publicity. Here then was an economic factor in public health which would call for renewed attention by administrators.

Efforts to make the nation "health conscious" would perhaps be more successful when public health authorities obtained a greater degree of support from the organizations and associations which represented the industrial and commercial undertakings. To make people living under slum or near-slum conditions "health conscious" was a formidable, if not an impossible, task. The evacuation of overcrowded districts during the war plainly indicated that progress in this matter had been slow and that new methods of approach should be attempted.

He had stressed the economic aspect of public health work because in the difficult times before this country it was clearly necessary that in using the scientific and financial resources which might be available certain priorities should be observed. Much remained to be accomplished, and there was no easy way of preventing ill-health. Of the measures proved useful there were some which could be carried out by central authorities, but the majority demanded local investigation and personal contact with the people, and formed the day-to-day work of public health officers. Further improvements in the productive capacity of the nation would be most profitably effected by extending and intensifying this form of activity. Many branches of medical science were involved, and team work was clearly essential.

## Correspondence

### Health Centres

SIR,—The medical profession has approved of the conception of health centres with certain provisos to safeguard the public and the medical men who may work in them. In fact the idea originated in the profession, but doctors foresaw the dangers of such centres degenerating into miniature hospital clinics or becoming the playthings of local politics or the dead ends of bureaucratic control and interference. The essential safeguards are that in any health centres the doctors working there should do so freely and by voluntary association or in partnership, and further that these doctors should either own or rent the building and major equipment and most certainly own all personal equipment, otherwise they risk becoming the serfs of Government. As Carlyle says, "Without his tools man is nothing." Another important proviso is that health centres must be made suitable to the particular locality, as obviously one in a town near to hospital facilities need not be so elaborate in scope as one in the country. The variations in size, type, and equipment must be very great, even to the inclusion in some districts of casualty and observation beds.

I have had the good fortune to work in a country practice in a mining valley in Wales, and for close on twenty years in a large partnership practice in a county town, which has in fact been run on health-centre lines. From this experience and from what I know of medical friends who practise in different types of town and country practice I am convinced that the basis on which the health centre, wherever situated, should be built up should, with moderations according to local needs, be as described below.

If possible the doctors should be in partnership and should mutually agree upon their individual shares and should own their goodwill. If a partnership cannot be formed there must be mutual agreement on the formation of the team, as no mere appointee, possibly disliked by, or unsuitable to, or unfitted to the team, should be foisted on the others by a local or central authority. Friendly team work is essential to the welfare of patients and doctors. The doctors should own or rent the building or parts thereof. Each doctor should have his own consulting room and personal equipment and be part-owner or part-renter of such major equipment as may be required. Waiting rooms should be large, comfortable, and either communal or not according to local circumstances, and there should be appropriate examination rooms, dressing rooms, minor operating rooms, and laboratory. There should be a full-time secretary in charge of the required number of assistant secretaries, receptionists, and surgery maids. The secretary should see to the organization of the secretariat, card-keeping, filing, visiting lists, calls, and appointments, etc., and keep the accounts of the team and expenses of the health centre. The secretary should be given wide discretionary powers by the medical team and owe her allegiance to the team; further, the secretary should, if possible, live in the flat above or in the health centre.

A fully trained nurse may be required in a whole-time capacity in a large country health centre. Each member of the medical team should take up a part-time specialty, so that his services are available to the team for consultation, treatment, or operations, but all should do general practice as well. Thus in a team of five one might specialize in general surgery, one in eyes, one in ear-nose-and-throat work, one in midwifery and gynaecology, and one in children's cases; and if possible each should hold an appointment in his specialty at a local or near-by hospital in order to keep entirely up to date. An agreed rota should be drawn up by the team for half-days, week-ends, holidays, second-call duty, and postgraduate work; and, in my view, in a team of four there should never be less than two on duty at any one time. Obviously there will be many times when all will be on duty.

By this means the team keeps fit and happy and able to work hard, while the patients get the benefit of this and get to know, to trust, and to rely upon the team and its members, and come to realize that they are not being let down if they cannot see Dr. A when he is away or ill, because they know and have been treated by Dr. B or C or D on various previous occasions. This family feeling and personal touch of friendship and loyalty is essential to good medical practice in these abominably materialistic days. A large team should include at least one woman doctor and, according to the locality, a medically qualified dental surgeon. Both for town and country health centres of any type consultants should be available, either for domiciliary visits or special consultations at the health centre according to need. An x-ray and pathological service could be included

in the health centre if suitable hospitals were too far away, as in mid-Wales, for example.

I am certain that along these broad lines which I have indicated health centres could be made a great success and be of immense benefit to the people, both in preventive and curative medicine, because above all the medicine of the future must be human and not merely humane. The freedom, honour, and integrity as well as the physical and mental well-being of the patients are in the doctor's hands, and if the doctor is not a free man and does not remain the arbiter between the patients and any third party then the patient is inevitably lost in totalitarian oppression. "For what shall it profit a man if he shall gain the whole world and lose his own soul?"—I am, etc.,

Reading.

S. F. LOGAN DAINE.

### Aetiology and Prophylaxis of Puerperal Sepsis

SIR,—Every throat surgeon must be particularly interested in a few of the many facets presented in the fascinating survey of "The Aetiology and Prophylaxis of Puerperal Sepsis" by Prof. Joseph W. Bigger (Oct. 18, p. 599). It is not only the throat (tonsil and pharynx) which harbours in great numbers the specific virulent strain of the *Streptococcus pyogenes*, the cause and spread of puerperal sepsis. Such a focus has long been recognized, coped with, and the danger eliminated. There remains, however, in an infected maxillary antrum (as a sole lesion or part of a suppurative pan-sinusitis) another insidious and frequently overlooked, but nevertheless a recurrent, source of the virulent causal organism. The pharynx is merely the catchment area of the nasal passages, which are continually polluted from the cesspool of streptococcal pus in the antrum. The infection persists for a period far beyond that of any acute transient primary throat streptococcal lesion. Some years ago, in discussing puerperal sepsis with a colleague, he informed me that in every necropsy performed by him where the cause of death was infection after labour or a septic abortion he had never failed to find pus in the maxillary antrum.

The maxillary antrum is a cavity in which pus can be easily overlooked, a fact attributable to the mildness of the symptoms an empyema there commonly produces. The complacency with which such a condition once diagnosed is left untreated is staggering. This suppurative lesion appears to have received a special dispensation from the universal surgical rule of *ubi pus, ibi evacua*. The infected antrum case is permitted to remain ambulant, and probably untreated, to constitute a far more dangerous streptococcal "throat" carrier. The throat surgeon should also read with interest, profit, and admiration of the stringent precautions adopted to prevent the entry and outbreak of infection in the obstetric wards and of the great and sustained success achieved—a high standard taken for granted by contemporaries.

Those to whose lot it falls to supervise any large and busy ear-nose-and-throat surgical ward soon become only too familiar with the unpleasant regularity with which a dangerous form of spreading cross-infection rears its ominous head—an infection conspicuous by its absence when similar cases are nursed in a single room. The designers of the ear-nose-and-throat ward in the new era would do well to ponder on Prof. Bigger's remarks that "the ideal method of avoiding case-to-case transfer of infection is to provide a separate room for each woman admitted." Such an arrangement would go far to control at its source the spread of any infection.

General wards for surgical E.N.T. patients should find no place in the hospital of the future. If at all necessary the wards should be designed solely to house convalescent patients. For over twenty years I have stressed the inherent dangers of performing operations such as removal of tonsils and adenoids, submucous resection of the nasal septum, and, more recently, the fenestration of the labyrinth on patients housed in a large busy ear-nose-and-throat ward. Operative morbidity and serious complications are rife especially at certain seasons of the year, and many such an operation of convenience is but the prelude to a period of pyrexial anxiety terminating in a subsequent emergency operation for a dangerous infective complication. If the measures of prophylaxis against hospital infection described by Prof. Bigger are adopted in the ear-nose-and-throat wards of the new hospitals which are to arise phoenix-like from the ashes of the old, this stigma of recurrent epidemics and cross-infection should be a thing of the past. But the price of success will be constant bacteriological vigilance.—I am, etc.,

London, W.1.

N. ASHERSON.

### Bornholm Disease in the South Pacific

SIR.—Drs. W. M. Jamieson and D. M. Prinsley (July 12, p. 47) state that they are aware of only one previous report of an outbreak of Bornholm disease in the Tropics (McDaniel, 1944). Two epidemics of Bornholm disease occurred in South Pacific islands, one in Tonga and the second the following year in the Cook Islands. Tongatabu, the main island of the Tongan Kingdom, lies in about 20 degrees south latitude. It is a low coral island and, although within the Tropics, the climate is not excessively hot nor is the rainfall great. The hottest months of the year are January to March.

In February, 1946, the first case of Bornholm disease was brought to the hospital. This was a Tongan boy, aged 10 years, who collapsed on the road. The Tongan medical practitioner who first saw him suspected an acute abdominal emergency because of pain, tenderness, and rigidity of the right side of the abdomen. Examination showed that the signs were more marked in the upper right quadrant and that they lessened on passing down to the right iliac fossa. The temperature was 101° F. (38.3° C.) and there were no physical signs above the diaphragm. A tentative diagnosis of Bornholm disease was made, and the subsequent progress confirmed the diagnosis. This proved to be the starting-point of an epidemic which affected from 20% to 40% of a population of 16,000 people, mostly Tongans. The European population in Tonga is small, but they suffered equally with the native population.

The clinical picture did not differ from the classical description—sudden onset with diaphragmatic pain and fever. In a fair proportion of cases shoulder pain was noted, and in some here were also abdominal pain and chest pains. The temperature range varied, but readings of 104° F. (40° C.) were not uncommon. The acute stage generally lasted two to three days and recovery was rapid and complete. There were no deaths, no complications, and no sequelae. The epidemic lasted about four weeks in Tongatabu. It spread to other islands of the Tongan group. Reports from several of the out-stations mentioned numerous cases of "influenza with pleurisy." These were obviously cases of Bornholm disease.

So far as could be ascertained, none of the Tongan medical practitioners had ever seen or heard of similar cases, so that within recent times Bornholm disease, at least in epidemic form, has not occurred in Tonga. Tonga has free communication with the outside world by a regular monthly steamer from New Zealand. There is also a plane service from New Zealand, via Fiji, and occasional cargo boats from the Pacific coast of North America.

The second epidemic occurred in Rarotonga, the main island of the Cook group. Rarotonga lies about 600 miles due east of Tongatabu and in the same latitude. The rainfall is higher than in Tonga and the climate is warmer, although for a tropical island it is not excessive. The first case of Bornholm disease to be seen occurred early in January, 1947, but it was not until late in February, 1947, that the disease became epidemic. By the end of March the epidemic had burnt itself out. Clinically the cases seen were similar to those seen in Tonga the previous year, and the course of the epidemic resembled that of the Tongan epidemic. Rarotonga is served by a steamer from New Zealand and also by a weekly plane from New Zealand, which calls at Fiji, Tonga, and W. Samoa on the way. One of the native medical practitioners remembers a few cases of "pleurodynia" some years ago, but there is no record that the disease was ever epidemic.

Puka Puka is the most isolated of all the Cook Islands. It is situated in latitude 11 degrees south and is visited only once or twice a year. Puka Puka, or Danger Island, is a low coral atoll. At the end of March, 1947, the Resident Agent reported by radio an epidemic, described as "gastric influenza," which swept through the three villages on the island and finally died out in three weeks. There is no trained person on this island and it was difficult to get an accurate description of this sickness. The prominent symptoms appear to have been sudden onset, pain in the epigastric region, and fever. Mostly young people were affected, and recovery was complete in three days. The point of interest is that no ship had visited this island since October, 1946. This sickness may or may not have been Bornholm disease, but whatever the nature of the epidemic it is

hard to understand how it could have originated after six months of complete isolation from the rest of the world. Could the infective agent remain dormant for so long a period or could it arise spontaneously?—I am, etc.,

Rarotonga, Cook Islands.

FARQUHAR MATHESON.

### Anaesthesia for Head and Neck Surgery

SIR.—Dr. J. G. Bourne (Oct. 25, p. 654) has drawn attention to the use of *d*-tubocurarine chloride as an aid to endotracheal intubation. That *d*-tubocurarine chloride removes many of the difficulties associated with oral intubation cannot be doubted and has long been recognized, but I would question his method of administration. I agree with him that "it is difficult to predict the approximate dose of curare that is required for any individual." But emphatically the solution to this difficulty is not to give 20 mg. "quickly in one injection immediately after the thiopentone." Individual variation in the reaction to a given dose is characteristic of this drug, and more than one case of apparent idiosyncrasy has occurred. The single injection of 20 mg. into an anaesthetized patient seems therefore an unjustifiable procedure.

To render the administration as safe as possible Dr. John Halton and I have for long advised the following procedure. (1) The intravenous injection of a test dose of "tubarine," usually one-third of the estimated initial dose, followed by a pause of at least two minutes. The normal reaction of a healthy adult to this small dose (usually 5 mg.) is a sensation of heaviness of the eyelids, very occasionally diplopia, and little else. Anything in the nature of ptosis which *cannot be voluntarily controlled* is an excessive reaction indicating the need for caution in the further administration. (2) In the presence of a normal reaction the injection of the *d*-tubocurarine chloride is completed and followed immediately by (3) the dose of thiopentone. The induction of anaesthesia by this method has been carried out on many hundreds of patients, none of whom have complained of any unpleasant sensation before going to sleep.

The initial test dose has always given valuable information of the range of dosage likely to be required, and the administration of the *d*-tubocurarine chloride before the thiopentone produces a synchronization of the maximal effects of both drugs. This probably accounts for the fact that I have never had the slightest difficulty in intubating after 15 mg. of tubarine and 0.5 g. of thiopentone, a dose of each considerably less than appears to be required by Dr. Bourne.

I am glad that Dr. Bourne emphasized the need for full oxygenation of the patient after the induction prior to intubation. This gives added relaxation and, as he stresses, a little more time for introducing and fixing the tube. One wonders, however, whether the use of *d*-tubocurarine chloride is really required for operations of this type. In the average patient endotracheal intubation under vision can be performed rapidly and very satisfactorily under thiopentone and a local spray alone, and it appears to me that the upset of the respiratory function caused by *d*-tubocurarine chloride is unjustified for these comparatively superficial procedures.—I am, etc.,

Liverpool.

T. CECIL GRAY.

### Duodenal Ulcer and Priority Foods

SIR.—On more than one occasion attention has been called to anomalies in the schedule of diseases governing the issue of priority certificates. With one notable exception the schedule seems just and reasonable, but I am more and more appalled by the colossal amount of milk and eggs that is squandered upon patients with duodenal ulcer by granting them 2 pints (1.1 l.) of milk a day and priority eggs. In the course of a year the milk so cast upon the waters would probably float a battleship (albeit one of a pocket variety). In the schedule, I. D. includes gastric, duodenal, and anastomotic ulcers. Few would grudge priority to those with gastric and anastomotic ulcers, as their symptoms are more frequent and severe, and moreover in point of numbers they are relatively far fewer. The incidence of duodenal ulcers is very high. It has, indeed, become a somewhat popular malady—and no wonder!

Now, if there is one thing more constant than another in the practice of medicine it is the long intervals of complete freedom

from all symptoms enjoyed by patients with chronic duodenal ulcers. Surely there would be a large measure of agreement that there is no need for a patient, even during an acute phase of his duodenal, and far less during a chronic phase, to live exclusively, or even largely, upon milk and eggs. As a rule they can and do have a varied and extensive diet, and many of them are well covered and might reasonably be described as "comfortable" in appearance. If an exclusively milk-and-egg diet continued for, say, a year would cure their ulcers, it might justify such lavish awards, but we know perfectly well that it would do nothing of the sort. Furthermore, the schedule says "duodenal ulcer," not "acute duodenal ulcer," and we know that in the long intervals of freedom from symptoms the ulcer has rarely, if ever, permanently healed except where surgical measures have been adopted, and so all those who have at one time or another had an established ulcer may reasonably claim to come into the category. Indeed, as most of us know to our cost, once the patient's course has been set upon the "milky way" it is almost impossible to set a limit upon it. No infant was ever so difficult to wean as the men (they usually are men) who appear so regularly at three-monthly intervals for their certificates.

At this time of stringency to continue to grant 2 pints of milk a day and priority eggs to the duodenal ulcers, apparently in perpetuity, seems out of all proportion in the national economy and devoid of common sense. I believe that if duodenal ulcer was removed altogether from category I. D. it could be dealt with justly and adequately under II. C., and priority in eggs could be allowed during the relatively short acute stage. In this way I am confident that the scanty allowance for the general public could be appreciably improved.—I am, etc.,

London N.W.7.

A. H. MORLEY.

### The Extent of Neurosis

SIR,—Patients with functional rather than organic illness, it is commonly estimated, constitute from one-third to two-thirds of the claimants for general practitioners' attention. Considerable help towards the solution of their problems could be given by general practitioners' regularly devoting two afternoons a week to four or five patients for whose illnesses no materialistic interpretations suffice. It would quickly be evident that therapeutic listening alone produces effects, and further discoveries would follow in due course. Some more experienced colleague might before long be consulted, as psychotherapy has its effects on doctors as well as on patients. Observing the emergence of his patients' problems, the practitioner might find himself confronted by previously unrecognized problems of his own. But from the start any practitioner sufficiently concerned with the welfare of sufferers from functional illness would be satisfied that his time was well spent.

In support of this proposition, brief notes of six patients with whom in all fifty-six hours were spent are submitted.

### CASE REPORTS

*Case 1.*—Mrs. A, in her thirties, three months pregnant, complained of attacks of terror at night, with palpitation, following the birth of her fourth child. "I shot out of bed, rampaged round the house, not knowing what to do with myself, then got back to bed shaking and feeling that I was passing right out," she said. In the course of eight one-hour consultations the terror turned to nightmares, and the nightmares to memories and sweet dreams. Her exposure of herself to her when aged 6, and her father's death, her uncle's occasional drunkenness, and the general tenor of her miseducation had persuaded her that men such as her worthy husband did terrible things to women. But she is now radiantly enjoying the fifth terrible result of what men do to women. And her four children are finding life easier.

*Case 2.*—Mrs. B, in her twenties, with one infant, complained of heart attacks and fainting, for which she had earlier been invalided out of the Land Army. After eleven interviews her husband was wondering what had been done to transform his wife from a shrinking girl into a vigorous young woman. Mainly we had discussed her dreams and her ideals. She had been much attached to her churchwarden father.

*Case 3.*—Mr. C, in his thirties, had been rejected from the Army owing to essential hypertension. He could not stop worrying about his high blood pressure, which was 190/110 at his first interview. At the start of his seventh interview his B.P. was 138/95. He had been left alone in an air raid at the age of three, and had other sources of anxiety.

*Case 4.*—Mr. D. had been in the Army from 18 to 24 and had a lot to tell of his experiences. He was suffering from headache, poor sleep, inability to hold down jobs, and marital troubles. He told his tale, and felt a great deal better after ten discussions. Shooting of prisoners by his N.C.O. had not helped him.

*Case 5.*—Miss E, aged 20-odd, was suffering from tantrums, headaches, backache, and bedwetting. Her mother had died three years earlier and her father had remarried. Her place in the home the spoilt eldest child was gone for good. After eight interviews accepted this. Then she dreamt of a fortified breast-shaped island sinking into the sea, and her complaints forthwith ceased, and became a little less attached to her elderly boy friend.

*Case 6.*—Mr. F, in his forties, complained of recurrent eczema of the face. This particularly irritated him whenever he was wrong. He was also troubled by a very strict sense of right and wrong, childish origins of which we investigated. He began to see black and white were not the only colours in the world, and ceased, after twelve consultations, to suffer from irritation of flushed face.

These six cases are culled from some fifty to whom, in course of an initial year of psychotherapeutic endeavour combined with general practice, over 1,000 hours were devoted, further six patients conspicuously failed to derive apparent benefit from prolonged attention. Encouraging responses have come from the majority of the remainder, but this is sufficient exposure of the bare bones of some benefits to be derived from psychotherapy.

It has been long known that much may be done by a passionate inquiry into the lives of sufferers from functional illness and by dispassionate discussion of their problems, still general practitioners' surgeries remain crowded by men and women in need of understanding who get medicines and pills. This is no new problem, but it bears repetition as long its existence is at all ignored or denied. Sufficient recognition of its existence will, as is the case with patients' problems, do much towards reducing its deleterious effects.

Grateful acknowledgments are made to Dr. E. Grafton-Howe for his help and encouragement.—I am, etc.,

Ruislip, Middlesex.

WILLOUGHBY CLARK

SIR,—It is to be hoped that Dr. H. Crichton-Miller (Oct. p. 669) will not be prevented by "limits imposed by a letter in elaborating his ideas on the prevention of neurosis. His theme should be emphasized on all possible occasions until it may sink into the mentality of politicians and statesmen. It was under the stimulus of "fear" (in the psychologist's sense of the word) that the human race has evolved, and fear in one form or another has been responsible for most of the advances which human hands and brains have achieved. When the stimulus of fear is removed and milk-sop sociological ideas substituted, the poor moron is removed from his true place in the fringe of the herd and becomes the spoilt boy of his group and, alas, too often the pet of his doctor.

Under the more robust ideas of the pre-Socialist age human riff-raff was taken at its true worth to the herd. To it too often becomes the group standard above which none may aim (500 bricks a day). "Freedom from fear," with its fellow slogan "Safety first," may well become the mottoes of our so-called decadence.—I am, etc.,

Alverstoke, Hants.

W. H. EDGAR

SIR,—Why does Dr. H. Crichton-Miller (Oct. 25, p. 669) suggest that Socialism eliminates fear? In a *laissez-faire* economy fear was certainly present as he suggests, but in experience it is far from absent in such services as may be described as socialized. In local government, in municipal hospitals, in the fighting Services one sees quite a lot of fear of getting a bad mark, of not being in favour with superiors, and fear of responsibility, fear of employers' unions. If things come to such a pass that those who have the favour of the "machine" have lost their chance of employment, which is not impossible, then fear will be augmented. The simple-minded may be inclined to put their trust in the State. But do we find the State as honourable in its dealings as we would like to be ourselves? I think not. And if we cannot trust the State we experience fear.

There seems much to be said for maintaining a society in which those out of favour are not unduly penalized. But so trade unions think differently, and so do the rulers of Russia.

Many Russians in my care during the war, even those who had been wounded before capture, awaited their return home with extreme terror. Why?

I agree that social security, whatever it may mean, has tended to reduce effort for the reasons advanced by Dr. Crichton-Miller. Many economists suggest that the economic basis for this social security is crumbling, so we may soon see the next phase developing.—I am, etc.,

Barnet, Herts.

G. C. PETHER.

### Prognosis of Pleural Effusion

SIR.—Dr. Brian C. Thompson's reply to Dr. J. D. L. Reinhold's letter (Aug. 30, p. 348) prompts me to add my views on the point at issue in this important correspondence. A study of my cases in private and hospital practice during the last eight years goes to support Dr. Thompson's statement that "there was no evidence that differences in treatment of the original pleurisy affected the subsequent incidence of pulmonary tuberculosis." The study brings out two points conspicuously:

(1) The subsequent development of pulmonary tuberculosis is more common in those who show a "tuberculous diathesis." The latter can be recognized clinically to some extent from the history of tuberculosis in the family, relatively low weight, inelastic skin, dry hair, pallor, easy fatigue, "phthisical" configuration of the chest. Such persons are often styled by laymen as of "delicate constitution."

(2) Rest and sanatorium line of treatment have no effect on the prognosis. Under Indian conditions patients of pleural effusion, when afebrile and free from respiratory embarrassment, have to work with fluid still in the pleural cavity. They cannot afford to take rest till, as Thompson writes, "their blood sedimentation rate becomes normal." Under these conditions many have not developed pulmonary tuberculosis for over five years. Two female patients had one and two deliveries during this period, in spite of medical advice, without untoward effect. One patient who had effusion on one side and subsequently on the other is quite well and working now three years after.

This has been my impression based on clinical experience but unsupported by statistical data. I have come to believe that development of pulmonary tuberculosis subsequent to pleural effusion depends mainly on the "soil" and the resistance of the patient, to less extent on the environment and conditions of life of the patient, and to a negligible extent, if at all, on the rest and sanatorium treatment as held by Drs. Reinhold and Coope.—I am, etc.

Poona City, India.

P. L. DESHMUKH.

### Early Diagnosis of Tuberculous Meningitis

SIR.—A patient was recently admitted for streptomycin treatment of a tuberculous meningitis only after he had been retained one week in another hospital because the chlorides in the cerebrospinal fluid (C.S.F.) had been found to be 0.72% and the diagnosis of tuberculous meningitis, to which other facts pointed, had consequently been rejected. A clear answer seems to be needed to this question: Given a patient with a meningitic picture whose C.S.F. shows a moderate pleocytosis, does a knowledge of the C.S.F. chloride level materially help to distinguish those cases suffering from tuberculous meningitis?

The chloride levels of the first specimen of C.S.F. examined in 52 cases of tuberculous meningitis, 8 cases of benign lymphocytic meningitis, and 10 cases of anterior poliomyelitis (all children) were as follows:

C.S.F. Chlorides	Tuberculous Meningitis Cases	Benign Lymphocytic Meningitis Cases	Acute Poliomyelitis Cases
0.70% or over ..	11	5	10
0.65-0.69% ..	23	3	—
0.60-0.64% ..	18	—	—
Total ..	52	8	10

It is seen that in 1 in 5 cases of tuberculous meningitis the C.S.F. chloride level was not lower than normal, while in nearly half the cases the chloride level fell within the zone of slight reduction (0.65-0.69%) in common with several of the cases of lymphocytic meningitis. In only a third of the cases of tuberculous meningitis was the chloride level substantially reduced

(0.60-0.64%), and in none did it reach the level of 0.59%, which is accepted as diagnostic of the condition. Thus, while a substantial lowering of the C.S.F. chloride level to 0.64% or less would, under the circumstances postulated, favour a diagnosis of tuberculous meningitis, the finding of a normal C.S.F. chloride level should in no wise argue against tuberculous meningitis.

All in all, I suggest that the time devoted by a clinical pathologist to an estimation of the C.S.F. chlorides would be more profitably spent in a search for acid-fast bacilli.—I am, etc.,

Newcastle-upon-Tyne.

DOUGLAS GAIRDNER.

### Reiter's Syndrome

SIR.—As Reiter's syndrome occurs apparently mainly in young adults, I may be permitted to put the following case on record.

On July 23, 1945, an engineer, 55 years of age, consulted me for a purulent urethritis. No gonococci were found in the discharge. On Aug. 3, after 20 g. of sulphathiazole had been given, the discharge had practically ceased, and the smear contained only epithelial cells; but by that time the patient had a bilateral purulent conjunctivitis, again without gonococci in the smears.

On Aug. 10 the eyes were nearly normal, but he then had a painful swelling of an interphalangeal joint of the right foot, which took about 10 days to disappear. On Aug. 15 he started to complain of pain across the shoulders and in the lumbar region, without any obvious pathology, possibly due to a spinal arthritis.

He then went to his home in the North of England, and told me on his return that those pains did not leave him completely for more than two months. In the North a film of his spine was taken in which no changes were seen. He had no diarrhoea either before or during his illness.—I am, etc.,

Harrow Weald, Middlesex.

ALFRED LETICNER.

### Safer Administration of Intravenous Anaesthetics

SIR.—A method for increasing the safety in administering intravenous anaesthetics consists in giving the patient oxygen to inhale for two or three minutes before and during the administration of the intravenous anaesthetic. It is, in my opinion, particularly indicated in patients over 60 or ones who are sub-normal risks.

The rationale of this method is as follows. With most intravenous drugs given for anaesthetic purposes, and particularly with thiopentone, one is struck by the initial and severe depression of respiration that occurs. It is, I think, inevitable that some degree of anoxaemia must ensue, and it is this factor that endangers the patient. In many patients, particularly the elderly, in whom alarming symptoms are most likely to occur with these agents, there is the factor that their lungs have lost their full efficiency and that oxygenation of the blood is neither so quick nor so easy to bring about by the usual methods. If, however, one makes certain that the respiratory system is flooded with a high percentage of oxygen before this period of respiratory depression; then the period will do little harm.

In actual practice I have found that to all appearances my hopes have been justified; the patients have kept an excellent colour and there has been no cause for worry. Occasionally the patient has been told that "he won't have anything put over his face to put him to sleep"; then I assure him that what I am giving him to inhale will not put him to sleep but will help.—I am, etc.,

London, N.W.7.

D. C. CLARK.

### Morphine in a Patent Medicine

SIR.—I should like to comment on the medico-legal note which appeared in your issue of Sept. 27 (p. 511), and referred to the death of a 2-year-old child after taking a patent medicine containing morphine. I gave evidence to the effect that the bottle when full contained just under 1 gr. (65 mg.) of morphine, but according to the *Daily Mail* (June 25) the manager of the firm which manufactures the medicine denied this, alleging that each bottle contained 0.432 gr. (28 mg.). In point of fact the incriminated bottle when full would contain 6 oz. (170 ml.) of fluid and as the concentration of morphine was 0.033% (as stated on

the label) this would work out at just under 1 gr., which is the amount I quoted in my evidence. I have had this checked independently by two chemists. I contacted the manager of the firm and he alleged that the *Daily Mail* had misquoted him. However, he told me that they have now suspended the sale of the preparation.

One further point. Your medico-legal correspondent refers to the Dangerous Drugs Regulations 1937 (S.R.O. 560), which allow the free sale of preparations, etc., containing not more than 2.5% of methylmorphine or ethylmorphine. This is correct, but surely does not apply in this particular case, as the medicine in question actually contained anhydrous morphine, so that the maximum concentration in an inert substance could not contain more than 0.2% in order to be sold freely to the public (*The Chemist and Druggist Year Book*, 1947, p. 339, para e).—I am, etc.,

Manchester.

PAUL B. WOOLLEY.

### Dicoumarol

SIR,—In the annotation (Oct. 25, p. 662) on dicoumarol it is stated: "The prothrombin time is kept at one and a half times the normal value by means of daily doses of 100 to 300 mg. dicoumarol." Earlier it is stated that dicoumarol therapy should be continued for a month at least. Dicoumarol is a very valuable drug, very effective and quite safe if carefully controlled. However, to recommend that 100 mg. to 300 mg. should be given daily for at least a month—even with daily prothrombin estimations as controls—is courting danger.

It would be much safer to recommend 300 mg. a day for two days, then wait for the prothrombin time to lengthen and give no more dicoumarol until the prothrombin time has shortened nearly to normal; this may take ten days. The renewal dose of dicoumarol may be quite small, 25 mg. or 50 mg., and the reaction to the renewal dose will be much greater and more rapid than to the initial doses. There is danger of discrediting a very useful remedy unless dicoumarol is used with great care.—I am, etc.,

Epping, Essex.

FRANK MARSH.

SIR,—The annotation on dicoumarol (Oct. 25, p. 662) prompts me to make certain points which would appear to be of vital importance to those proposing to use that drug.

(1) With levels of dosage of dicoumarol similar to those mentioned by your annotator a sharp rise of the prothrombin time is seen to occur at any time between the 12th and 24th days of therapy. If therapy is discontinued at this time, it is my experience that the prothrombin time not only takes three or four days to fall to safe levels, but may rise alarmingly during those days. It would appear that a cumulative effect of the drug occurs, an effect which constitutes the main danger of dicoumarol, for it is impossible to prognosticate how high the prothrombin time will rise in any given case. It is surprising that more is not made of this cumulative effect in the British or American literature.

(2) Your annotator states that haemorrhagic manifestations may be treated with 50 to 100 mg. of vitamin K intravenously with blood transfusion. A case of my own was under treatment with dicoumarol for post-operative venous thrombosis; 300 mg. were administered on the first day followed by 100 mg. daily. After nine days' treatment the dicoumarol was discontinued, as the prothrombin time had reached 32 seconds. In the next six days one 50-mg. dose of the drug was given to prevent a return to more normal levels of the prothrombin time. This dose should not have been given, as there were red cells in the urine. Six days after the end of the main course, and three days after the 50-mg. dose, the prothrombin time reached 46 seconds and severe haematuria developed. Vitamin K was administered on this day and for the following five days, at a rate of 150 mg. orally per diem. On the first two days of vitamin K therapy 1 pint (568 ml.) of blood was administered. Haematuria remained profuse for two days, diminished on the third day, and was absent from the fourth day. The prothrombin time did not fall until the fifth day, when it fell abruptly to 22 seconds and thereafter to normal levels. This experience strongly suggests that those using dicoumarol should bear in mind that a rapid response to vitamin K and even blood transfusion cannot be counted upon when dicoumarol therapy has produced dangerously high prothrombin times.

(3) Your annotator states that the prothrombin time should be kept at one and a half times normal during dicoumarol therapy. As Allen<sup>1</sup> has shown, it is not adequate to control the therapy by prothrombin times alone. Allen has shown that venous thrombosis is unlikely to occur if the prothrombin percentage is less than 30% of the patient's normal and that 10% of the patient's normal is the critical level for haemorrhagic manifestations. The control should be by prothrombin percentages, which can be obtained from the prothrombin time by the method described by Allen. The margin of safety in dicoumarol therapy is so narrow that any attempt to simplify the control methods is liable to be fraught with grave danger and should be regarded with grave misgivings.—I am, etc.,

Mauchline, Ayrshire.

GAVIN CLELAND.

### Nicotinamide and Blood Sugar

SIR,—I have been interested in the recent article by Dr. J. N. Cumings (Oct. 18, p. 613) on nicotinamide and blood sugar, in which he refers to investigations carried out by me in 1943. It is indeed surprising that such discrepancies in experiment and medical observation can arise, but in Dr. Cumings's work it is certain that many well-established observations on the action of insulin have been overlooked. It is always difficult to adjust curves so that they start from the same level, but in this particular investigation care should have been taken to start from a lower level, for it is well known that the higher the blood sugar the greater the action of insulin. The latter is naturally taken as the deciding factor in the abstracting mechanism of sugar from the blood. The similarity of the curves obtained suggests that the relationship between nicotinic acid amide dosage and its effect was of the same nature in all four subjects. What has not been taken into account is the nature of those factors which so uniformly modified the results in contradistinction to my own.

One may regard the action of nicotinic acid amide by analogy with insulin as the resultant of two opposing forces—viz., the action of the sugar-abstracting mechanism and the glycogenolytic mechanism liberating sugar into the blood. If a level of 105 mg. % is regarded as the uniform fasting level of all individuals tested, then there is after half an hour an abstraction of sugar of 12 mg. %. After one hour there is a rise in the curve by the addition of 5, after one-and-a-half hours of another 5 mg. %, and at the end of two hours sugar is again abstracted from the blood by 14 mg. %. Thus in Cumings's curves, where the fasting level is high, the first sign that the fall of blood sugar is opposed is shown (probably in all four experiments) by a rise in blood sugar after one to one-and-a-half hours, a sign that the raised activity of a surplus of insulin is at once masked and counteracted by a compensatory supply of sugar from the liver into the blood. Otherwise why should there be first an abstraction and then an addition of sugar? For this reason all subjects should have been allowed to settle to a more physiological fasting level on a strict diet before experiments started. It is also suggested to compare the result of smaller doses of injected nicotinic acid (not nicotinic acid amide) and ingested nicotinic acid amide—i.e., 100–300 mg.—to avoid if possible, or to lessen the reaction of, the opposite mechanism. Individual reactions to nicotinic acid vary as they do with insulin, and before larger doses are given smaller ones would ascertain individual reactions to the drug.

The practical value of nicotinic acid in certain cases of elderly diabetes is in my opinion unequivocal, and every case should be first tested as to its response over a period of one to two weeks in varying doses before any other measures are resorted to.—I am, etc.,

Rochdale.

F. J. NEUWAIL.

SIR,—I was very much interested in the article by Dr. J. N. Cumings (Oct. 18, p. 613) and in his negative findings of the effect of nicotinamide (N.A.A.) on the blood-sugar levels in normal controls and in diabetic patients. In spite of these negative findings I feel that there is something in this subject that has not yet been explained, and my clinical experience of two cases in which there has been without doubt some benefit

apels me to suggest that some further research would possibly throw some new light on a treatment which is in some danger of being discredited.

My first case was one of undoubted diabetes mellitus. The patient, a woman aged 67, consulted me on June 9, 1947, because of an intolerable pruritus vulvae which she had had for a fortnight. There was an associated very severe vulvitis. There had been, she said, a sore tongue and mouth a month before. Examination of the urine disclosed a large amount of sugar, and a glucose tolerance test proved this to be due to a diabetic condition (0.18%, 0.3%, 0.33%, 0.28%, 0.28%). I took her to see a consultant, who suggested taking her into hospital for investigation and for the institution of insulin treatment if this was found to be necessary. While waiting for admission to hospital, with a delay of probably a month, the patient was temporarily put on diet. All local treatment of the pruritus and vulvitis had failed to give any relief or effect any improvement either before she was put on diet or for a fortnight afterwards.

I then decided to try the effect of N.A.A. She was given 100 mg. d.s. The urine was carefully watched. No improvement in the pruritus or vulvitis or in the amount of urine sugar was noticed for one week. Then the effect was dramatic. Sugar disappeared from the urine, and the vulval condition completely cleared up in three or four days. There has been no recurrence of either since then. About a month after the commencement of the N.A.A. a florid rash appeared on various parts of the body, but was heaviest on the arms. This was very irritable indeed. She had complained some time previously of tingling of the fingers and a burning sensation in the skin. On the appearance of the rash I stopped the N.A.A. completely for the time being, and it was withheld for one week. No sugar appeared in the urine during this week. When the rash had faded, the dose of N.A.A. was reduced to 50 mg. t.d.s., and she was kept to this dose since with the exception of the last three weeks, when she decided to take none at all to see how she fared without it. No sugar has appeared in the urine during these three weeks. Further, she states that her general health has improved, that she has gained several pounds in weight, and that increase in her carbohydrate intake has not caused any appearance of sugar in her urine or caused any pruritus. When a bed was available in the hospital she refused to be admitted, saying that she was quite better and that, as she had no symptoms and no sugar in the urine, she saw no reason to do so. She has also refused further blood tests for the same reasons.

The second case was that of a man aged 49. Eighteen months ago sugar was found in his urine, and a glucose tolerance test gave perfectly normal findings. Apart from being about 2½ stones (16 kg.) above normal weight he was otherwise normal. He was advised to reduce his weight, and he was put on a strict diet. Sugar was constantly present in the urine on this diet and would only disappear when the carbohydrate intake was minimal. He reduced his weight to normal, but the same appearance of sugar in the urine was constantly noticed.

In June this year I put him on to N.A.A. treatment, 100 mg. t.d.s. This very soon had the effect of causing burning sensations in the skin, very troublesome tingling of the fingers, nervous instability, and, after about five weeks, the onset of the same florid rash noticed in the other case. There was no noticeable diminution of sugar in the urine in this case for the first two weeks of the treatment. A moderate intake of carbohydrate produced no urine sugar subsequently, but a heavy intake produced a small amount. After the first five weeks, the dose of N.A.A. was reduced to 50 mg. t.d.s., and this dose has been kept up ever since. For the last six weeks, no sugar has appeared in the urine no matter what amount of carbohydrate has been taken. The patient states he feels better in health, is more energetic, and there has been some increase in sexual potency. Apart from some tingling of the fingers, there have been no further untoward disturbances as a result of the taking of the N.A.A.

I am aware that only two cases are here described and that no scientific evidence has been adduced, but in spite of these drawbacks I feel that on clinical grounds a case has been made out for further trial and investigation of a line of treatment which, at least to me, appears to have some merit.—I am, etc.,

Leeds

L. GORDON.

### Road Accidents

SIR.—The "Psychological Aspects of Accidents and Accident Prevention," by Kenneth Soddy (Oct. 18, p. 623), recalls to mind a case of a young commercial traveller who used a car for business. He was suffering from a neurosis, one symptom of which was agoraphobia. The open space of a cross-road filled him with terror. He told me that, crossing, he was compelled to look neither to left nor right but to put his foot on the

accelerator and pass his symbolic nightmare as quickly as possible. I saw him twice, when our ways parted owing to the onset of the war. Does he still travel?—I am, etc.,

Ilford, Essex.

R. N. C. SMITH.

### Antihistamine Drugs for Pruritus of Jaundice

SIR.—Re Drs. R. B. Hunter and D. M. Dunlop's letter on this subject (Oct. 4, p. 547), may I point out that "antistin" (N-phenyl-N-benzyl-aminoethyl-imidazoline), now marketed by Ciba in England, was used by Schindler (1946) for seven patients with jaundice of diverse aetiology, with relief of the pruritus in six patients.—I am, etc.,

Leicester

### POINTS FROM LETTERS

#### Foetal Cries

Dr. J. R. EATOUGH (Preston) writes: I wonder if there is any prior record of foetal cries than that contained in *A Second Continuation of Ingulph's History of the Abbey of Croyland*, from which the following extract is taken under the year 1467. "A certain woman, in the county of Huntingdon, who was with child and near the time of her delivery, to her extreme horror, felt the embryo in her womb weeping as it were and uttering a kind of sobbing noise. The same was heard by other women who were surprised in no slight degree thereat."

Dr. ROBERT ANDERSON (Birmingham) writes: Forty years ago I heard an infant cry *in utero*. The head was at or above the brim of a contracted pelvis. I had to introduce my hand into the vagina and was conscious that air was entering alongside of it. Presently I heard a cry but said nothing. When I had delivered it the anaesthetist said, "I heard that baby cry," and the nurse said, "So did I." The baby was all right.

\* Vagitus uterinus was the subject of an article by Mr. I. M. Jackson in this *Journal* in 1943 (Aug. 28, p. 266).—Ed., *B.M.J.*

### NEW MEDICAL FILMS

#### [FROM A CORRESPONDENT]

The Public Relations Division of the Ministry of Health arranged a preview last week of two films intended for medical audiences. Both are worth seeing, and together they unintentionally provided a contrast between the American and British ways of medicine.

The American film, "Prevention of Tuberculosis in Hospitals," opened and closed with a burst of music and had a message. Mass radiography reveals evidence of unsuspected pulmonary tuberculosis in 12 per 1,000 of ordinary Americans. The corresponding figure for Americans attending hospital as out-patients or in-patients is 40 per 1,000. Therefore every hospital should arrange to apply miniature mass radiography to all its patients. This involves a production-line lay-out of the out-patient department, and simplification of the apparatus to the point at which anyone can press the button. Electronic control does everything else except change the spool after every 800 exposures. The patients are numbered. The possible interpretations of the miniature radiograph are numbered. Future action is indicated by a letter code. Numbers and letters are spoken by the radiologist in the general direction of a blonde typist. The camera lingers fondly on admission slips in quintuplicate, filing-cabinets, code numbers, and cameras, and somewhere behind all this glossy machinery is a real live patient.

The British film had no music save that which is heard through a stethoscope. There were no figures except on a sphygmomanometer. And there was one patient, a small girl, who took the centre of the screen all the time. She had a patent ductus arteriosus, which was diagnosed clinically—an old-world touch—and explained diagrammatically by a physician. Then the surgeon took over and ligated the duct. His running commentary was the kind of thing that goes on in every operating theatre. And finally there was the same small girl playing the games she had been unable to play. The message, that early diagnosis is desirable and operation at 7 or 8 gives good results, was spoken, but with so little emphasis that it was easy to remember.

## Obituary

### J. W. GEARY GRANT, F.R.C.S.

Mr. Geary Grant, consulting surgeon to the Royal Infirmary, Cardiff, died at Weymouth on Oct. 23 at the age of 81. He had been in retirement for less than a year, after having been engaged in the active practice of surgery for over fifty years.

John William Geary Grant, son of the late Admiral J. F. Grant, was a student at St. Thomas's Hospital. He qualified in 1890 and took the F.R.C.S. in 1909. He settled in Cardiff in 1913 and soon became well known throughout South Wales. In the first world war he was attached to the Western General Military Hospital at Whitchurch, near Cardiff. After the war he continued in surgical practice and in 1921 was appointed first assistant to the whole-time professorial unit established in Cardiff at that time. He was on the staff of the Cardiff Royal Infirmary for many years, and he was associated with the Treherbert Hospital; the King Edward VII Welsh National Memorial Association; Porth, Bridgend, Caerphilly, and Aberystwyth Cottage Hospitals; and Pentwyn Hospital. He was vice-president of the Section of Surgery at the annual meeting of the B.M.A. in Cardiff in 1928 and contributed a paper on acute necrosis of the pancreas, a subject in which he was particularly interested. He published many other short papers in this and in other journals.

L. C. R. writes: Mr. Geary Grant practised surgery in Cardiff for many years and was much beloved by his colleagues, friends, and patients, for his was a lovable character, invariably courteous, cheerful, and kind. When in 1921, at the instigation of Sir William Osler, whole-time professorial units were established in Cardiff and A. W. Sheen was appointed the first professor of surgery, Geary Grant became the first assistant. He was an inspiring teacher and it would have been difficult to find a more suitable man for the appointment. His mature experience was backed by a keenness for surgery which was undimmed by passing years, and he was an omnivorous reader of surgical papers of all kinds. In consequence there were few surgical questions in which he could not only quote his own experience but that of workers in many and varied clinics. When he was operating, Geary was apt to mutter strange oaths under his breath: they were barely audible and were said with the least invective and entirely without malice, and merely served to endear him all the more to his associates. He came of a Naval ancestry, being the son and grandson of admirals, and it is probable that he would have followed in their wake but for a lame leg which restricted his activities; but he had a somewhat nautical appearance, so that a distinguished stranger at a large dinner, when seated opposite Mr. Grant, once asked his neighbour who the admiral was. Geary Grant's name shines bright in South Wales and perhaps brightest of all in the memories and homes of the miners for whom he did so much, for he was on the staff of various miners' hospitals in different parts of Glamorgan and Monmouth, where the high standard of his work and the kindness and charm of his character will not soon be forgotten.

### JAMES BEATTY, M.D., M.R.C.P.

Dr. James Beatty died at Weston-super-Mare after a short illness on Oct. 16 at the age of 77. He graduated in Dublin in 1895, and afterwards in the London University with honours. Many prizes and distinctions came to him, including the gold medal in anatomy in the London M.B. He took a D.P.H. and the M.R.C.P., and for some years was in the public health service, becoming medical officer of health to Northampton. He entered the R.A.M.C. in the 1914-18 war, and subsequently made his home in Cardiff, where he specialized in dermatology. The department of dermatology at the Cardiff Royal Infirmary was initiated with his appointment as honorary dermatologist in 1923, and he was also dermatologist to the Queen Alexandra Hospital, Weston-super-Mare. He was lecturer in dermatology in the Welsh National School of Medicine, and for a long time also he lectured in pharmacology. Dr. Beatty retired from

the active staff of the Cardiff Royal Infirmary in 1937, returned to full duties when required during the recent war. He was President of the Cardiff Medical Society for 1940 and vice-president of the Section of Dermatology at the Annual Meetings of the B.M.A. in 1928 and 1934.

To many of us who knew Beatty well, he was outstanding as a man of originality, keen perception, and of wide extensive knowledge. Reading was his main relaxation, and had a store of knowledge on such diverse subjects as pharmacology, organic chemistry, ancient history, and the occult, as well as dermatology. For many years Beatty had been increasingly handicapped by failing vision, but had been able to continue his reading and his work under conditions of brilliant illumination, although for some time his vision was restricted to allow him to get about alone. His patience and perseverance in this were remarkable. Despite poor hearing and failing vision Beatty was not one to complain, and preserved an active and cheerful interest in all professional affairs. His colleagues in Cardiff deeply regret the passing of James Beatty, a man of personality and learning and a devoted member of the profession.—J. W. T. T.

Dr. CHARLES KINSMAN RAWES died suddenly after a brief illness at his home on Oct. 8, at the age of 81. A student of Owens College, Manchester, he graduated M.B., Ch.B., in 1911. He was resident medical officer at the Barnes Convalescent Hospital, Cheadle, and later at Weston-super-Mare Dispensary. He was then in general practice at Harlesden, London, N.W. where he remained for forty-four years until he retired in Harrow twelve years ago. He was a keen golfer and was captain of the Wembley Golf Club. A man of retiring disposition, he was much loved by patients and friends alike.—C. I.

ERNEST ARNOLD HODGSON HINDHAUGH, visiting assistant surgeon to Broadgreen Hospital, Liverpool, died on Oct. 5 at the age of 42. He was a student at the London Hospital, qualified M.R.C.S., L.R.C.P. in 1928, graduating M.B., B.S. the following year. He held resident surgical appointments at the London Hospital, the Royal Cancer Hospital, and National Temperance Hospital, and obtained the F.R.C.S. in 1933. Subsequently he held surgical posts at the Royal Portsmouth Hospital; the Royal Hospital, Wolverhampton; and the Road Infirmary, Liverpool. In November, 1939, he became surgical specialist in H.M. hospital ship *Amarapoora* and a distinguished service career until, in 1944, illness led to being invalided out. On his return to Liverpool he became visiting assistant surgeon to Broadgreen Hospital. Despite handicap of failing health, he was in active surgical practice until a few months before his early death. Hindhaugh served a long apprenticeship in surgery and had acquired judgement and skill: He kept meticulous records of all his cases and he was constantly striving to improve on his own standards. Of quiet and retiring disposition, he enjoyed social occasion and liked his fellow men. His hobby was music, and he obtained much pleasure from it. To his wife he brought a deep sense of responsibility and devotion which matched his surgical competence. He will be sadly missed by a wide circle of friends and colleagues, who will wish to extend their sympathy to his sister, Mrs. E. E. Allen, of Dorking, who survives him.—L. F.

Dr. LEONARD WHITE died on Oct. 11. He was a student at Westminster Hospital and qualified in 1906. After a period as house-surgeon, he settled in Mossley, Lancashire, over fifty years ago and soon established himself as a successful practitioner. Though in general practice, his main interest was pathology, and he became pathologist to the District Infirmary, Ashton-under-Lyne. Later he was appointed medical officer of the County Hospital there and remained in charge until 1941. For the last eighteen years he was medical officer of health for Mossley. He was a man of considerable culture and particularly conversant with French literature. He had wonderful memory for what he read, and he maintained interest and did a certain amount of research throughout his years as a practitioner. He equipped himself with a laboratory which was said to be unique for a man in general practice. His technique was so good that it excited the admiration of anyone who was privileged to see him work. For some years he took an interest in local politics, and for a time was a member of the town council. Among his many attainments should be mentioned his versatility as a sportsman. Dr. W.

*Action...where action counts*

'MERTHIOLATE' Brand Sodium Ethyl Mercuri Thiosalicylate exerts its germicidal action without interfering with the normal defences of the body. 'Merthiolate' produces dependable sepsis and is noted for its general clinical applicability. It has measured up to the most critical requirements of the medical profession, and is an antiseptic of choice among many discerning physicians and surgeons.

Among the preparations of 'Merthiolate' now used extensively is the tincture. Tincture 'Merthiolate' is an alcohol-acetone-aqueous solution of 'Merthiolate,' 1:1,000.

Supplied in 4 oz., 16 oz., and 128 oz. bottles.

### Ultra-Violet Therapy

Good equipment gives confidence to the practitioner and patient alike. Lumsden Quartz Sun Lamps have long been noted for their reliability, good performance and compact design.

They are ideal where it is desired to prescribe treatment at home under the physician's guidance.

There is a complete range of these small portable lamps, and delivery can be made from stock.

Full information can be obtained from the LUMSDEN LAMP CO., 251, MILLBURN, ALMONDBANK, PERTH.

## LUMSDEN SUN LAMP

INTRODUCING—

# Spascol<sup>REGD.</sup>

### THERAPY OF SPASMS and of DYSMENORRHOEA

Containing an important new synthetic anti-spasmodic compound, offering outstanding advantages over papaverine in the symptomatic treatment of spasms and dysmenorrhoea.

1. RAPID AND PROLONGED THERAPEUTIC ACTION. (1 tablet taken orally gives prompt relief, lasting from 3 to 6 hours).
2. NON-HABIT FORMING.
3. WELL TOLERATED.
4. EFFECT IS MAINTAINED BY A SMALL DOSE.

had been in failing health for some time and had been unable to work since April. His struggle against ill-health and his calm demeanour and fortitude won him the respect of all who were in contact with him. His passing leaves a gap which will be difficult to fill. His wife, who was French, predeceased him some years ago, and he is survived by four children.—M. L. G.

Dr. CHARLES JOSEPH KIRK died on Oct. 9 after an illness which lasted for two months. He was born in 1884 near Dumbarton, and graduated at Glasgow University in 1913. As a student he took an active part in the production of the university magazine, and many of his poems appeared in that journal. He published a volume of "Clyde Ballads," and wrote several plays, one of which was produced in Darlington several years ago. After qualifying, he settled in Darlington, and during the 1914-18 war carried on single-handed a practice which had required two men to work it. He was honorary secretary of the Darlington Division of the B.M.A. from 1922 to 1925. He was chairman a year later and again in 1945-6, and he represented the Division at the A.R.M. from 1922-5 and again in 1943. In the last war he was a very active and extremely efficient secretary of the Local Medical War Committee, and everyone who came in contact with him knew that his requests would be dealt with quickly. He was also medical officer to an A.R.P. centre. As a colleague he was very loyal, as a friend he gave all he had, and as a doctor he was sympathetic and much loved by his patients. He married Alice Marley in 1917, and she survives him with two sons.—A. M.

Dr. MARY JANET DODDS, formerly a medical missionary at St. Margaret's Hospital, Poona, died at her home in Edinburgh at the age of 77 on Oct. 15. She was a daughter of the late Rev. Dr. James Dodds, of Corstorphine, and sister of a former Under-Secretary of State for Scotland, Sir James Miller Dodds. She was educated at Park School, Glasgow, Edinburgh Ladies' College, and the Edinburgh School of Medicine for Women. She took the Scottish triple qualification in 1895, and was awarded the O.B.E. in 1919 for war work in connexion with the Scottish Churches' Huts at Dregghorn, Colinton. After completing her work in India she was for some years up to 1932 principal of the Deaconess House Training College for Church of Scotland missionaries, and she later became honorary principal of the Women's Missionary College.

Dr. WILFRID WESTWOOD PHILLIPS died suddenly on Oct. 21 at the age of 59. A student of Edinburgh University, he graduated M.B., Ch.B. in 1914, and in the first world war he served as a captain in the R.A.M.C. with the Argyll and Sutherland Highlanders in France and in Mesopotamia. After holding appointments at Leicester Infirmary and at Greenbank Hospital, Darlington, he went into general practice in Twickenham, Middlesex, and Isleworth, where for some years before his retirement, in December, 1945, he acted as district medical officer of health and public vaccinator. Since then he had been living quietly in Yorkshire.

Dr. FRANK RADCLIFFE, of Dedham, Essex, formerly of Oldham, died at the age of 75 on Oct. 19 after a long illness. Dr. Radcliffe graduated M.B., Ch.B. at Owens College, Manchester, in 1894, and proceeded M.D. three years later. As a student he won the Bradley Memorial Scholarship in Clinical Surgery, and after qualifying he acted as prosector and assistant demonstrator in anatomy at Owens College. He had studied midwifery under Tweedie at the Rotunda, and he was a house-physician at the old Manchester Royal Infirmary when it was still in Piccadilly. He acted as a ship surgeon on one of the "Blue Funnel" liners, visiting the East Indies before settling in Oldham. There he was a visiting surgeon on the staff of the Oldham Royal Infirmary until his retirement at the age of 60, and he was also visiting surgeon to the Boundary Park Hospital. He took a prominent part in the local and central activities of the B.M.A. for many years. He was secretary of the Oldham Division for a long period, and he was a member of the Oldham Panel Committee from 1917 until 1932. He had been a member of Council from 1920 to 1934, and he represented the Division at the A.R.M. on nine occasions. He did particularly valuable work on the Insurance Acts Committee, the Public Health Committee, and more recently on the Hospitals Committee. Oldham has long had a reputation for sturdy independence in medical affairs, and Dr. Radcliffe, a hard-headed Lancashire man, ably maintained this tradition. His views on financial matters were always useful, and he was a most efficient Divisional secretary. After his retirement he went to live at Dedham, where he became a member of the Lexden and Winstree Rural District

Council and took part in other local activities. During the war he was interested in A.R.P. work, and was a surgeon to the local St. John Ambulance Brigade. He was a J.P. for the County of Lancaster for many years. He is survived by his widow, who was a daughter of the late Samuel Dronsfield, two sons, both in medical practice, and two daughters.

The Reverend COURTENAY CHARLES WEEKS, who died on Oct. 26 at Pershore Cottage Hospital after a long and trying illness, was a student at University College Hospital and qualified M.R.C.S., L.R.C.P. in 1895. On the outbreak of the 1914-18 war Dr. Weeks was vicar of St. Hilda, Crofton Park, where he had a large congregation. He accepted a commission in the R.A.M.C., and was at the military hospital in Malta during the Gallipoli campaign. On returning to this country Dr. Weeks served as a surgeon at the Royal Herbert Hospital, Woolwich. In September, 1920, he joined the National Temperance League and became one of its most active lecturers. Dr. Weeks also served the temperance movement in many other directions. He gave evidence before the Royal Commission on Licensing in 1929; he convened the centenary celebration of the temperance movement in 1932, and the 20th International Congress on Alcoholism, 1934; and he arranged many medical and educational conferences. Dr. Weeks was an eloquent speaker and a prolific writer. He contributed many articles to different journals and periodicals, and his best-known book was *Alcohol and Human Life*. Since 1940, when Dr. Weeks became the Rector of the Combortons, Worcester-shire, the incumbency of which, owing to the state of his health, he felt it necessary to resign only a fortnight before his death, he had continued his long connexion with the National Temperance League as its honorary medical director and editor.

Dr. ROBERT JAMES LYTLE died on Oct. 26 at the age of 65. The third son of William Lytle, of Cookstown, Northern Ireland, he graduated M.B., B.Ch. at Queen's College, Belfast, in 1906, proceeding M.D. in 1912. After holding resident posts at the Royal Victoria Hospital, Belfast, he came to Portsmouth in 1907 and started private practice in partnership with Dr. Cole Baker. He was for many years honorary physician to the Royal Hospital, the Eye and Ear Hospital, and to the Gosport War Memorial Hospital; he was also visiting physician to St. Mary's Hospital and consulting neurologist to the Ministry of Pensions. He was an active member of the British Medical Association, and was chairman of the Portsmouth Division in 1927-8. In the 1914-18 war he served as a captain in the R.A.M.C. in Malta. In the recent war he carried out his work single-handed and found the time and the energy to hold the onerous position of chairman of the Local Medical War Committee. Here his guidance in the many delicate and difficult problems which arose was of the utmost value. Straightforward and fearless in all he undertook, he had a strong and simple faith, and it was a real source of satisfaction to him when he was made a lay canon of Portsmouth Cathedral. He was a notable and beloved citizen of our city who will be sadly missed in every walk of life. He leaves a widow and four children, and his three sons will carry on his work.—T. B.

Dr. BERNARD RENSHAW BECKIT TRUMAN died suddenly on Oct. 26. A student of Cambridge University and St. Bartholomew's Hospital, he graduated M.B., B.Ch. in 1900 and settled in Nottingham, where his father and his grandfather had practised. He was in charge of the infant welfare clinics in Nottingham, was honorary physician to the Nottingham Children's Hospital, and was in active practice for over forty years. He was a former president of the Nottingham Medico-Chirurgical Society, and on his retirement about two years ago he was appointed consulting physician to the Children's Hospital.

Dr. J. B. Miller, Bishopbriggs, writes: The death of Dr. John Goff recalls to older members the names of Bruce and John Goff, father and son, who for over sixty years carried on an extensive practice, based on the village of Bothwell on the banks of the Clyde in Lanarkshire. Bruce Goff occupied a prominent position in medical circles in the West of Scotland and in Association activities. He was a member of Council for twenty-four years (1884-1908), and was also President of the Faculty of Physicians and Surgeons of Glasgow, a very rare honour for a country practitioner. John Goff was, in succession, chairman of his Division, president of the Branch, and chairman of the Scottish Committee, while he was a member of Council for four years (1917-21), relinquishing office on his removal to Surrey. He always had the deepest interest in medico-political affairs, and carried out his various duties in a conscientious if unobtrusive manner.

## Medical Notes in Parliament

### Medical Practitioners and Pharmacists Bill

In the House of Lords on Oct. 28, Lord HENDERSON introduced on behalf of the Government the Medical Practitioners and Pharmacists Bill, and it was formally read a first time. Lord Henderson said the Bill was to make provision for the registration as medical practitioners or as pharmacists of certain persons having qualifications other than the United Kingdom qualifications required by the Medical Acts and the Pharmacy Acts and to repeal certain provisions as to pharmacists. This Bill was given a first reading in the House of Commons on Aug. 4 and was the subject of a leading article in our issue of Aug. 16 (p. 258).

### National Assistance Bill

The National Assistance Bill was presented in the House of Commons on Oct. 30 by Mr. BEVAN and was read a first time. The Bill is discussed in a leading article elsewhere in this issue (p. 736).

### Criminal Justice Bill

On Oct. 31 Mr. CHURCHILL presented the Criminal Justice Bill to "abolish penal servitude, hard labour, prison divisions, and sentence of whipping; to amend the law relating to the probation of offenders, and otherwise to reform existing methods and provide new methods of dealing with offenders and persons liable to imprisonment; to amend the law relating to the proceedings of criminal courts, including the law relating to evidence before such courts; to regulate the management of prisons and other institutions, and the treatment of offenders and other persons committed to custody; to re-enact certain enactments relating to the matters aforesaid; and for purposes connected therewith."

The Bill received a first reading.

**Milk for Infants.**—Mr. STRACHEY said on Oct. 27 that the milk allowance for babies up to 12 months old had not been reduced. The reduction in the allowance to children between 1 and 5 years of age was made in preference to reducing other priority or non-priority allowances on the recommendations of the medical and nutritional advisers of the Ministry.

**Canine Hysteria.**—Mr. RHYS DAVIES on Oct. 28 called the attention of the Home Secretary to two reviews of feeding experiments on dogs designed to produce symptoms of canine hysteria. He asked the Minister in future to refuse to sanction the duplication of such experiments. Mr. EDE assumed that Mr. Rhys Davies referred to experiments regarding the effect on the practice, which Mr. Ede said was now generally adopted, of treating flour with agene. Mr. Ede said he would not feel justified in disallowing these experiments on the ground that parallel ones were in progress.

**Shoreditch Hospital.**—On Oct. 30 Mr. ERNEST THURTELL asked the Minister of Health if he had considered the memorandum signed by 33 medical practitioners in Shoreditch and neighbourhood regarding the threatened closing of the in-patient wards of St. Leonard's Hospital, Shoreditch, and asking that he should intervene and cause a public inquiry to take place before action to close the hospital was taken. Mr. BEVAN said he had considered this representation. The London County Council had appealed to him under the Nurses Registration Act, 1919, against the decision of the General Nursing Council to withdraw recognition from this hospital as a training school for nurses. He was arranging for the appeal to be heard shortly.

**Mass Radiography.**—Mr. SIDNEY SHEPARD inquired on Oct. 30 what progress was being made in the provision of mass radiography sets. Mr. BEVAN replied that there were 23 sets operating in England and Wales. Arrangements were in progress for starting 14 more, and further expansion was planned as apparatus came forward. Up to the end of June some 1,669,000 persons had been examined.

**Groundnuts Scheme.**—Mr. STRACHEY states that the establishment of health services for the East African groundnut scheme is well advanced. Thirty-four appointments have been made in the medical department. In addition African medical auxiliaries and nursing staff are being trained. Temporary hospital accommodation is available.

**Rationed Calories.**—Dr. Summerskill calculates, that the caloric value of the rations, including points rationed foods, of the ordinary adult in Great Britain is about 1,530 calories a day.

## Medico-Legal

### RESPONSIBILITY FOR CRUELTY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Cruelty as a matrimonial offence has never been defined by courts but has always been strictly interpreted. Roughly speaking a party who petitions the court for divorce on the ground of cruelty by the other party to the marriage must prove a course of conduct which endangers the life or health of the petitioner or causes reasonable apprehension of danger. Moreover, conduct must be deliberate. In *Astle v. Astle* (1939) the court rejected a petition because the wife had been insane during the period in question. Recently it rejected another on the ground that the wife had been irresponsible though not actually insane. The parties were married in 1932, the husband being a regular Army officer. In India in 1940 the wife became extremely ill. In her early life she had had a double mastoid operation and she had ever afterwards suffered from sinus trouble. She had two serious operations during her married life and lost her ovaries, and later she developed coronary thrombosis and suffered from myocarditis. One of the results was constant severe insomnia. A most difficult situation developed for the husband, for she became physically dependent on him to an extreme degree. She required him to read her to sleep at night and to dress her and bathe her, and to be in constant attendance on her whenever he was not on duty. He and his work began to suffer from worry and lack of sleep. He lost his concentration and efficiency. In 1944 he took her back to England and lodged her in her mother's house. From India he wrote her kindly and affectionate letters until 1946, but then he declared that the strain of living with her was impossible to bear and that he would not live with her again.

Mr. Justice Finckmore said that the case had caused him great difficulty and his mind had fluctuated during the hearing. The dilemma was complete: either he had to refuse relief to the husband although his married life had been desperately difficult or he had to declare guilty of matrimonial cruelty a wife who had during the material years been extremely ill. Counsel for the husband argued that the wife must be taken to have appreciated the effect her demands would have on him and to have intended their natural consequences—that his health would break down. He referred to the rules in *M'Naghten's Case* which lay down that to escape responsibility on the ground of mental disease a defendant must show either that he did not know what he was doing or that he did not know that it was wrong. The judge thought that this was a rather unreal position to apply in a case of this kind. The wife had not been accused of crime, and there was no question of her being insane and thinking a thing was right when it was obviously criminally wrong. On the other hand, the husband accused her of deliberately, maliciously, and sadistically stopping him from sleeping, and the judge thought that the case stood or fell on whether the wife's conduct was what is commonly called nagging, which when continued for a long period has been held to constitute cruelty. He doubted whether she had thought very much about her husband. She was very sick and in considerable pain. If a wife were to say, "I can't sleep, so you shan't," it might be cruelty, but the judge did not think that she had done this deliberately, out of spite, set out to hurt him or prevent him from sleeping.

He did not find the deliberateness, or malignity, or intention which the law requires to constitute cruelty. Unfortunately many marriages one party developed an incurable disease and demanded constant attention of all sorts, but no one would dream of saying that that involved cruelty. It was part of the marriage service that the parties undertook to cherish each other in sickness or in health. This marriage became impossible not because the wife was cruel but because she was desperately ill and getting worse. He therefore would not grant the divorce.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

The following medical degrees were conferred on Oct. 18:

M.D.—C. W. A. Searle.  
M.B., B.Chir.—A. S. Fairbairn, \*A. P. C. Bacon, \*H. B. Barlow, \*D. M. Evans, \*L. C. K. Mackenzie, \*J. S. W. Whitehead, \*E. T. Roberts, \*M. H. D. Veale, \*P. E. Hughesdon, \*W. Spector, \*C. F. Hingston, \*R. H. L. Wolfsohn, \*A. J. W. Woodroffe, I. B. Smith, J. L. Harris.  
\*M.B.—N. C. London.

\*By proxy.

### UNIVERSITY OF ABERDEEN

John Craig, M.B., Ch.B. Aberd., F.R.C.P.Ed., M.R.C.O.G., lecturer in diseases of children, has been appointed to the new Chair of Child Health in the University.

### UNIVERSITY OF EDINBURGH

Norman McOmish Dott, M.B., Ch.B., F.R.C.S.Ed., Director of the Neurological and Neurosurgical Brain Injuries Unit at Bangour Hospital, Uphall, West Lothian, has been appointed first holder of the Forbes Chair of Neurological Surgery in the University.

### UNIVERSITY OF GLASGOW

At a Ceremony of Graduation, held on Nov. 1, the following degrees were conferred:

M.D.—P. Macarthur (with commendation), F. J. Hebbert, J. E. Tillotson.  
The degree of Bachelor of Law was conferred on George Buchanan, L.R.C.P.&S.Ed.

### UNIVERSITY OF LONDON

Dr. Hermann Mannheim will deliver a course of eight weekly lectures on "The Philosophy and Psychology of Punishment," at the Institute for the Scientific Treatment of Delinquency, 8, Bourdon Street, Davies Street, W., on Mondays, at 6.30 p.m., beginning on Jan. 12, 1948. He will develop his theme from punishment in primitive societies, punishment by parents and teachers and by Church and State, up to a concluding lecture on punishment in the international sphere, with special reference to war crimes and the Nuremberg trials. He will also discuss the aims and the effect of punishment, and the obstacles in the way of establishing a reasonable penal system.

Prof. Henry Barcroft, M.D., has been appointed to the University Chair of Physiology tenable at St. Thomas's Hospital Medical School from Jan. 1, 1948.

Victor Wilkinson Dix, F.R.C.S., has been appointed to the University Chair of Surgery tenable at London Hospital Medical College from Oct. 1.

Thomas Duncan Day, M.D., has been appointed to the University Readership in Pathology tenable at St. Thomas's Hospital Medical School from Oct. 1.

Thomas Russell Cumming Fraser, M.D., M.R.C.P., D.P.M., has been appointed to the University Readership in Medicine tenable at the British Postgraduate Medical School from Aug. 1, 1947.

C. J. O. R. Morris, M.Sc., Ph.D., has been appointed to the University Readership in Chemical Pathology tenable at London Hospital Medical College from Oct. 1.

The degree of D.Sc. has been conferred on Claude Rimington, Ph.D., professor of chemical pathology at University College Hospital Medical School.

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN CLINICAL PATHOLOGY.—B. M. Bloomberg, M. J. G. Furnell, B. Godwin, Elizabeth Himmelfoch, G. B. Leyton, A. G. E. Pearce, J. T. Prendiville, V. A. Vanikar.

EXTERNAL DIPLOMA IN CLINICAL PATHOLOGY.—H. B. Stein.

### UNIVERSITY OF SHEFFIELD

The following appointments were made at a meeting of the University Council held on Oct. 17: *Honorary Lecturers in Pathology*, J. L. Edwards, M.B., Ch.B., M.R.C.P., LL.B., and L. C. D. Hermitte, M.B., Ch.B. *Part-time Lecturer in Medicine to Dental Students*, R. T. Gaunt, M.Sc., M.B., Ch.B., M.R.C.P. *Assistant Lecturer in Pathology*, H. J. Whiteley, M.B., Ch.B.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The annual meeting of Fellows and Members will be held at the College (Lincoln's Inn Fields, London, W.C.) on Wednesday, Nov. 12, at 5.30 p.m., when a report from the Council will be presented.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At the annual meeting of the College held on Oct. 29 the following officers were elected for the ensuing year: *President*, Mr. Frank E. Jardine; *Vice-President*, Mr. James M. Graham; *Secretary and Treasurer*, Mr. K. Paterson Brown; *Representative on General Medical Council*, Sir Henry Wade; *Conservator of Museum*,

Mr. James N. J. Hartley; *Convener of Museum Committee*, Mr. W. Quarry Wood; *Librarian*, Dr. Douglas Guthrie.

The following candidates, having passed the requisite examinations, were admitted Fellows:

J. Aitken, H. M. Bennett, S. M. Bactor, Y. G. Bodhe, E. S. Brawn, J. E. S. Carmichael, Florence Cavanagh, D. H. Clark, J. C. Comline, W. T. Cumming, J. B. Cuthbert, N. M. B. Dean, D. Dencer, M. D. Desai, G. de L. Fenwick, W. J. Fraser, D. Ghose, I. L. Gregory, A. P. Guttman, J. A. V. Hamilton, H. El S. Higazi, R. M. Hugo, J. Hustoo, G. C. W. James, J. M. Jones, V. A. F. Martin, E. Millington, J. C. G. Moore, G. Murdoch, A. M. Murray, M. P. McCormack, C. G. G. Mackay, F. D. Mackenzie, D. L. Poddar, E. W. Price, Agnes R. Russell, W. H. Scrase, E. Seideoman, N. C. Sen, N. C. Shah, H. V. Ol-M. Shaibany, K. J. Sheth, D. W. Short, F. MacN. Smith, C. E. E. Stevens, F. V. Stonham, J. W. M. Sutherland, A. F. Torrie, S. L. Townsend, H. M. Urquhart, C. H. Vipond, R. G. M. Wedderburn, V. H. Wheble, J. S. Young.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the annual meeting of the College, held on Oct. 18, the following officers, etc., were elected: *President*, Dr. Bethel Solomons; *Vice-President*, Dr. E. A. Keelan; *Treasurer*, Prof. G. Bewley; *Registrar*, Dr. T. P. C. Kirkpatrick; *Representative on General Medical Council*, Prof. T. Gillman Moorhead; *Representative on Medical Registration Council*, Prof. J. W. Bigger.

## The Services

The King of Norway has conferred the Knight Grand Cross of the Order of St. Olav upon Air Marshal Sir Harold E. Whittingham, K.C.B., K.B.E., R.A.F. (Retired).

Major (Honorary Lieutenant-Colonel) J. G. McCrie, O.B.E., and Captains (Honorary Majors) W. A. Liston, M.C., and G. K. Thornton, R.A.M.C., have been awarded the Efficiency Decoration of the Territorial Army.

Captain B. G. Duggan, Lieutenant (now Temporary Major) J. J. Wiese, and Lieutenant (now Captain) H. A. Wood, R.A.M.C., have been awarded the Long Service and Good Conduct Medal (Military), without Gratuity.

Captain (Honorary Major) J. Kerr and Lieutenant (Honorary Captain) L. C. J. Coker, R.A.M.C., have been awarded the Efficiency Medal (Territorial).

### DEATHS IN THE SERVICES

Surgeon Rear-Admiral Sir GEORGE WELCH died on Oct. 26 at the age of 90. Born on Sept. 13, 1858, he entered the service in 1884 and was promoted surgeon-general in 1915. He was surgeon of the *Royalist* in the Niger expedition in 1886, and staff-surgeon of the *Tyne* during the Cretan troubles in 1896-7, and was specially promoted to fleet-surgeon in 1899 for conspicuous professional merit. Among other appointments he held were those of assistant to the medical director-general, 1899-1906, and instructor in Naval hygiene to surgeons on entry at Haslar, 1906-10. He was a member of the Commission to inquire into tuberculosis in the Navy in 1911; deputy director-general of the Medical Department of the Navy, November, 1912-16; and a member of the Committee on Vision of Naval Officers, 1914. He was awarded the C.B. in 1917 and created K.C.M.G. two years later. He was placed on the retired list in 1918 after thirty-four years' service, for the last two years of which he was P.M.O., R.N. Hospital, Haslar.

## EPIDEMIOLOGICAL NOTES

### Poliomyelitis

Notifications of poliomyelitis in England and Wales in the week ending Oct. 25 showed a further small reduction on those of the previous week, 251 (276), but those of poliomyelitis showed a rise, 29 (12). The trend of incidence of poliomyelitis has not been very consistent throughout. It seems likely that there are considerable differences in the meaning attached to this term by different doctors.

Provisional figures of registrations of deaths from poliomyelitis and poliomyelitis supplied by the Registrar-General are as follows: July, 74; August, 206; September, 160. It is, of course, impossible to relate these directly to notifications because of the varying duration of illness and possible delay in the registration of a death, but notifications which relate to roughly the same periods were:

	Poliomyelitis	Poliomyelitis
July .. .. .	668	75
August (5 weeks) .. .. .	2,900	235
September .. .. .	2,246	143
	5,814	453

These figures suggest a case fatality rate of the order of 7%. Preliminary analysis of deaths by age suggests that the increase

in the fatality of the disease in older age groups which has been reported in other countries has also been a feature of the epidemic here.

It is hoped that more information on this and other matters will be derived from the survey of hospital cases now being undertaken by the Ministry of Health. In our last issue (Nov. 1, p. 698) some details were given of the two large-scale investigations of this year's prevalence of poliomyelitis which are now in progress. Once the questionnaires have been drawn up and completed their final analysis will be undertaken by the Institute of Social Medicine and the Bureau of Health and Sickness Records.

In the week ending Oct. 18 notifications of poliomyelitis declined for the sixth consecutive week, and the largest centres of infection during the week were Lancashire 46 (Manchester C.B. 11, Liverpool C.B. 6); London 24; Yorkshire West Riding 18; Middlesex 27 (Ealing M.B. 6, Harrow U.D. 6); Warwickshire 20; Hertfordshire 11; Kent 10; Durham 8 (Sunderland C.B. 5); Essex 8; and Glamorganshire 8.

### Cholera in Egypt

Official reports still list 300 to 400 deaths from cholera and 800 or more new cases daily. The true figures are probably higher because of the failure to notify cases. Penalties for non-notification have recently been increased, and it is officially stated that the whole Delta is affected except Cairo and Alexandria. The disease has also continued to gain ground in Upper Egypt.

Daily bulletins were not issued over the three-day Bairam holiday, but the consolidated figures over this week-end showed that there had been 2,672 cases and 1,360 deaths. The two areas most affected are still Dakahlia and Gharbieh. More cases have also been reported recently from Behera. According to a report from Reuter the Egyptian Government is to buy and destroy the new date crop from Koerin, where the present epidemic is thought to have originated.

Stringent precautions have been taken to prevent the possible spread of cholera to the British Forces in Egypt. All native villages and restaurants have been placed out of bounds; anti-fly measures have been intensified; and a more careful watch than usual is being kept upon the food and drink supplied to the troops. All officers and men likely to come in contact with infected material or to pass through infected areas have been inoculated, though it has not yet been thought necessary to introduce large-scale inoculation.

### Discussion of Table

In *England and Wales* further increases were recorded in the incidence of measles 158, acute pneumonia 128, and scarlet fever 36, while further decreases were reported in the number of notifications of acute poliomyelitis 62, whooping-cough 34, and dysentery 21.

A rise in the incidence of measles was general; the largest increase was in Monmouthshire 48. The rise in the notifications of acute pneumonia was most marked in two regions, London and the South-east, with an increase of 45, and the west Midland counties with a rise of 49. The largest variations in the local returns of scarlet fever were an increase in London 32 and a decrease in Staffordshire 23.

The only fluctuation of any size in the trends of whooping-cough was a fall in Lancashire 35. The returns of diphtheria showed little variation from those of the preceding week; the greatest change was a decrease of 9 in Warwickshire. The only return of dysentery of any size was in Lancashire 11.

In *Scotland* infectious diseases were less prevalent during the week, and the decreases in incidence included: scarlet fever 33, acute poliomyelitis 21, whooping-cough 12, and measles 11. The only appreciable rise was in the notifications of acute primary pneumonia 20. The largest returns for poliomyelitis were those of the cities of Edinburgh 8 and Glasgow 8. The increase in cases of acute primary pneumonia was confined to Glasgow, where the notifications rose from 96 to 119.

In *Eire* increases were recorded in the notifications of measles 41, scarlet fever 21, diarrhoea and enteritis 21, and whooping-cough 9. The rises in the incidence of measles and diarrhoea and enteritis were due to the experience of Dublin C.B., with increases of 31 and 19 respectively.

In *Northern Ireland* only small changes were recorded in the trends of infectious diseases. The notifications of poliomyelitis were 4 fewer than in the preceding week.

### Week Ending October 25

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,452, whooping-cough 1,003, diphtheria 238, measles 1,981, acute pneumonia 482, cerebrospinal fever 34, acute poliomyelitis 251, acute poliomyelitis 29, dysentery 340, paratyphoid 3, and typhoid 4.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 18.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

faster,

faster, faster!

THE LONG hind legs of the hare which make its speed possible, especially when running uphill, are an excellent example of the adaptation to environment upon which an animal's survival depends. Man also adapts himself to environment, but, under certain circumstances his adaptation may not be sufficiently rapid. The resulting maladjustment may be revealed by deficiency conditions which must be corrected by medicinal means as, for example, treatment with B.D.H. Sex Hormone Products.

In conditions arising from corpus luteum deficiency Progestin B.D.H. and Ethisterone B.D.H. are the products of choice.

## The Successful Treatment of

### FIBROSITIS

and certain cases of

### RHEUMATISM

with

### NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: 3%, 1% and 2% Solutions.  
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.0032 gm. epinephrine and 0.0032 gm. capryl hydrocupreintoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

PHARMACEUTICAL MANUFACTURING CO. LTD.  
THE LABORATORIES, CHELTENHAM, GLOS.

## SOLUBLE THIOPENTONE

SOLUBLE THIOPENTONE-BOOTS is an intravenous anæsthetic of proved value. As a basal anæsthetic prior to general anæsthesia, it has been used extensively and has given uniformly good results over a considerable period under widely varying conditions and dosage.

Soluble Thiopentone has been used successfully and is recommended as a total anæsthetic for short minor operations, and also for long operations which do not demand considerable muscular relaxation.

Soluble Thiopentone is a mixture of 100 parts by weight of the mono-sodium derivative of 5-ethyl-5-(1-methylbutyl)-thiobarbituric acid, and 6 parts by weight of exsiccated sodium carbonate as laid down in the B.P. Addendum VII. Available in Boxes of 6 and 25 ampoules of 0.5 gm. and 1.0 gm.

## *A Delicious, Concentrated, Vitamin Food of the Highest Quality*

*A Product of the Ovaltine Research Laboratories*

TO the physician requiring a product which incorporates important vitamins in a form acceptable to every patient, "Vimaltol" presents special advantages.

"Vimaltol" is made from specially prepared malt extract of high protein content; yeast—one of the richest sources of vitamin B<sub>1</sub>—and Halibut Liver Oil, an important source of vitamins A and D. It is also fortified with additional vitamins and mineral salts, and is deliciously flavoured with orange juice.

"Vimaltol" is standardized to contain in each fluid ounce: 648 international units of vitamin A and 1390 of vitamin D; also 0.3 milligrammes of vitamin B<sub>1</sub>, 4 of Niacin (P.P. vitamin) and 4.8 of Iron, in a readily assimilable form.

"Vimaltol" is thus an important aid in the treatment of the many abnormal conditions resulting from the deficiency of one or more of the essential vitamins in the average everyday dietary.

The routine use of "Vimaltol" helps normal development of the growing organism and the maintenance of correct metabolism, while raising the general resistance against infection.

"Vimaltol" has thus a very wide application in general practice for patients of all ages. It can be prescribed with advantage at all seasons.

*A liberal supply for clinical trial  
sent free on request.*

## CHLOROFORM

DUNCAN

For one hundred years Duncan, Flockhart & Co. have been making chloroform. They produced the chloroform which Prof. James Young Simpson first introduced into medicine in 1847. On account of its unsurpassed purity and stability, CHLOROFORM—Duncan, like the Company's other anaesthetics, has won the confidence of anaesthetists in all parts of the world.

## An improved Diphtheria Prophylactic

**D**IPHThERIA Toxoid, Aluminium Phosphate Precipitated (P.T.A.P.) is a new diphtheria prophylactic of remarkably high potency developed in the Wright-Fleming Institute of Microbiology (late Inoculation Department), St. Mary's Hospital, London.

"P.T.A.P." is prepared from highly purified diphtheria toxoid using aluminium phosphate as precipitant and mineral carrier and possesses the following advantages:—

1. Only highly purified toxoid—from a peptone-free medium—is used.
2. The mineral carrier is pure aluminium phosphate only.
3. The optimal amount of mineral carrier for human prophylaxis is employed.
4. The preparation of "P.T.A.P." may be regularly and readily reproduced.
5. The use of highly purified toxoid reduces to a minimum the risk of specific reactions.
6. The carrier, itself, has been shown to be quite innocuous even when excessive amounts are used.

Supplied in sets of 2 immunizing doses, and in vials of 10 c.c.

## Medical News

### Report on Nursing

Mr. Aneurin Bevan, Minister of Health, addressing nurses at the Middlesex Hospital on Oct. 24, described the Report (Sept. 13, p. 426) of the Working Party on the recruitment and training of nurses as the "most stimulating and challenging document yet produced on nursing." He suggested the following plan for immediate action: (1) Review of factors likely to contribute to wastage among nursing recruits; (2) relieving nurses of domestic work; (3) part-time nursing. Some big hospitals with no shortage of nurses still used them for domestic work, such as sweeping wards, he continued. This was not fair to other hospitals faced with the terrible prospect of having to close wards. We could no longer afford to waste the skill of nurses with domestic responsibilities who were willing to work on a part-time basis. But, as they had learned in the war, hours and conditions for married women must be made to fit their convenience, instead of their having to fit the convenience of the hospital. Having promised to consider the views of the nursing profession before any final decisions were taken on the Working Party's recommendations, he had sent the Report to all the major bodies concerned with nursing and asked for their views. Mr. Bevan gave the following figures of hospital staffing: Over 12,600 nursing staff, including 1,740 midwives, have so far responded to the appeal for part-time service. As a result, hospitals in different parts of the country have been able to reopen wards. There are now nearly 100,000 full-time and 18,000 part-time domestic workers in hospitals—an increase of some thousands since 1946. They include nearly 3,000 European volunteer workers.

### Emergency Bed Service

The telephone number of the Emergency Bed Service has been changed. Instead of Monarch 8515 it will in future be Monarch 3000.

### Orange-juice Jelly

Stocks of orange-juice jelly are coming to an end, and it therefore cannot be supplied in schools after Nov. 8. A Ministry of Education memorandum to education authorities draws attention to the value of salads as an alternative source of vitamin C.

### The Surgical Congress

Prof. Grey Turner informs us that Prof. Tomas Zerolo, representative of the Consejo General de los Colegios Medicos of Spain, has written expressing gratitude for the reception accorded to himself and his colleagues at the 12th Congress of the International Society of Surgery, held in London in September. "The Congress has not only been a great success scientifically," he wrote, "but it has been the means of bringing together surgeons from all over the world, in mutual understanding of friendliness and true comradeship for the good of humanity."

### Radiologist in Turkey

Dr. H. Gálami Hodgson, Director of the Diagnostic X-Ray Department at the Middlesex Hospital, London, has gone to Turkey for a three weeks' lecture tour on behalf of the British Council. His subjects will include: mass miniature radiography of the lungs; the planning of a modern diagnostic x-ray department; and lectures on the radiology of the temporal bone, the upper gastro-intestinal tract, and the accessory nasal sinuses.

### South-West Metropolitan Regional Board Psychiatric Advisory Group

At a recent meeting of psychiatrists of the South-West Metropolitan Region it was resolved to form a psychiatric advisory group to take the initiative in forwarding to the regional board such proposals as seem to it desirable for the development of the mental health services in the region, and to be available for consultation with the subcommittee on matters of psychiatric importance. Membership of the group is open to all psychiatrists in the region and all who are interested are asked to communicate with Dr. T. P. Rees, Warlingham Park Hospital, Warlingham, Surrey.

### Anaesthetist Visits Argentina

Dr. W. W. Mushin, Director of the Department of Anaesthetics at the Royal Infirmary, Cardiff, attended the Congress of Anaesthesiology in Buenos Aires, on Oct. 20-26 at the invitation of the Argentine Association of Anaesthesiology and under arrangements made by the British Council. He read a paper on "Recent Anaesthetic Research."

### International Orthopaedic Course

The Second International Course for the Emergencies of Medicine and Surgery met in Lisbon and Oporto from Oct. 1 to 15. It was organized by the Civil Hospitals in Lisbon under the aegis of the Portuguese Ministry of the Interior. The British representatives who spoke were Sir Archibald MacIndoe (on middle facial injuries and burns); Mr. H. A. Britain (on the acutely prolapsed intervertebral disk and compound fractures of the femur); Prof. R. G. Pulvertaft (on tendon injuries in the hand); and Mr. H. Osmond Clarke (on compound fractures and rehabilitation).

### Willis

Dr. Alwyn Hewett Bradley, of Leicester, who died on March 9, left £36,019. Colonel Edgar Thomas Inkson, V.C., late R.A.M.C., of Chichester, who won his V.C. in 1900 "for conspicuous bravery in carrying an officer to safety under heavy fire," left £7,257.

## COMING EVENTS

### Franco-Anglo-American Medical Society

The next quarterly meeting of the British Section of the Franco-Anglo-American Medical Society will be held at 11, Chandos Street, London, W., on Tuesday, Nov. 11, at 2.30 p.m., with Lord Horder in the chair.

### Tuberculosis Association

A meeting of the Tuberculosis Association will be held at the Assembly Hall, Royal Empire Society, Craven Street, London, W.C., on Friday, Nov. 14, at 3 p.m., when Dr. F. R. G. Heaf will deliver the presidential address on "Accommodation for the Tuberculous" and Mr. Hamilton Bailey and Dr. Suzette Gauvain will read papers on "Tuberculous Glands of the Neck."

### Association of Allergists

A meeting to discuss the formation of an Association of Allergists will be held in the lecture theatre of the Nuffield Laboratory of Ophthalmology, the Oxford Eye Hospital, on Saturday, Nov. 15 at 2.30 p.m. All those interested in the study of allergy are invited to attend.

### Harben Lectures

We are informed by the Royal Institute of Public Health and Hygiene that the dates of the Harben Lectures, announced in this column on Oct. 25 (p. 676), have been changed. Prof. E. D. Adrian, O.M., M.D., F.R.S., F.R.C.P., will deliver them at the Institute (28, Portland Place, London, W.) on Monday, Tuesday, and Wednesday, Dec. 15, 16, and 17, at 3 p.m. each day, *one week later than originally arranged.*

### Hunterian Society

The 1947-8 session of the Hunterian Society opened on Oct. 29 when Mr. Alex. E. Roche delivered his presidential address on "The Interpretation of Urological Symptoms." Other meetings have been arranged as follows: Monday, Nov. 17, 8.30 p.m., at Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, London, E.C. Motion, "That Our Present Diet is Undermining the Health of the Nation," to be proposed by Drs. Franklin Bicknell and Kenneth McFadyean and opposed by Sir Jack Drummond, D.Sc., F.R.S., and Magnus Pyke, Ph.D. Monday, Dec. 15, 7 for 7.30 p.m., dinner-meeting at Talbot Restaurant, London Wall, E.C. Discussion on "Menstrual Disorders in Relation to General Medicine," to be opened by Mr. Aleck Bourne, Dr. Edward Sharp, and Mr. John Howkins. Monday, Jan. 19, 1948, 8.30 p.m., at the Mansion House, London, E.C. Hunterian Lecture by Prof. J. Cid Dos Santos (Lisbon), "Recent Improvements in the Diagnosis and Treatment of Vascular Obstruction." Thursday, Feb. 12, at Grosvenor House, Park Lane, London, W. Annual dinner. Monday, Feb. 23, 8.30 p.m., at the Mansion House, London, E.C. Hunterian Oration by Dr. W. S. C. Copeman, "Rheumatism in the Time of John Hunter." Monday, March 15, 7 for 7.30 p.m., dinner-meeting at Talbot Restaurant. Discussion on "Neuritis," to be opened by Dr. Philip Ellman, Dr. Aldren Turner, Mr. Dudley Buxton, and Dr. F. S. Cooksey. Monday, April 19, 7 for 7.30 p.m., annual general (dinner) meeting at Talbot Restaurant. Address by Mr. A. L. Bacharach, "Laboratory Animals—Their Uses and Abuses."

### Pharmaceutical Society of Great Britain

On Thursday, Nov. 13, at 7.30 p.m., the Hanbury Memorial Medal of the Pharmaceutical Society of Great Britain (17, Bloomsbury Square, London, W.C.) will be presented to Hans Flück, D.Sc., professor of pharmacology in the Faculty of Pharmacy of the Swiss Federal Technical Institute, Zurich. Prof. Flück will then deliver a lecture on "Chemical and Biological Aspects of the Conservation of Vegetable Drugs."

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tuesday, Nov. 11, 5 p.m. Lloyd-Roberts Lecture by the Hon. Harold Nicolson: The Health of Authors.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—Thursday, Nov. 13, 5 p.m. Bradshaw Lecture by Sir Cecil Wakeley: Vogue and Fashion in Abdominal Surgery.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, W.—Friday, Nov. 14, 5 p.m. William Blair-Bell Memorial Lecture by Dr. D. J. MacRae: Heart Disease in Pregnancy.

## ROYAL SOCIETY OF MEDICINE

*Section of Psychiatry.*—Tuesday, Nov. 11, 5 p.m. Paper by Dr. Fraser-Steele: The Assessment of Prognosis in Psychiatry.

*Section of Physical Medicine.*—Wednesday, Nov. 12, 4.30 p.m. Discussion: Brachial Neuralgia. Openers: Dr. W. Russell Brain and Mr. D. W. C. Northfield.

*Section of Proctology.*—Wednesday, Nov. 12, 5 p.m. Presidential Address by Mr. A. Dickson Wright: Total Colectomy.

*Section of Ophthalmology.*—Thursday, Nov. 13, 5 p.m. (Cases at 4.30 p.m.) Discussion: Policy in Dealing with Partially Sighted and Blind Persons. Openers: Mr. D. D. Stenhouse-Stewart and Dr. A. A. Newth.

*Clinical Section.*—Friday, Nov. 14, 5 p.m. (Cases at 4 p.m.)

LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.—Tuesday, Nov. 11, 5.15 p.m. Dr. Bernard Katz: Nature of the Propagation of Messages in Nerve. Wednesday, Nov. 12, 5.30 p.m. Dr. M. H. Pirenne: Physiological Mechanisms of Vision.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Monday, Nov. 10, 8.30 p.m. Discussion: Cardiac Pain. To be introduced by Dr. William Evans.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.—Wednesday, Nov. 12, 3.30 p.m. Prof. W. C. W. Nixon: Diet in Pregnancy (illustrated).

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Friday, Nov. 14, 8 p.m. Address by Mr. George Perkins: A Broken Ankle.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At West London Hospital, Hammersmith, W.—Friday, Nov. 14, 8.30 p.m. Clinicopathological meeting. Demonstration of Some Results of Medical and Surgical Treatment.

## POSTGRADUATE DIARY

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tuesday, Nov. 11, 5 p.m. Dr. I. Muende: Pathological Demonstrations. Thursday Nov. 13, 5 p.m. Dr. J. Franklin: Cutaneous Neoplasms.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, Nov. 11, 5 p.m. Prof. W. S. Tindal: The Modern Approach to Miracles.

EDINBURGH ROYAL INFIRMARY.—Thursday, Nov. 13, 4.30 p.m. Honyman Gillespie Lecture by Dr. E. A. Carmichael: Some Observations on the Dynamics of the Cerebrospinal Fluid.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Nov. 14, 5 p.m. Dr. J. R. B. Hern: Dyspnoea.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

SINCLAIR.—On Oct. 19, 1947, at East London, to Nancy, wife of Dr. S. A. Sinclair: Lovedale, a son.

IPTON.—On Oct. 31, 1947, to Leslie, wife of Ivor P. D. Skempton, M.B., B.S., second son—Howard White.

LIAMS.—On Sept. 21, 1947, in Nairobi, Kenya, to Philippa Gaffikin, M.B., Ch.B., wife of John G. Williams, twins—son and daughter.

## MARRIAGES

WILSON—GILLAN.—On Sept. 26, 1947, in London, William Proctor Wilson, C.B.E., B.Sc., M.J.E.E., to Agnes Christian Gillan, O.B.E., M.B., Ch.B.

## DEATHS

BEADLES.—On Nov. 1, 1947, John Nathaniel Beadles, M.B., B.S., of 85, Valleyfield Road, Streatham, S.W.

BRIDEN.—On Oct. 27, 1947, at 2, Adamton Terrace, Prestwich, William John Jardine Briden, M.B., Ch.B. (Edin.), aged 29 years. Late of District Asylum, Inverness, and dearly beloved husband of Anne Scott Morrison, S.R.N.

HINGTON.—On Oct. 14, 1947, at "Polentre," Falmouth, Colonel James Clarence Ledatt Hington, late R.A.M.C.

LYTLE.—On Oct. 26, 1947, Robert James Lytle, M.D.

PALETTE.—At Earls Colne, Essex, Thomas Edward Palette, M.D.

PIERCE.—On Oct. 26, 1947, at 14, Roland Gardens, London, S.W., Ward Irving Pierce, M.D.

RICHMOND.—On Oct. 23, 1947, at Dartford, Kent, Hugh Richmond, M.B., Ch.B. SCHWIZER.—On Oct. 22, 1947, as the result of a car accident, George Clemens Schwizer, M.D., Medical Officer, Shell Refinery, Ellesmere Port.

TRUMAN.—On Oct. 26, 1947, at Woodlands, Woodland Drive, Mapperley Park, Nottingham, Bernard Renshaw Beckitt Truman, M.B.

WEBER.—On Oct. 26, 1947, at West Cliff, Cliff Road, Sandown, Isle of Wight, Alexander Moxon Weber, M.S., F.R.C.S., formerly of 2, The Ropewalk, Nottingham.

WEEKS.—On Oct. 26, 1947, at Pershore Cottage Hospital, Courtenay Charles Weeks, M.R.C.S., L.R.C.P., Rector of The Combertons, Worcestershire.

WELCH.—On Oct. 26, 1947, at the Royal Naval Hospital, Haslar, Surgeon Rear-Admiral Sir George Welch, K.C.M.G., C.B.

## Any Questions?

*Correspondents should give their names and addresses (not publication) and include all relevant details in their queries which should be typed. We publish here a selection of the questions and answers which seem to be of general interest.*

## Quinine in Auricular Fibrillation

**Q.**—A middle-aged patient subject to frequent short attacks of auricular fibrillation finds that taking a 5-gr. (0.32-g.) tablet of ordinary quinine two or three times a day almost completely wards off the attacks. He has taken large quantities of quinine tablets over a long period; is there any danger in its continued use and is it a good treatment?

**A.**—Paroxysmal auricular fibrillation requires treatment only if the bouts are prolonged or frequent or if there is underlying heart disease. Sometimes they produce discomfort and anxiety quite out of proportion to their significance. The regularizing effect of quinine on the rhythm of the heart was recognized long before quinidine was introduced. Wenckebach recommended its use in a pill combined with nuxvomica: quinine sulphate gr. 3 (0.2 g.) with ext. nucis vomicae gr. 1/4 (16 mg.) twice or thrice daily. Probably this pill will suffice to control the attacks. Frequently the patient is able to anticipate the onset of attacks and can prevent them by taking the pills. If the measures are satisfactory they may obviate the need for larger doses which have been taken. Alternatively, quinidine gr. 3 (0.2 g.) twice or thrice daily may be taken with impunity.

## Allergy and the Endocrines

**Q.**—Is there any interrelationship between the production of histamine in the body and the endocrines? I have a puzzling case of vasomotor rhinitis associated with breathlessness, vertigo, and headache. This is thought to be allergic in origin but it is noted that the condition is aggravated during the premenstrual phase. Treatment on antihistamine lines, presuming an allergic factor is responsible, is contemplated; but would endocrine imbalance be remediable by oestrogen therapy (diethyl oestrol), either independently or in conjunction with the antihistamine treatment?

**A.**—The clinical influence of phases of the menstrual cycle and of pregnancy on some allergic conditions indicates relationship with the endocrines. It is also known that some patients react allergically to the injection of one of the hormones, even in pure crystalline state. Further, Zondek and his colleagues have demonstrated an apparent allergy in some cases to endogenous natural hormones. Intracutaneous injection may demonstrate allergic reactions to oestradiol, progesterone, testosterone, as well as to the pituitary trophic hormones. Such a reaction is obtained desensitization may be brought about by the daily injection of small and progressive doses of the appropriate hormone. Other aspects of allergy should not be neglected, of course, and may be more important in any particular case.

## Chilblains

**Q.**—A man aged 60 has had chilblains for several winters. He has fissures across his finger nails as a result of previous chilblains at the base of the nails, which keep reappearing. What is the probable cause and is there any helpful treatment?

**A.**—The cause of chilblains is unknown, but they are influenced by circulatory, nutritional, and endocrine disturbance and by environmental conditions of temperature and humidity. The combination of small doses of phenobarbitone, thyroxine and vitamin K may be helpful.

## "Dead-weight"

**Q.**—Why is a dead body much heavier than the same body alive—hence "dead-weight"?

**A.**—A dead body is not heavier than the same body alive. The complete inertness and lack of all co-operation, compensated frequently by the rigidity and consequent awkwardness of a dead body, give the impression of greater weight—this is the significance of the term "dead-weight."

### Loss of Hair during Lactation

**Q.**—During the successful breast-feeding of her first child a healthy woman of 28 noticed that her hair was becoming thin and was coming out in large quantities on combing. Hair growth became normal again after the baby was weaned. Now, four years later, she notices the same symptoms while nursing her second child. Is the causative factor for this known, and what treatment would be advised?

**A.**—Hair changes are not uncommon during both pregnancy and lactation. Many women notice alterations in the texture of their hair, which tends to lose its colour and glossiness. In others the hair becomes brittle or falls out, and the writer has noticed not only loss of scalp hair during lactation but also loss of hair from other areas, such as the pubes and eyebrows. Women with superfluous hair sometimes lose it during pregnancy and lactation. On the other hand, there are reports of the temporary development of hirsuties during pregnancy. The explanation of these changes is unknown—indeed, the whole subject of hair growth in different parts of the body and its sex differences is one full of intricacies which are not yet fully understood. Of the ductless glands, the pituitary, thyroid, adrenal, gonads, and placenta—one or all—may be involved. So far as loss of hair during lactation is concerned, it is tempting to postulate either an endocrine or a nutritional causal factor. Not everyone appreciates that the nutritional requirements during lactation are even greater than during pregnancy. Either endocrine or dietary therapy would be empirical but could be tried, bearing in mind that androgens and oestrogens might affect lactation adversely. Thyroid, however, should do no harm. If all else fails and the loss of hair is becoming so much as to cause alarm, lactation should be discontinued as soon as is reasonable from the standpoint of the baby.

### Aluminium and Gastritis

**Q.**—Is there any justification for the suggestion that gastritis can be caused by alum salts, which are normally insoluble in the soil but are rendered soluble by ammonium sulphate fertilizer? Up to 4 cwt. of ammonium sulphate is used per acre when the price of potatoes is high, and the point arises whether soluble aluminium salts find their way into the potatoes. Have any analyses been undertaken to settle this point?

**A.**—It is true that excessive quantities of ammonium sulphate added to a very acid soil will render some of the aluminium found in the form of complex silicates more soluble, but in agricultural practice this increased solubility is largely of theoretical interest. Assuming that small amounts of soluble aluminium compounds are liberated and are absorbed by root crops, the amount must be negligible. The consumption of minute amounts of aluminium compounds is not deleterious to health. This is borne out by the fact that aluminium cooking vessels have been in use for many years and large quantities of aluminium preparations are habitually consumed by some patients with peptic ulcer without producing gastritis.

### Localized Dental Erosion

**Q.**—A patient has some erosion of the buccal surface of both lower premolar and canine teeth; there is no erosion of the lingual surface of these teeth, nor are the upper teeth affected in any way. What is the cause of this condition and can you suggest any treatment?

**A.**—Erosion of the buccal surface of the teeth in the lower premolar and canine area is frequently in fact abrasion of these areas due to misuse or over-use of the toothbrush and paste. The premolar and canine areas, projecting slightly on the arch of the teeth, are more liable to receive abrasions from the toothbrush because of their position, particularly when the brushing is done in a horizontal plane rather than from the gums towards the biting surface. Cervical caries is also often seen in this area, the onset following this type of repeated abrasion, which in turn is followed by some recession of the gums allowing food particles to adhere to the enamel-cemental junction. If the eroded areas are clean and not carious, no treatment is required, but over-vigorous horizontal brushing of the teeth should be forbidden. If they are carious, the caries should be removed and fillings inserted in the ordinary way.

### Treatment of Dupuytren's Contracture

**Q.**—In a case of Dupuytren's contracture in the early stage, is any treatment available (excluding surgical operation) to prevent the fingers eventually folding into the palms?

**A.**—Until recently the only non-surgical form of treatment available for preventing progressive deformity in cases of Dupuytren's contracture was by means of daily stretching of the contracted tissues, usually carried out by the patient himself, and a continuous stretch at night by a splint keeping all the digital joints in maximum extension. This treatment might delay but frequently failed to prevent the development of the deformity. Recently it has been claimed that vitamin E has an effect in preventing progression of the disease. The method is still on trial, but some encouraging results have been obtained. The dosage recommended is 100 mg. three times daily for a few weeks until satisfactory improvement is secured, followed by a maintenance dose of 1 mg. per kilo of body weight. The drug is administered orally in tablet form.

### Weekly Ultra-violet Therapy

**Q.**—Are there any dangers in exposing one's skin to ultra-violet light once weekly for an indefinite period to control a most intractable acne vulgaris? The time and distance are regulated to secure a first-degree erythema with subsequent desquamation. I notice a very small discrete red spot developing, resembling a purpuric lesion. Is it safe to proceed with treatment?

**A.**—No known risk attaches to weekly exposure to ultra-violet irradiation calculated to produce a first-degree reaction. It may be expedient, however, to interrupt such treatment for a matter of two months in order that the skin may lose its tolerance to these rays; on resuming the treatment the desired reactions should be obtained with a smaller dosage. It is doubtful if a single discrete red spot could be attributed to the exposures, but should this persist or increase in size, it would be advisable to seek the opinion of a dermatologist.

### Acne Rosacea

**Q.**—A healthy woman of 55 has suffered for nine months from a periodic reddened papular eruption which usually appears symmetrically on the face, but occasionally on one side and the next day the other. It is now spreading to the forehead. Tortoiseshell spectacles are worn for reading, and the condition is more pronounced where the frames touch the skin, causing irritation and being aggravated by heat and radiation from a fire. It dies down overnight, but not completely. No medicines are being taken, and no particular food seems to be associated with the rash. What are the cause and the treatment?

**A.**—The condition described is probably rosacea and of menopausal origin. There may also be a contact dermatitis present from the spectacle frames, though this has not been described in relation to pure tortoiseshell. Soap and water should be avoided on the face; ordinary cosmetics should be used by day and a 2% sulphur and salicylic-acid ointment applied lightly at night. A very small dose of unfiltered x rays (70–100 r at 60 kV.) is helpful. Phenobarbitone gr. 1/2 (32 mg.) at night and stilboestrol 0.5 mg. daily, rest, restricted carbohydrates, and the avoidance of hot and irritating foods and of strong tea should be advised.

### Legal Definition of Consummation

**Q.**—A woman aged 38 married her second husband seven years ago. He has no interest in sex, but is an otherwise excellent husband. They had intercourse on a few occasions when first married, and then more rarely, the last time being over a year ago. He always used a condom. They do not sleep together. I suggested that I should see her husband, but she said he would probably order me out of the house. Would a psychiatrist help? Has the marriage been consummated from the medico-legal point of view?

**A.**—It is possible, although not very likely, that the man has some organic defect, such as testicular atrophy. Many men have little interest in sex: it is part of their individual make-up, or perhaps more especially of their upbringing and mode of

life. Marriage at a comparatively late age might also be a factor. The management of the case will depend on aspects such as these. A psychiatrist might help, but only if the man is willing and anxious to co-operate.

The question whether the marriage has been "consummated" is hardly a medico-legal one; it is rather a question of the legal definition of the term "consummation." This was discussed at length and very helpfully by one of the leading authorities on divorce law, Mr. William Latey, in a paper read before the Medico-Legal Society, and reported in the *Medico-Legal and Criminological Review*, 1946, 14, 51.

In the case quoted there was undoubtedly "consummation," since the parties are said to have "had intercourse on a few occasions when first married." This case must therefore be distinguished from that of *Cowen v. Cowen* (1946) in which a marriage was declared on appeal to be a nullity, on the ground that the husband had persisted in using a condom, against the wishes of his wife. This was held to be a failure to consummate, so giving the petitioner a right to a declaration of nullity under section 7, subsection i (a), of the Matrimonial Causes Act, 1937 (the "Herbert" Act). A petition on this ground would fail if the wife did not satisfy the Court that she had always objected to the use of this contraceptive device. The wife may have another remedy; if she can prove to the satisfaction of the Court that the husband's conduct has had, or is likely to have, a serious effect on her health, this may constitute grounds for divorce by reason of "cruelty" on his part.

#### Lead Contamination of Water

**Q.**—Would you consider the presence of lead in a public water supply (pipe service) to the extent of 1/350 gr. of lead per gallon (0.04 mg. per litre) injurious to health when consumed, over a period of many years? If so, what symptoms might be expected?

**A.**—One authority states that 2 mg. (1/32 gr.) absorbed daily will in time undermine the constitution and set up chronic lead poisoning with changes in the kidneys and arteries which will shorten life (*Industrial Maladies*, by Sir Thomas Legge, p. 47).

#### NOTES AND COMMENTS

**Ejaculatio Praecox.**—Dr. K. F. D. SWEETMAN (Kuala Belait, Brunei) writes: This evening while relaxing at the end of a day's work I opened my latest copies of the *B.M.J.*, which arrived only an hour or two before, and tucked away in odd corners I found in two copies (June 28, p. 958, and July 12, p. 82) references to the treatment of the condition known as ejaculatio praecox. It seemed to me that both articles dismissed the subject rather summarily without touching upon several important points. Ejaculatio praecox is not by any means of no consequence; it can be the cause of serious marital maladjustment, causing frigidity on the part of the wife and, from this, antagonism and even open anger in the first or ending male. Several factors should be considered before attempting to treat this condition, some of them being:

The build of the male sexual organs. Often one finds the penis a little shorter than normal, a circumcision which has cut the prepuce too short, or some mild condition of chronic inflammation. Local causes are by no means the only or main factor concerned, because one may find that the patient sometimes has an ejaculation before he can commence the act of intercourse. (2) The mental make-up of the man concerned. Almost invariably they are what is called "a little highly strung," without there being any suggestion of mental pathology, though a state of anxiety may be caused secondarily from marital maladjustment arising from premature ejaculation. No amount of local anaesthetic applied to the genitals can overcome this factor. (3) The woman. Frigidity, opposition, inexperience, or lack of co-operation occurring in the female partner may decide the occurrence of ejaculatio praecox in a borderline case and most certainly aggravates it enormously. Also frigidity, opposition, and passivity can follow continual ejaculatio praecox. Fear of pregnancy can make a normal warmly reacting woman passive, frigid, or frankly in opposition.

In treating a case of this condition all these and other factors as well must be taken into consideration. My experience has been that it is impossible to eradicate the condition; whatever is done only lessens the degree of disability, but this is no bar to a successful marital adjustment for both partners, the real aim of treatment. At the commencement any general or local pathology should be eliminated and treated, at the same time making sure that the

symptoms complained of are not temporary, due to mental stress, business worries, etc., and other factors of a non-sexual nature, or over-indulgence. This leaves to be treated what one might be excused in calling true ejaculatio praecox. From the outset both partners must be considered, their confidence obtained, and separate advice given. Where the woman is concerned plain speaking is necessary and she must be convinced that she can do a lot to help her husband. More active movement on her part and love play extragenitally will take her husband's mind away a little and lessen his mental tension, and a dorsal position with the legs raised and flexed more than usual will facilitate full entry, all these manœuvres tending to hasten her own orgasm, thus lessening greatly the difference in time between hers and that of her husband. Secondly will follow also an increased flow of natural secretions and lessened friction.

The man should not indulge in intercourse if overtired, sick, emotionally upset, or if his wife is obviously in a non-responsive mood. It is also a help to avoid intercourse when the bladder is full. Though I have found local anaesthetics alone to be of little use, a lubricant used on the penis to decrease local friction is a definite help to both parties. Oleum arachidis I have found to be as good as any and practically odourless as well as non-irritating. He should be advised to indulge in extragenital love play to distract his attention a little and thus decrease his mental tension. Alcohol in small quantities is an asset to treatment; it helps to prolong the erection and abolishes some of the mental tension at the same time as the higher cerebral controls. All of these points are only contributory and cannot cure the condition, though they are essential to what treatment should aim at—satisfactory orgasm and sexual satisfaction for both man and wife. These points all tend to one result—earlier orgasm for the woman and a later one for the man. In some cases they will be enough, but not continually.

I consider the next step the most important—that is, to train the man to maintain his erection after the premature ejaculation. The longer the duration of the erection before ejaculation the easier it is, and for it to occur there must be the minimum of local friction. With training this can be regularly accomplished, if intercourse is limited to say once or twice a week. Once accomplished the woman can be carried on to her own orgasm, which is often accompanied by a second orgasm on the man's part, or he can relax with no ill effects, as one climax has been accomplished. This procedure can be readily accomplished by practice and involves no unpleasant or awkward and prolonged measures. If some frigidity of the woman is present make sure this is not due to fear of pregnancy; and, if so, abolish this by prescribing a suitable and safe method of contraception—preferably not elaborate, and using, if possible, a substance which acts as a lubricant as well. Condoms are definitely contraindicated. This rather lengthy discourse is not meant to be an authoritative treatise; it is merely an account of the condition drawn from my own observations and experiences in patients treated.

#### Corrections

Dr. LESLIE HARRIS writes: In my passing allusion ("All the Vitamins," Nov. 1, p. 683) to recent observations on the treatment of lupus vulgaris by massive doses of vitamin D, I should have written "by massive doses, orally or by injection" rather than "by massive local injection." Administration by mouth has of course been the procedure described in most accounts, although, for example, Dr. D. E. Macrae (*Lancet*, Jan. 25, p. 135) treated some cases by intramuscular injection and some by mouth (either oily solution or emulsion) and concluded that there was no difference in the results obtained by the different methods of administration. Incidentally, the international unit is 0.025 µg. of calciferol, not 0.02 µg. as printed.

The price of *Human Genetics*, by Prof. R. R. Gates, which was reviewed on July 12 (p. 57), has been reduced to £3 15s.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 8 1947

## British Medical Association

### PROCEEDINGS OF COUNCIL

Wednesday, Oct. 29, 1947

A meeting of the Council was held at the House of the Association, Tavistock Square, on Oct. 29, with Dr. H. Guy Dain in the chair.

The death was reported with regret of a former member, Dr. John Goff.

The Chairman stated that on behalf of the Council he had authorized the presentation of a Humble Address to Their Majesties on the marriage of the Princess Elizabeth. The Council endorsed his action by applause.

#### National Health Service Act: The Next Step

The Council considered the various resolutions of the recent Annual Representative Meeting which bore on the National Health Service Act, and the Secretary repeated the expected order of events, as set out in the *Journal* of Oct. 25 (p. 661), following the receipt of the Minister's reply to the representations of the Negotiating Committee. If the Minister's reply was available in documentary form a fortnight after the meeting with him fixed for Nov. 11 and 12, it would be possible to issue at the end of November in a combined document the considered case as represented to the Minister by the committee and the Minister's reply. This would be sent to all members of the profession, and a special meeting of the Council would be summoned to consider the form of a plebiscite and the calling of a Special Representative Meeting in the light of what the Minister had said.

The Chairman expressed the view that the Council would be wise to determine, in advance of the plebiscite returns, the character of the support it would need, as expressed in minimum percentages, to justify it in advising the profession to accept or not to accept the Service, and, after discussion, this view was generally accepted by the Council, though the decision as to the minimum percentage to be taken was deferred.

The resolution on midwifery services in which the Representative Body declared that all registered practitioners should be entitled to undertake domiciliary obstetrics under the Act and that ten years' experience in domiciliary obstetrics was an adequate preliminary condition of entry to an examination for a postgraduate diploma was considered. The Council endorsed the view expressed by the Chairman that the proper course was to confine themselves to a condemnation of Section 23 (3) of the Act, which added the words "including conditions as to the qualifications of such medical practitioners" to the section of the Midwives Act, 1936, which enables the Minister to prescribe conditions subject to which fees are to be payable by the local health authority to practitioners called in by midwives.

#### Shortage of Nurses: Committee Appointed

The Annual Representative Meeting called upon the Council to request the Minister of Health and the Secretary of State for Scotland to give urgent attention to the problem of the shortage of nurses and to set up a special committee for the purpose. The Council agreed, and the following were appointed to the new committee: the four principal officers of the Association, the chairmen of the Hospitals, Consultants and Specialists,

General Practice, Scottish, and Public Health Committees, Drs. Janet Aitken, E. B. Brooke; O. C. Carter, Mary Esslemont, A. C. Foster-Carter, A. Staveley Gough, C. G. Martin, W. G. Masefield, J. B. W. Rowe, Alex Smith, and C. O. Stallybrass, with two members nominated by the British Hospitals Association, two by the Royal College of Nursing, and one by King Edward's Fund, and with power to co-opt.

On the report of the Scottish Committee it was stated that, in common with a number of other medical bodies in Scotland, it had been invited by the Secretary of State to submit views on the recommendations of the Working Party on the Recruitment and Training of Nurses, and it was inviting the other bodies to co-operate in a joint committee with a view to preparing an agreed statement for submission to the Secretary of State. The other bodies, numbering about nineteen, had agreed to this proposal.

It was agreed, on the recommendation of the Science Committee, to award three Association prizes annually, each of the value of 20 guineas, and three further prizes, each of the value of 10 guineas, for essays by nurses on selected subjects. The subjects for the first award were "Suggested Improvements in the Methods of Training Nurses," "The Nurse-Patient Relationship," and "Difficulties of Domiciliary Nursing."

#### World Medical Association

A long report by the Hon. Secretary of the World Medical Association (Dr. Charles Hill) was laid before the Council. It recounted the decisions of the first annual meeting of the Association in Paris in September last, which was the subject of a leading article in the *Journal*. The report set out the constitution which was adopted, the details of subscription, membership roll, secretariat, and election of officers, and the report of a committee which was set up to formulate a recommendation on the attitude of the profession to war crimes.

Dr. J. A. Pridham, one of the B.M.A. representatives at the conference, who was elected a member of the first council, gave an interesting account of the proceedings in Paris. He said that the delegates worked very hard in extremely hot weather, and many of them gave up social occasions in order to leave more time for discussions. There was controversy, severe at times. Underneath some of the controversies was a fundamental difference between the French and the English-speaking countries in their conception of the new Association, differences too great to be bridged by compromise. But contention was better than apathy and showed that something big was being built. There were errors of tact on all sides, and all learned useful lessons, but the great fact emerged that nobody was prepared to leave the W.M.A. or to wreck it. He reminded the Council of the precursor of the W.M.A., the A.P.I.M., a body limited to Europe. The idea of the W.M.A. began with a tea-party in B.M.A. House in 1945, was followed by an impressive gathering of the representatives of 30 nations, again in London, in 1946, and finally took shape at this Paris meeting, when 47 nations were represented and all five continents. It was unfortunate that the debate on the relations of medicine

and the State, which was to have been opened by Dr. Dain, and for which the French secretary, Dr. Cibric, had prepared an impressive document, was crowded out, but even with very limited opportunity the Chairman of Council made the kind of impression to which they were all accustomed.

Dr. Pridham concluded by saying that, if United Nations and its subsidiary bodies such as the World Health Organization were to succeed, it was absolutely necessary that there should be a world body to represent the opinion of the medical profession. The doctors of the world possessed tradition, knowledge, and ethics which were of vital importance to humanity, and they must have a powerful organization which could speak in their name with authority. It was evident from the meeting in Paris that Britain and the B.M.A. were respected, and he believed the B.M.A. could and must give valuable guidance to the World Association which it had done so much to bring to birth.

#### The "Doctor" Sign on Cars

Dr. S. Wand, chairman of the General Practice Committee, brought forward a recommendation that, notwithstanding an earlier decision, no objection be raised during the period of petrol restrictions to the use by members of the profession of "Doctor" signs on their cars. Mr. R. L. Newell spoke against this recommendation. During the war the sign must have helped doctors to get through a blitzed area, but those conditions no longer existed. Dr. N. E. Waterfield also opposed. Dr. F. Gray spoke in favour. As doctors had the right to use their cars during a period of petrol restriction it was only reasonable that they should be able to avoid being stopped and questioned by the police. Dr. J. B. Miller suggested that when the car was parked the sign might attract the attention of thieves. Dr. R. W. Cockshut suggested some less prominent sign which would be known to the police but would not seem like advertisement. The recommendation was carried and it was agreed that, failing issue by a Government department of an official distinguishing sign, labels of a smaller design than those used during the war might be reissued through local Divisions.

The General Practice Committee report included a statement on action taken on over 30 separate matters.

#### Industrial Medicine

Dr. Vaughan Jones introduced a report of the Industrial Medicine Committee, the principal matter in which concerned the salaries of industrial medical officers, and eventually a recommendation on this question was carried, but was subject to an undertaking by the chairman of the committee to study again the question of increments within the range of salaries suggested, on which it had not so far been thought advisable to lay down specific figures and to define the term "assistant industrial medical officer." It was considered that the minimum commencing salary of a whole-time industrial medical officer in charge, single-handed or with assistants, should range from £1,000 to £1,750 according to the degree of responsibility, qualifications, experience, and age, and that of an assistant industrial medical officer should be £850.

The committee also submitted its replies to a questionnaire issued on behalf of the Industrial Health Advisory Committee of the Ministry of Labour and National Service on the development of industrial medical services. The replies were criticized in respect of certain details, and eventually Dr. Vaughan Jones agreed that the committee should look at the report again in the light of the suggestions made.

Dr. I. D. Grant presented a report of the Joint Evidence Committee concerning the scheduling of diseases as industrial diseases under the Workmen's Compensation Acts. The committee had included representatives of the B.M.A., the Association of Industrial Medical Officers, and the Association of Certifying Factory Surgeons. The committee was unanimous in arriving at its report.

Dr. Wand said that this was an excellent report, one of the best pieces of committee work that had come to the Council for a long time. Dr. Cockshut referred to the absence of any recommendation for the education of medical referees. Most of these people were out of touch with factory life, and never saw a factory from one year's end to another.

The Chairman said that this and other points could be brought out in oral evidence which the committee would give to the Departmental Committee on Industrial Diseases.

Dr. Grant said that the committee was indebted to Dr. Agnes Kelynack, Assistant Secretary of the Association, who was responsible for the memorandum.

#### Consultants and Specialists

On the recommendations of the Consultants and Specialists Committee, whose report was introduced by Mr. A. M. A. Moore, it was agreed that no action be taken at the present time to review the salaries of E.M.S. specialists; that in view of the appointment of the specialist Spens Committee no further action be taken at present to reconsider the minimum salaries for whole-time consultants and other appointments in the public health service; and that representations should be made to the Minister of Pensions that specialist members of his Ministry's medical boards should be remunerated at the rate of 4 guineas a session, and to the Ministry of Health urging the continued payment of part-time consultant members of the staffs of voluntary hospitals. Attention had been drawn to the action of the Minister in refusing to pay part-time consultant members of the staff of a provincial voluntary hospital and proposing to appoint a smaller staff of full-time consultants.

#### The Marriage Bar

Dr. J. Fenton, chairman of the Public Health Committee, brought forward a recommendation reaffirming the policy of the Association enunciated some 20 years ago that, in considering grounds for the appointment or dismissal of a woman medical officer, marriage should not be made a reason for withholding or terminating an appointment. This was agreed to, and it was further agreed that a copy of the resolution should be sent to the Negotiating Committee and to the Glasgow Corporation and Northern Ireland Government, two authorities which impose the marriage ban so far as women medical officers are concerned.

The report of the Public Health Committee contained an account of the negotiations which have led up to the second interim revision of the Askwith memorandum. Dr. Fenton mentioned that the Society of Medical Officers of Health had conveyed an expression of appreciation to the Chairman of Council for the part which the Association had taken in arriving at the new percentage increases of the Askwith scales.

Some twenty other matters on which action had been taken were contained in the Public Health Committee's report.

#### Co-ordination of Policy on Remuneration

Dr. E. A. Gregg presented the first report on the committee concerned with co-ordination of policy on remuneration. It contained one recommendation—which was agreed to—that the question of the sessional fee for refraction work be discussed again with the local-authority associations when other questions relating to the payment of medical practitioners employed on a part-time basis by local authorities were under consideration. The bulk of the work of the committee, however, concerned the comparison and co-ordination of the proposals of the various committees with regard to fees, and rates of remuneration generally, and in one case it was able to point to, and secure the rectification of, a disparity between the proposals of two committees in respect of salary scales for similar employment.

The Chairman of Council said that this obviously was a very useful committee, and it had been instructive to review the scales of salaries and fees in so many and various fields of activity.

#### Organization and Public Relations

Dr. Pridham, for the Organization Committee, proposed the establishment of a standing committee on medical films to manage the Medical Film Bureau and the Film Library and to deal generally with matters concerning medical films. This was agreed to.

It was agreed also that a special committee be set up to examine and report on the relationship of the Association to the profession in the Dominions of India and Pakistan. The

position of B.M.A. members in Burma and in Ceylon was added to the committee's reference.

The report of the Public Relations Committee was presented by Dr. Guy Dain. Mr. Newell congratulated the committee on the popular illustrated edition of the report on the care and treatment of the elderly and infirm, entitled *When You are Old*.

#### A Nutrition Committee Appointed

The Council agreed to appoint a special committee to consider problems of nutrition, including present nutritional standards. This is to be a scientific committee, making a factual report to the Council. The Chairman of Council and the Chairman of the Science Committee (Dr. R. G. Gordon) were authorized to decide its composition. The Chairman said that it had been stated in the report of the Committee on Nutrition appointed before the war that a certain number of calories was essential. The number provided by the present ration was much smaller, and therefore it seemed to be imperative to set up a committee to consider how the present food standards reflected on the national health.

#### Empire Medical Advisory Committee

In June last the Council resolved to establish an Empire Medical Advisory Bureau, and the Finance Committee now brought forward a scheme of organization for approval. The object of the Bureau was generally to provide a personal advisory service to practitioners visiting the United Kingdom, particularly those from the Dominions and Colonies. The service would include the making available of information concerning facilities for postgraduate study, as well as a wide range of other information, the maintenance of a register of suitable lodgings and hotels and the arrangement of private hospitality, and the organization of social functions and other means to enable practitioners from different parts of the Empire to meet each other and prominent members of the profession in this country. Proposals were made for staffing and finance. The scheme was expected to cost between £4,000 and £5,000 in the first year and more in subsequent years.

The present idea was that practitioners from the Dominions and Colonies should be encouraged to come to this country, and when they came should be encouraged also to make their first call at B.M.A. Headquarters and that the organization there should be available to give them what help they needed.

Dr. J. H. Anderson said that this proposed organization offered a good opportunity for liaison with Branches overseas. Dr. J. G. M. Hamilton reminded the Council that London was not contemporaneous with Great Britain and that there should be co-operation with Branches at home as well as overseas. The Chairman said that it would, of course, be assumed that some of the visiting practitioners would want to go to provincial centres and to Scotland.

A discussion took place on possible alternative titles, but "Empire Medical Advisory Bureau" was most favoured.

The recommendation was agreed to and a committee of management appointed.

#### Churches' Council on Healing

Dr. Waterfield, for the Central Ethical Committee, said that his committee had discussed the relationship of the Association with the Churches' Council on Healing. It had been feared that members of that body had been adopting unscientific and psychologically unsound methods. A deputation headed by the then Bishop of Croydon (now Bishop of Lincoln) had been received and a lucid description given of the Council's work. The deputation completely allayed the fears of the committee, and a statement had been prepared for submission to the B.M.A. Council and to the Churches' Council on Healing setting out the result of the discussions, which had made it clear that the Churches' Council was doing valuable work and that there existed a field for legitimate co-operation between the two bodies. The statement is published in the *Supplement* at p. 112.

A question was asked by one member whether the list of churches adhering to the Central Council included the Church of Christ Scientist, and the reply was that it did not. The Council was set up by the late Archbishop Temple to co-ordinate the activities of some 13 denominations or groups of churches.

The Chairman said that there was no desire on the part of the Churches' Council to overlap the realm of physical or psychiatric medicine. These churches claimed, quite properly, their place in the work of healing, but they made no claim to heal by laying on of hands or pouring of oil. They wished to provide healing for the spirit.

Dr. Cockshut said that he regarded this statement as a most thrilling document. Very often doctors did not have any contact with the clergy, and very often they did not seem themselves to get to the root of what was wrong with the individual. He envied the members of the Ethical Committee their privilege in starting something which might prove to be of very great importance.

The statement was unanimously approved, and it was agreed that representatives of the Association be appointed to the Churches' Council on Healing.

In June, 1946, the Council approved a statement which had been prepared for the assistance of practitioners who were asked to co-operate in the work of the National Marriage Guidance Council. The statement was now again submitted after revision and agreement between the Central Ethical Committee and the Marriage Guidance Council. The alterations, of a very minor character, were approved. Dr. Dornan objected to the setting up of a list of medical practitioners deemed suitable to provide the advice required. He thought that inclusion in the *Medical Register* should be sufficient. Dr. Sutherland said that the list was open to all practitioners who expressed themselves as competent and willing to render the service required.

The objections were not pressed and the statement was approved.

#### Scottish Committee

Dr. G. MacFeat presented the report of the Scottish Committee, some of the matters in which have been referred to under earlier headings. He said that a liaison committee had been set up with the Scottish Division of the British Dental Association. The list of members of the Regional Hospital Boards will be found on p. 111. The Scottish Committee had been asked to provide reading-room facilities for postgraduate students in Edinburgh, and it was happy to furnish such accommodation at Headquarters.

Dr. Forbes referred to one matter touched upon in the Scottish report—the fees for reports required by procurators fiscal. The fees in certain cases appeared to be below the fees in England, and it would be desirable to have some co-ordination. Dr. MacFeat agreed that the suggested scale of fees should be reconsidered by the Scottish Committee. The Chairman pointed out the desirability of submitting such questions to the new Committee on Co-ordination of Remuneration. It was agreed that the membership of the Co-ordinating Committee should include the chairman of the Scottish Committee. Dr. MacFeat.

#### Colonial Medical Service

Dr. J. B. W. Rowe presented a report from the Dominions Committee, the chief matter in which concerned the terms of service in the Colonial Medical Service. It was agreed to draw the attention of the Colonial Office to the inadequacy of the present salary scales, and to inform the department that the Association proposed at a later date to raise the whole question of these salary scales in the light of the findings of the Spens Committee. In the meantime it was felt that negotiations with the department should be opened with a view to securing the adoption retrospectively of percentage increases in the pre-war salary scales on the basis of the second interim revision of the Askwith memorandum. The Colonial Office would be asked to reach a decision on this latter question by Dec. 31 next.

#### Other Business

Sir Victor Richardson presented the report of the Armed Forces Committee. He said that there had been a deputation from the committee to the Ministry of Commonwealth Relations with regard to the compensation, etc., of officers compulsorily retired from the Indian Medical Service. The committee had prepared a draft of what took place at that meeting, but the draft was still under consideration.

A report was produced from the Arrangements Committee for the Annual Meeting at Cambridge in June next. It contained the nominations for the officers of the sections. Dr. C. M. Stevenson said that the Cambridge people were satisfied with the nominations offered to them and thought they had been treated generously.

A report of the Aliens Committee of the Central Medical War Committee was placed before the Council. This drew the attention of the Council to certain points in connexion with the recently introduced Medical Practitioners and Pharmacists Bill, which provides for permanent registration of certain temporarily registered practitioners and provisional registration of certain others. The Minister, said the Chairman of Council, had now agreed to fix a date after which an alien coming into this country—say, as a farm worker—would not be able at the end of twelve months to go on to the *Medical Register*, a thing which had been happening.

On the motion of the Science Committee it was agreed to suggest to the secretaries of Regional Hospital Boards and university postgraduate committees that postgraduate committees should be modified to ensure the inclusion of representatives from the staffs of local hospitals, local medical societies, and Branches or Divisions of the B.M.A.

Reports were presented from the Insurance Acts and the Hospitals Committees. The business contained therein has already been published in the *Supplement* in the reports of the meetings of those committees. Routine reports were made by the Journal, Staffing, and Building Committees, and a progress report by the Joint Committee on Psychiatry and the Law.

The Council, which had assembled at 10 a.m., rose at 5.30 p.m.

## ANNUAL PANEL CONFERENCE

### THE MINISTRY OF HEALTH DISCUSSIONS

The Annual Panel Conference of representatives of Local Medical and Panel Committees was held in the Great Hall of B.M.A. House, London, on Thursday, Oct. 30. Dr. J. A. Brown (Birmingham) was in the chair, supported by Dr. E. A. Gregg (chairman of the Insurance Acts Committee) and Dr. Charles Hill (Secretary).

At an early stage in the conference, in view of a number of motions on the agenda calling for a statement of the position with regard to the National Health Service, Dr. H. Guy Dain, Chairman of Council, spoke on the discussions which have been taking place.

#### Dr. Dain's Statement

Dr. Dain: In February last, after the plebiscite had shown a majority against any negotiation with the Government, the Minister finally accepted the terms upon which he had agreed to enter into discussion—namely, that the possibility of an Amending Act should not be ruled out. The Minister himself on the first occasion met the Negotiating Committee and said that the amendment of the Act was a possibility. Later subcommittees dealing with various parts of the Act were set up, and from February to July a complete examination of the whole structure of the Act was made. These talks were not with the Minister himself but with his officers, and the arrangement was that when they were completed the case which had been put forward on behalf of the profession should be reported to the Minister by his officers. The committee, in order to ensure the proper emphasis on the points for which it was contending, also prepared a document for presentation to the Minister, restating the arguments used for the principles they desired to see established in the Service. The subject at the final meeting with the officers of the Ministry was partnership agreements, and it has been possible to show that sect. 35 of the Act is entirely unworkable.

On a number of grounds a case has been established for the amendment of the Act. The more the case has

been argued the more satisfied are those who speak for the profession of the soundness of their principles. I may say that on matters relating to partnerships, agreements, and purchase and sale of practices we have had the best legal advice we could get and have tendered that advice to the officers of the Ministry.

The Minister has undertaken to see us on the afternoons of Nov. 11 and 12, and it is expected that he will then, or soon after, give his answer and say whether and to what extent he is prepared to amend the Act. Our own document and the Minister's reply will afterwards be circulated to every member of the profession. The Council of the Association will meet and decide on the subsequent procedure. It will seek to obtain from the Representative Body an expression of opinion, which will be conveyed to all members of the profession at the time when they will be asked, in a second plebiscite, whether or not they are prepared to accept service. The committee's document is in complete pursuance of what has been laid down at Representative Meetings. There is no secrecy at all about it, but there would have been no point in reporting the discussions week by week, for the arguments used were familiar ones, and the officers of the Ministry of course had no authority to make an official reply. I am very sensible of the patience and forbearance which the members of the profession have exercised over a period of months during which they have received very little information—a period prolonged by the holiday season—but they can be assured that, whatever misgivings have been felt in some quarters, there has been no departure whatever from the principles by which we stand. (Applause.)

#### Questions by Representatives

Dr. J. A. Ireland (I.A.C.) said that the basis of compensation was causing some perturbation. On what basis was it to be assessed—1939 or present-day figures?

Dr. W. D. Steel (Worcester) asked whether it was contemplated that there would be a Representative Meeting before the plebiscite.

Dr. A. C. E. Breach (Kent) said that even to representatives in that hall, who were mostly in close touch with events, the period had been one of disquiet and uncertainty, and in the rank and file the long delay had meant a decline in enthusiasm and a risk of apathy.

Dr. A. V. Russell (Wolverhampton) said that the Minister on one occasion had told an enthusiastic audience that the doctors were at last beginning to see reason and willing to dance to his tune. They were not willing to dance to any such fiddle or to give up their freedom. Could Dr. Dain say whether the Minister was likely to launch a "blitzkrieg" after this "phony peace"?

Dr. F. E. Gould (Wolverhampton) asked whether any idea could be given as to how long it would be after the "appointed day" before compensation would be paid to those who were in a position to receive it.

Dr. R. W. Cockshut (I.A.C.), speaking as a "die-hard" opponent of the Act, told the conference with confidence that nothing whatever had been given away during these discussions. Except for Dr. Dain and the Secretary, the members of the Negotiating (or better called, the Discussions) Committee had had only a small part to play. The prolongation of the discussions had been an advantage because the further they had gone along the road the better they had been able to point out how this or that would not work. Before they entered upon these discussions many of them were opposed to the Act on principle, but after listening to the discussions he at any rate, if he had been favourable to the Act on principle, would now as a reasonable man have been opposed to it from the point of view of practicability. The procedure Dr. Dain had outlined could not be bettered as a means of ensuring that the voice of the profession would be heard.

Dr. W. Fraser (Cumberland) asked whether the committee still adhered to the principles regarding sale of practices, direction, and capitation fee.

Dr. J. A. Pridham (I.A.C.) endorsed all that Dr. Cockshut had said. He hoped they would not consent to receive a penny of compensation, but would zealously preserve the right to buy and sell goodwill.

Dr. Dain, in reply, said that compensation had not been discussed with the Ministry because they had had no instructions from the Representative Body that it would be willing to accept the loss of goodwill which compensation would involve. The problem of what it would cost the Government to make compensation was entirely outside the discussion. A formula was prepared for their own purposes when the matter was first broached, but the Negotiating Committee had never said a word to the officers of the Ministry on that question. He asked the Secretary to explain the formula.

Dr. Hill said that in the computation of the £66 millions in the Act there was taken by the Government the aggregate pre-war general-practice gross income on the basis of the figures collected by Prof. Bradford Hill in the statistical evidence prepared for the first Spens Committee. If that aggregate was multiplied by 2 and an amount equal to 16% added to the product, the result was rather less than £66 millions. If, again, the aggregate was multiplied by 1.9 and 22% was added, a similar figure was obtained. It was provided in the Act that there should be available for compensation a global sum of £66 millions or an appropriate proportion thereof. If there were fewer than 17,700 practitioners entering the Service there would be a deduction from the £66 millions of an amount equal to one-17,900th part on account of each practitioner to the number falling below the figure stated, but for every practitioner in excess of 17,900 there would be no proportionate increase in the £66 millions.

Dr. Dain, continuing, said that it was impossible to determine what would be the share of any particular practitioner for a long time after the "appointed day," so that any practitioner who was waiting until July 5 in order that he might then retire and claim his compensation was living in a fool's paradise. There would be a Representative Meeting before the plebiscite. A lead would be given by the Representative Body before the plebiscite vote was taken. Some reference had been made to statements by the Minister which suggested that he had the profession eating out of his hand. It was his policy, of course, to tell that to his public.

He agreed that there might have been a damping down of enthusiasm in view of the long interval, but that was not altogether a bad thing. It was out of the question to suppose that enthusiasm could be kept at a high pitch over very many months, and it would rise again and be effective at the proper moment. The committee had put in the forefront its opposition to the abolition of sale of practices and to direction of doctors, and its insistence on the method of remuneration by capitation fee; it had not receded in any way. Were they likely to get what they wanted? They had no idea. The officers of the Ministry, quite rightly, had not given away what the Minister might do. It was for the profession to see to it that he did what they wanted.

Dr. Gregg, in the name of the conference, expressed warm thanks to Dr. Dain. The fact that they had had a discussion of this kind was an indication of the importance attached to the present conference. Every representative was a key man; he was a man who was looked up to and whose opinion was sought in his own area. Someone had talked about enthusiasm. This matter was not going to be brought to a successful conclusion on a wave of enthusiasm but only by dogged determination. He was sure that the profession was satisfied in its leaders. There was no one who was not sure of Dr. Dain. They had had opportunities of trying him out over many years. He had been with them in many a fight and they had full confidence in him and in those associated with him. He begged each of them in his local sphere of influence to act with determination never to surrender until this matter was brought to a successful conclusion. This would be something to wipe out the criticism brought against the profession in 1911. Then they were not united together—they had had no opportunity of uniting. To-day the doctors were a firmly united body, and working together under such leaders he had not the slightest doubt about the result.

The vote of thanks to Dr. Dain was accorded with acclamation.

On a motion by Glasgow it was agreed that, if and when terms came to be discussed, the Insurance Acts Committee, as experts, should be consulted on the capitation fee before negotiations began.

## ANNUAL REPORT OF INSURANCE ACTS COMMITTEE

The Conference then turned to the discussion of the report of the I.A.C., published in the *Supplement* of Oct. 4 (p. 77).

### N.H.I. Certificates

Dr. J. F. Clarke (Montgomeryshire) moved that the Minister be informed that practitioners would issue N.H.I. certificates for N.H.I. purposes only, and that where an employer asked for evidence of incapacity the approved official forms as issued by the Ministry of Labour and National Service should be used. He had statements by three firms in his own town to the effect that it was their custom to ask for any type of certificate as to incapacity. Workmen objected to paying a shilling for a certificate when the N.H.I. certificate could be used for nothing. While practitioners did not want to multiply certificates, he did not see why the very concise form issued by the Ministry of Labour, for which a fee of 1s. was payable, should not be used.

Dr. J. O. McDonagh (Perthshire) thought the motion inexpedient at a time when they were fighting for less certification. Personally he was always thankful not to have to sign a certificate. It was in the interests of industry in the present crisis that there should be proper certification of illness causing absenteeism. Dr. A. C. Dawes (Smethwick) and Dr. R. S. Paton (Perth) also opposed the motion, the former saying that the Ministry of Labour certificate was an unnecessarily complicated document. The N.H.I. certificate and the private certificate were sufficient to meet all needs.

The motion was lost.

### The Dispensing Capitation Fee

Dr. Harrison (East Sussex) moved that in view of present-day costs the dispensing capitation fee was totally inadequate. Many practitioners in his area would prefer not to do dispensing, but it was forced upon them. So long as they had to do this work they expected an adequate fee. The cost of old-time medicines had gone up greatly since before the war, and the newer drugs such as the sulphonamides and others were very expensive.

Dr. Gregg said that in urban areas the payment made to chemists when worked out in terms of capitation fee was 5s. 6d., and in rural areas 5s. They had been informed—and were unable to dispute it—that the payment available for specially expensive drugs worked out at 3d. per insured person, and this, added to the dispensing capitation fee of 4s. 9d., gave an amount equal to that received by the rural chemist. Dr. J. R. Baker (Lindsey) said that for his own rural dispensing list of about 1,300 the new fee would recompense him adequately for the drugs he provided, though not for the cost of a dispenser, or the time spent in dispensing, or the cost of sending the drugs. He complained of the cumbersome methods of claiming for special drugs.

This motion also was lost.

A motion by Swansea, that the dispensing capitation fee should be on a sliding scale in view of the rising trend of dispensing costs, was met by a motion to proceed to the next business.

### The National Formulary

Dr. E. J. Allan (Derbyshire) moved to request the Council to consider the publication in the *British Medical Journal* of a series of articles devoted to the practical use of the *National Formulary*, 1947. He said that in the *Formulary* there were a large number of prescriptions difficult to understand. Many of the drugs had strange names: some were too new to be in the reference books, and certain of the pharmacological arrangements of the prescriptions required explanation.

Dr. Gregg said that it would be wrong to conclude that the present *Formulary* would be the one available in the new Health Service. At present a joint committee of the B.M.A. and the pharmaceutical societies was grappling with the problem

of devising a formulary. He thought the suggestion in the motion was a good one for a future occasion, but hardly worth while so far as the present *Formulary* was concerned.

The motion was lost.

### Chemists' Hours

Dr. J. Arthur (Northamptonshire) moved that the Ministry be requested to make arrangements to ensure that in every prescribing area at least one pharmacy was open for the dispensing of N.H.I. prescriptions during the evening surgery hours of local practitioners. Dr. Howie Wood (Isle of Wight) said that in many areas insured patients were getting a raw deal in this respect. Chemists in some towns had adopted an evening rota so that only one chemist was on duty. If a doctor asked permission of the insurance committee to omit his evening surgery, what would be said to him? In some areas such permission had been asked and refused. In his area the chemists were under an obligation to the committee to dispense urgent prescriptions, on which they were paid a double dispensing fee, if they resided on their premises, but in one town only one chemist did so.

Dr. C. G. Martin (London) spoke against the motion, feeling that the Ministry ought not to be brought into it at all. If they insisted that the chemists be open at certain hours, the Ministry might insist that doctors' surgeries should be open at certain hours also.

The motion was lost by a large majority.

### Reference of Patients to Specialists

Dr. Hayes (Bristol) moved to deprecate the practice of the Ministry in referring patients for specialists' opinions without reference to the patients' own doctors. If the Ministry declined to discontinue this practice the specialists concerned should be asked to consider the ethics of the matter.

Dr. Gregg said that while it was a proper thing to endeavour to make the position plain to the specialists it had to be remembered that in many instances the person to whom the patients were referred was the tuberculosis officer, who was not a consultant in the ordinary sense of the term but had certain obligations outside those of the ordinary consultants and specialists. The I.A.C. had tried to impress upon the Ministry that the proper way to deal with the slack practitioner was not to take responsibility away from him by instituting wholesale references in the Regional Medical Service, which was likely to make the slack practitioner more slack than ever, but to give him more responsibility.

An amendment by East Sussex to substitute the words "That this conference challenges the right of the Ministry of Health to override the ethical tradition of the medical profession" for "... deprecates the practice of the Ministry of Health" was accepted, and in that form the motion was carried.

### Rural Practice

It was agreed, again on the motion of East Sussex, to draw particular attention to para. 29 of the report of the I.A.C. concerning rural medical practice under the National Health Service. The mover, Dr. Harrison, said that the claims of rural practitioners should be given urgent consideration by the committee. The village might be the last stronghold of the real family doctor, to whom so much lip service was paid. Dr. Gregg assured the conference that the committee had the interests of rural practitioners very much at heart.

### Sickness Benefit in Pregnancy

Dr. Howie Wood (Isle of Wight) moved to express profound dissatisfaction with the refusal of the Ministry to accede to the request of the Insurance Acts Committee that where a doctor was satisfied that his patient would not be capable of work until after her confinement he should be allowed to issue a special intermediate certificate without waiting for the qualifying period of 28 days to elapse. Why should a woman during the last four weeks of her pregnancy be compelled to come to their waiting-rooms? If every practitioner were to adopt the suggested procedure and issue a special intermediate certificate the Ministry would soon alter its regulations.

Dr. A. Beauchamp (Birmingham) spoke to the same effect, and Dr. Gregg said that the committee was still pursuing the question with the Ministry.

The motion was carried.

### Postgraduate Courses for General Practitioners

Dr. W. H. Hayes (Bristol) asked the conference to express the opinion that doctors living within a short radius of large hospitals would best be kept up to date by constant attendance on their patients when they went to hospital for consultation or treatment. Special refresher courses were an inferior form of postgraduate teaching and should be reserved for those practising remote from teaching centres. He did not expect immediate action to be taken on this motion, but in the future a more satisfactory state of things might be achieved.

Dr. F. Gray (London) hoped the conference would look at this proposal carefully. Was it a practical proposition that all the doctors in large cities should be visiting their patients in the different hospitals? The mover had spoken lightly of extra pay—pay was to be based on the assumption of such service of mutual benefit to patient and practitioner. He was willing, apparently, to assume a tremendous obligation without any guarantee that practitioners would receive anything whatever for a great increase of work. Practitioners had their own job to do, for which they were specially qualified. Their job was to endeavour to cut short minor illness and to keep their patients healthy before they got to the hospital stage. They had sometimes been told, in quarters not very friendly to the general practitioner, that the only way to keep the general practitioner up to date was to see that he went into hospital and was under the supervision of specialists. That was unnecessary and untrue: they did their best work in their own surgeries.

Dr. S. Wand (Birmingham) said that many of them believed that the general practitioner should be in constant association with some kind of hospital at which consultants and specialists were in regular attendance. Whether the motion from Bristol would achieve this or not was a matter which need not concern them in too much detail, but the principle behind the motion was sufficiently good to justify further consideration by the I.A.C.

It was agreed to refer this motion to the committee, together with another from the same source, drawing attention to the inadequacy of short courses of study and expressing the view that a refresher course should be of at least three months' duration. The mover said that there was no slur on the general practitioner intended in the Bristol motion.

Dr. C. W. Marshall (Exeter) said that it was unfair and anomalous that the single-handed practitioner should receive from the Government a fee for a locum tenent when the practitioner was attending a postgraduate course, whereas the practitioner who had a partner or assistant received no such grant.

Dr. C. F. R. Killick (I.A.C.) considered that so long as the work of the practice was continued satisfactorily it was immaterial from the point of view of the Government whether it was done by a locum tenent or a partner, and the fee should be given as a right in either case. Dr. J. A. Ireland took another view. Considerable success had been achieved in getting a fee for a locum tenent granted by the Ministry, and he thought the matter should be allowed to rest there.

An Exeter motion "That when a practitioner attends a postgraduate course the fee for a locum tenent should be forthcoming from the Government as a matter of right" was carried by 75 to 53.

A motion by Swansea was also carried to the effect that the body promoting the postgraduate courses should arrange a panel of locum tenents from which a practitioner attending such a course might be able to secure suitable help while absent from his practice.

On a motion from the Isle of Wight para. 42 of the Annual Report dealing with recruitment of doctors and protection of practices was amended so that it read "... satisfactory arrangements of an *ad hoc* nature can and should be made for the protection of the practice of any doctor who is in need of such assistance." The words "can and should" took the place of the permissive "could."

Dr. D. F. Whitaker (Surrey) moved a resolution of congratulation to the I.A.C. on securing an increase in the capitation fee, the mileage fund, and the dispensing capitation fee.

The resolution was carried unanimously, and the report of the committee was then approved.

### ELECTIONS

It was announced that Dr. J. A. Brown was the only person nominated for the chairmanship of the conference, and he was accordingly re-elected.

The following were elected by the conference to the Insurance Acts Committee: Drs. A. Beauchamp, I. G. Innes, J. A. Ireland, J. A. Pridham, F. M. Rose, and W. Woolley.

Dr. C. G. Martin was elected to represent the conference on the Conjoint Committee of Epsom College, in place of Dr. J. G. Greenfield, who has represented the conference on that body for ten years and has now resigned. A vote of thanks was accorded to Dr. Greenfield for his services.

Dr. Brown, in returning thanks for his re-election, said that he did not know what form the conference would take next year, but whatever form it took he would endeavour to serve them as before.

### NATIONAL INSURANCE DEFENCE TRUST

Dr. J. W. Bone (Treasurer of the National Insurance Defence Fund) presented the balance-sheet. He said that up to the end of 1946 a sum of £325,500 had been accumulated. The actual sum was larger than this because the investments were shown at cost, and at the current market figure were worth perhaps £50,000 more. The amount received in subscriptions in 1946 was only £18,000, and this with dividends and interest gave a total income of £24,000—a position which he did not regard as entirely satisfactory.

A special appeal was made in February of this year, and since then the heartening total of £126,000 had been received. If that rate were maintained until July of next year the target of £1,000,000 would not, of course, be reached but they would be well on their way towards it. He drew attention to certain areas which had as yet paid only small percentages of their quota—what he referred to as scandalously small amounts. These defaulters were injuring the prospect of reaching the target. During the last five weeks a sum of just upon £41,000 had been received. In conclusion he expressed the opinion that they would want all this money—and very soon.

The accounts of the Trust were approved.

### MISCELLANEOUS MOTIONS

The conference proceeded to consider a number of miscellaneous motions from panel committees. One was from Bristol deprecating the fact that medical practitioners, as a profession, should have to certify that their patients were habitual smokers or snuff-takers. Certification should be limited on this and other forms to the witnessing of the signature of a person or patient known to them and not be regarded as a guarantee of his or her habits or desires.

Dr. S. Wand said that action on this matter had been already taken. He could not conceive how it should be expected that doctors should be in possession of information that old-age-pensioner patients were habitual smokers or snuff-takers. What was more important, however, was that they had to witness their signature, and many of these persons were confined to their homes and even to their beds, so that it was necessary to visit them for this purpose.

The Bristol motion was carried unanimously.

Dr. J. Beek (Glasgow) moved to instruct the committee to ask the Ministry to issue definite directives as to the procedure to be observed by new entrants seeking to obtain medical benefit and as to the issue of evidence of title to such benefit. Dr. A. Hamilton (Leicestershire) said that this difficulty appeared to arise particularly where the cards were received at the Post Office, not at the Labour Exchange. The remedy might be to give a postcard along with the card issued at the post office and to have this sent to the appropriate insurance committee. Dr. Gregg said that it would be desirable to obtain rather fuller knowledge about this than was available at the moment.

It was agreed to refer the matter to the I.A.C.

### Doctors' Cars, Telephones, Surgeries

Dr. A. Owen (Lancashire) had a motion pleading for effective priority for doctors in the supply of motor-cars, the Government to be asked to insist that this priority be given by the manufacturers, if necessary direct, and not through the usual agency channels. He said that, in the North of England at any rate, many doctors went about in cars which were not fit to be on the road.

Dr. S. Wand said that Headquarters was doing everything in its power on behalf of doctors without cars or whose cars were worn out. Dr. A. B. Davies (Walsall) said that they all appreciated the work done by the B.M.A.; the difficulty did not lie there. It was apparently necessary to satisfy a needs test before a doctor's name could be put down on the list at all. Certificates from garage people or others had to be produced that the existing car was not only unroadworthy but incapable of being made roadworthy. Many of them also had cars of old vintage and found difficulty in obtaining spares, which were often as important as new cars.

Dr. L. S. Potter (Assistant Secretary) said that such a resolution would assist the efforts he was making to convince the Ministry of Supply that there would be a breakdown in many parts of the country if this problem were not settled now. He had between 2,000 and 3,000 cases of urgency, and this number represented only about one-fifth of the orders outstanding from doctors. Technically in the list of priorities doctors, nurses, and midwives were second only to the police, but this did not work out in practice. An approach to the manufacturers was being made, and he would continue to do his best to keep in close touch with whatever seemed likely to be of help in this deplorable situation.

The motion was carried unanimously.

Dr. D. Saklatvala (West Bromwich) moved that the Government should be approached by the B.M.A. with a request that doctors should be free to use their cars without any limitations as to purpose, provided they were within a radius of 15 miles from their homes, special arrangements being made in the case of rural practitioners for a greater radius if necessary. He pointed out that members of the profession were continuously on call; they worked longer hours than other classes of the community, and their leisure time was tenuous.

Dr. Wand said that a meeting had taken place recently with the Permanent Secretary of the Ministry of Fuel and Power on this subject, and his reply was now awaited. He proceeded to argue that on this question of being at call doctors were in a completely different position from the members of any other profession or business.

The West Bromwich motion was carried unanimously, as was a further motion by Stoke-on-Trent declaring that as doctors had to maintain a twenty-four-hour service, and were on call throughout, they should be allowed to use petrol for social calls within a limited radius of their residences. Dr. Wand pointed out that in general the Ministry had agreed to the use of "E" petrol for scientific or divisional meetings.

Dr. Howie Wood (Isle of Wight) had a resolution that arrangements should be made whereby telephone messages could either be forwarded to a practitioner's deputy or suitably recorded when a practitioner's telephone was unattended. He said that a robot telephone device was offered for installation at a cost of £80 for each doctor if more than a hundred doctors agreed to take it, and he suggested that the supply of suitable apparatus might be financed through the Defence Trust. This was a matter which affected the health insurance service, and it was not reasonable to expect that, as now happened in many cases, either the doctor or his wife must constantly be available at the telephone.

Dr. Wand said that the General Practice Committee had taken up this matter, and a statement on the present position with regard to special apparatus and service would shortly appear in the *Journal*. It was possible in some areas to make arrangements locally for the taking of messages. He suggested that in all areas where it was desired to have some scheme of this kind an arrangement be made with the local post office. As for the suggestion that the National Insurance Defence Trust be asked to finance suitable apparatus, the first 5,000 applicants for the robot telephone would wipe out the Trust Fund entirely. Dr. Gregg said that it would be ridiculous to hold out any hope

of the attachment of any part of the funds of the Trust for a purpose of this kind. Dr. J. O. McDonagh thought that ill-considered, almost facetious suggestions of this kind were damaging at a time when an endeavour was being made to get contributions to the Trust Fund from backward areas.

Dr. Howie Wood withdrew the suggestion concerning the Defence Trust, and the general question of telephone service arrangements was referred to the Committee.

Dr. J. E. Darlow (Boston) moved to direct the attention of the I.A.C. to the fact that many practitioners used rented surgeries and that owing to lack of accommodation many such practitioners were threatened with considerable increases of rent. He suggested that the matter be referred to the Ministry of Health with a view to ensuring that practitioners did not suffer thereby. In one small town in his district there were ten doctors: two of them owned their own houses and practised there; one lived in a rented house where he practised, but the other seven practised in lock-up surgeries and found that rents kept going up.

Dr. W. Jope (I.A.C.) said that since the war started the capitation fee had been increased from 9s. to 15s. 6d., an increase conceded to some extent owing to the greatly increased cost of running a practice. Therefore he hoped the motion would not be accepted in its present form.

The mover withdrew the reference to the Ministry of Health, and as a reference to the I.A.C. the motion was carried.

### National Health Service Questions

A motion by Buckinghamshire was agreed to without discussion. It drew attention to the fact that the advent of penicillin and other drugs requiring frequent parenteral administration had increased the time spent by the insurance practitioner (especially the rural practitioner) in his practice, and that this should be borne in mind by representatives of the profession if and when discussions took place on the remuneration of the general practitioner in the National Health Service.

Dr. H. W. Pooler (Derbyshire) asked that in reaching agreement on the question of mileage allowance under the National Health Service the present system whereby rural practitioners are not allowed mileage for patients residing in urban districts should be abolished. A country doctor whose patient happened to reside in an urban area could not charge mileage fees, even if his residence was more than two miles from the residence of the patient, whereas an urban practitioner whose patient lived more than two miles out in the country was entitled to do so—an entirely inequitable position.

Dr. Cobb (York) said that if an urban doctor went out to a patient in the country, and that patient lived within two miles of a rural practitioner, mileage was not allowed. What was sauce for the goose was sauce for the gander. Dr. Gregg said that conditions in this respect varied in different areas.

A motion in the sense of the Derbyshire representation was agreed to, as a recommendation both to the I.A.C. and the Negotiating Committee.

### Representation on Health Committees

Dr. Talbot Rogers (I.A.C.) moved:

That in view of the desire of the Minister of Health for the close and continuous co-ordination of the local health authorities' services under Part III of the National Health Service Act, with the general medical services on the one hand and the hospital services on the other, the conference endorses the opinion that this co-ordination cannot be achieved unless the health committee includes proper representation of the medical profession in the area after consultation with the local medical committee.

He reminded the conference that it was laid down in the Act that every local health authority should establish a health committee, and that slightly more than half of its members must be members of the local authority. When these matters were under discussion before the Bill was introduced the Negotiating Committee took the matter up with the Ministry and pointed out that there had been disappointing previous experience of permissive powers given to local authorities. They were promised that, although it could not be put into an Act specifically, there would be a sufficiently strong directive from the Ministry to local authorities. The Minister of Health had carried out that part of his bargain, but his circular on the

subject had been completely ignored in many parts of the country, and health committees were being set up without any approach to anybody interested outside the membership of the council.

Dr. Gregg said that while it was true that the position was not as satisfactory as might be wished, it was better than many imagined. Out of 62 county councils, 42 had actually co-opted members of the medical profession on the health committee, and out of 83 county borough councils 55 had done so. Dr. J. A. Ireland (Shropshire) said that on his own county council there was only one medical member; she had been a member for three years, but had not yet been co-opted on the health committee. Dr. F. C. Cozens (Kent) said that his county council had prepared immunization and vaccination schemes without consultation with medical practitioners, and had been prepared to use health visitors for working the immunization scheme without any agreement with the doctors. The local medical committee should be consulted in the making of such schemes before they became public. Dr. F. H. Rose (Preston) said that some health authorities were evading their duty in this matter of co-option by offering membership of or consultation with some of their subcommittees. Such co-option should be refused unless there was co-option to the full committee. Dr. L. H. Wilson (Sheffield) and Dr. D. Saklatvala (West Bromwich) supported the motion.

Dr. Dain said that he came from a city which had completely refused to accept the Minister's directive, but a large proportion of authorities had done so, which made it the easier for the profession to insist that in the amending Act it should be made obligatory on councils to appoint medical members to their committee.

Dr. S. A. Forbes (Croydon) said that in his constituency they fought the battle ten years ago and got two members of the local profession co-opted on the local health committee. When the question arose as to medical representation on health committees under the new Act a cut-and-dried scheme was placed before the committee, which would have been accepted had it not been for the strong arguments of their representatives. The matter was referred to a subcommittee. At first it was suggested from the local authority side that there should be two medical members but with no voting power. This was argued out before the full health committee, and in the result the medical profession got three representatives on that committee, with voting power, and two representatives on every subcommittee who need not necessarily be members of the main committee. Altogether they might have a representation of ten to be chosen by the local medical committee. There was also an agreement that medical members should be appointed to every additional subcommittee, and that all schemes put forward by the local authority should be sent to the local medical committee for its observations before the local health authority considered them. (Applause.)

The Kent motion was carried unanimously, as also was a motion by Sheffield deploring the failure of many statutory authorities to appoint medical practitioners as members, and instructing negotiators to press for an amendment of the Act in this respect.

Dr. Talbot Rogers further moved that where a local health authority refused to use its powers of co-option the I.A.C. should take all practicable steps, centrally and locally, to ensure that proper medical representation was obtained. It might be suggested to the Minister that he should withdraw his approval of schemes of local authorities which were not constituted according to his directive.

Dr. J. H. E. Moore (Leeds) argued that no health authority was properly constituted unless it contained outside members. In section 19 the word "majority" was used (a majority of members of the local authority); if "majority" meant the greater part, it followed that there must be a lesser part without which the local health authority was not constituted. Dr. Talbot Rogers said that, unfortunately, "majority" might also be interpreted as 100% of the council, and councils which made no co-options were in their legal rights in so doing.

This motion also was carried unanimously.

### Purchase and Sale of Practices

On the motion of Dr. F. M. Rose (Preston) the I.A.C. asked to explore the possibility of preparing a scheme, with

thority to establish a special fund to finance the purchase and sale of practices, designed to eliminate the objections experienced in the past.

### Future of the I.A.C. and of the Conference

Asked by Burnley and Swansea about the future position of the I.A.C. and the conference in view of possible impending changes, Dr. Gregg said that such questions could be answered more or less as a matter of common sense. If it had been und necessary in National Health Insurance to have certain organizations, non-statutory but essential to the scheme, it could be found just as necessary under any extended scheme provision. He had no doubt that if the I.A.C. was replaced would be by a body of different name but composed to a great extent of the same people, elected, of course, by the whole profession. He believed that the new local medical committees could proceed to set up a body *vis-à-vis* the Ministry to look after their interests, and it would be impossible for such a body to operate successfully without something analogous to the present conference. With regard to the Defence Trust, its basis had been so framed as to be applicable to an extended service, and the same might well apply to funds accumulated by panel committees which had completed their quota and to certain benevolent trusts. The I.A.C. would make it its business to ensure a smooth transition with proper safeguards.

On a motion by Wallasey, that the Minister be asked to assure practitioners that accumulated funds in respect of insured persons under the new scheme who failed to exercise their right to select their doctor would be distributed to practitioners on a *pro rata* basis similar to that in operation under the present scheme, Dr. Gregg said that there was too much "if" in this solution. Those who did not want any private practice might ally themselves with it, but he thought he spoke for the great majority when he said they did not want private practice wiped out, and if there was to be private practice as well as public practice they must be very careful how they handled a matter of this kind.

It was agreed to pass to the next business.

### The Dain Fund

Dr. Dain expressed his pleasure at the adoption of the Dain Fund by the conference and by panel committees. A trust had been formed to help in the education of the children of doctors who were in economic difficulties owing to the death of the father or to family misfortune. Here was a form of charity which very properly belonged to them as doctors and which was worthy of extended support. Some very generous donations had been forthcoming from various areas. It had been decided that half of what was received should be spent as current income and half should go to increase the capital. During this year up to the end of September £581 had been received. He was grateful to the conference for taking it up and placing it on a bigger basis than at one time seemed possible.

The conference concluded with a vote of thanks to the chairman.

## PANEL CONFERENCE DINNER

The representatives who had attended the Panel Conference on Oct. 30 dined together the same evening at the Piccadilly Hotel, with Dr. J. A. Brown in the chair. After a day of oratory, speeches were at a minimum both in number and length. Dr. J. Beck, of Glasgow, proposed the health of the Insurance Acts Committee. Dr. E. A. Gregg's speech in response sounded rather like the swang song of the I.A.C., but in other respects it recalled the phoenix, for he was sure that the members of the new body, whatever name it might bear, would be much the same as of the old, and their spirit of devotion to the interests of the profession would be no less. Dr. S. A. Forbes proposed the health of the Chairman, and spoke of Dr. Brown's long service so quietly and effectively rendered, the soundness of his judgment, and his invariable courtesy. Dr. Brown, in reply, spoke up for that "hard-working, much abused, and grossly underpaid member of the community—the general practitioner." The general practitioner, he said, was not, as was suggested some years ago, a super-snooper for the

specialist, or the consultant's pet; he was doing a good job of work and with a great sense of responsibility. Dr. Brown mentioned some of the humours of practice—the remark, for instance, of the patient who had been listening to a radio play the night before which had a doctor as the principal character: "It was a lovely play—the doctor died." Through the enterprise of Dr. Jope a collection was taken at the tables for the Dain Fund, and realized £113—£14 more than last year. Dr. Dain thanked the members for this, a personal contribution—not from committees; and spoke again of the object of the Fund—the education of doctors' children orphaned or in reduced circumstances. The health of the Secretary and staff was toasted, and Dr. Charles Hill and Dr. Leslie Potter made suitable replies.

The evening was enlivened by the appearance of Gillie Potter, who described what they think in "Hogsnorton" of the new Health Act.

## SCOTTISH REGIONAL HOSPITAL BOARDS

The Secretary of State for Scotland announced on Oct. 30 the names of the members of Scotland's five Regional Hospital Boards. The appointments are as follows.

*Northern Regional Hospital Board.*—Mr. Donald Macpherson (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Col. the Hon. I. M. Campbell, D.S.O., T.D.; Miss M. B. Clyne; Mr. Robert Gilbert; Dr. Isaac H. Maciver; Rev. Father Neil MacKellaig; Mr. D. A. Plowman.

Appointed for the period ending March 31, 1951: Mr. A. J. C. Hamilton, F.R.C.S.; Rev. Ian M. MacRury; Mrs. Macleod of Macleod; Mr. Norman Robertson; Mr. Thomas Scott.

Appointed for the period ending March 31, 1952: Dr. John R. Anderson; Mr. John S. Banks; Mr. Norman MacIver; Mr. A. Mackintosh; Dr. William McWilliam; Mr. B. Soutar Simpson, F.R.C.S.Ed.

*North-eastern Regional Hospital Board.*—Mrs. May D. Baird (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Dr. A. Greig Anderson; Bailie W. J. L. Dean; Dr. D. G. Gordon; Mr. James Hay; Miss Bell Jobson; Mr. Fred Martin, C.B.E.; Mr. Robert Ollason.

Appointed for the period ending March 31, 1951: Prof. David Campbell, M.C.; Prof. John Cruickshank, C.B.E.; Rev. George A. M. Dickson; Mr. A. Fraser; Miss F. E. Kaye; Prof. D. R. MacCalman.

Appointed for the period ending March 31, 1952: Prof. R. S. Aitken; Capt. J. S. Allan, D.L.; Mr. James M. Burnett; Mr. J. Roy Campbell; Mr. Alexander Lyon, D.S.O., T.D., D.L.; Dr. Ian H. McCiure, O.B.E.; Mrs. Helen M. Taylor, M.D.

*Eastern Regional Hospital Board.*—Treasurer, Mr. William Hughes, O.B.E. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Dr. A. Allan Bell; Mr. John R. Christie; Mr. R. A. L. Duncan; Miss Ann S. Graham; Dr. James Lawson; Mrs. A. L. Matthew; Dr. J. D. Sagar.

Appointed for the period ending March 31, 1951: Provost William Coull; Mr. D. F. Craig, J.P.; Miss Margaret Fairlie, M.D.; Prof. Adam Patrick; Mr. Lewis F. Robertson, M.B.E.; Rev. A. Wylie Smith.

Appointed for the period ending March 31, 1952: Mrs. Agnes F. Allan, J.P.; Mr. T. M. Ferguson, O.B.E., J.P.; Prof. A. D. Hitchin; Mr. William O'Neill, J.P.; Mr. James E. Prain; Dr. G. Rankine; Mr. W. J. Ross.

*South-eastern Regional Hospital Board.*—Dr. James R. C. Greenlees, D.S.O. (chairman), who is appointed for the period ending on March 31, 1951.

Appointed for the period ending March 31, 1950: Mr. James Black, J.P.; Prof. J. C. Brash, M.C.; Miss J. J. Ferguson; Prof. Sir David K. Henderson; Mr. Ben McKay; Miss I. McNeill; Dr. Andrew Simpson; Miss E. Stirling; Sir Henry Wade, C.M.G., D.S.O.

Appointed for the period ending March 31, 1951: Mr. J. Allan; Bailie John G. Banks, J.P.; Dr. R. W. Craig, O.B.E.; Lady Fraser; Mr. R. K. Henderson; Prof. T. J. Mackie, C.B.E.; Miss M. C. Marshall, O.B.E.; Mr. David Martin.

Appointed for the period ending March 31, 1952: Mr. O. A. Cunningham, T.D.; Mr. W. P. Earsman, J.P.; Mr. I. Simson Hall, F.R.C.S.Ed.; Mr. W. F. T. Haulain, O.B.E., M.C., F.R.C.S.Ed.;

Sir Humphrey Broun Lindsay, D.S.O.; Mr. James McKelvie, J.P.; Prof. Sidney Smith, C.B.E.; Mr. John Sneddon; Major E. G. Thomson, M.C.

*Western Regional Hospital Board.*—Sir Alexander Macgregor, O.B.E. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Mr. J. Bruce Dewar, J.P.; Mr. James Finlay; Mr. R. McCracken; Mr. Andrew McGroarty; Miss L. D. F. McIntyre; Bailie S. P. McLaren; The Hon. Mrs. Maclean of Ardgour; Dr. Angus MacNiven; Mr. G. H. Stevenson, O.B.E.; M.C., F.R.C.S.Ed.; Mr. J. Stewart, J.P.; Dr. J. H. Wright.

Appointed for the period ending March 31, 1951: Mr. Lawrence S. Blanche; Prof. T. Ferguson; Rev. J. A. Fisher; Prof. C. F. W. Illingworth, C.B.E.; Mr. James Jack; Miss J. D. Jolly; Dr. George MacFeat, O.B.E.; Bailie A. C. Manuel, J.P.; Mr. George L. Peacock, J.P.; Mr. Joseph E. Russell.

Appointed for the period ending March 31, 1952: Mr. William Baxter; Mr. John Dunlop; Provost E. Fyfe, M.B.E.; Bailie Edward Lawson; Mr. Alex. S. MacLellan; Mr. Alexander Miller, F.R.C.S.Ed.; Provost C. Minihan; Mr. A. Moncrieff Mitchell; Mr. William Reid, J.P.; Dr. Alex. Watt; Prof. G. M. Wishart.

## MEDICINE AND THE CHURCH

### STATEMENT APPROVED BY COUNCIL

The Council has considered and discussed with representatives of the Churches' Council on Healing the relationship of doctor and priest or minister in connexion with their respective vocations and the ways in which their co-operation will be of service to the community. Leading a deputation to the Central Ethical Committee of the B.M.A., the Bishop of Croydon (now Bishop of Lincoln) gave a concise exposition of the principles and aims of the Churches' Council on Healing. He stated as a basic principle that the subject of healing should be approached from a threefold standpoint—body, mind, and spirit. These three aspects of the human being were so interdependent that successful treatment of disease in one was not possible without consideration of the others. With this conviction in mind the late Archbishop Temple set up a committee to correlate the activities of associations already in the field. The healing of "the whole man" was its main concern. The Archbishop's committee has now been established permanently as the Churches' Council on Healing. In its own words the Churches' Council on Healing "affords a recognized basis for the co-operation of doctors and clergy in the study and performance of their respective functions in the work of healing, and to promote this co-operation in thought and action throughout the country."

Inquiries have been received on the subject at B.M.A. Headquarters, particularly on the propriety of the association of doctors with clergy as unqualified persons who might be concerned with the treatment of patients. For this reason the Central Ethical Committee invited the Churches' Council on Healing to send a deputation to discuss the matter from every angle and to obtain information concerning its objects and methods. Subsequently the Central Ethical Committee met the Medical Advisory Committee of the Churches' Council.

From these discussions it has become clear that this body is doing valuable work and that there exists a field for legitimate and valuable co-operation between clergy and doctors in general and between the Churches' Council of Healing and the Association in particular. The Council of the B.M.A. is of opinion that there is no ethical reason to prevent medical practitioners from co-operating with clergy in all cases and more especially those in which the doctor in charge of the patient thinks that religious ministrations will conduce to health and peace of mind or lead to recovery. Such co-operation is often necessary and desirable and would help to prevent abuses which have arisen through the activities of irresponsible and unqualified persons. Among other reasons the Churches' Council on Healing exists to safeguard the interests of those people who might become the victims of so-called faith healers. Much harm has been done to individuals by unreasonable appeals to the emotions and by mass hysteria.

A central liaison has been established by the appointment of representatives of the Association to attend meetings of the

Churches' Council and *ex officio* to serve on its Medical Advisory Committee. It is considered that most useful work may be done by close personal contact between doctor and clergyman, with an interchange of views and active co-operation where possible. With regard to the co-operation which can be secured at a Divisional or parochial level, it is considered that arrangements can best be left to the B.M.A. Divisions acting in concert with any branch organization of the Churches' Council or similar body. Joint activities might include the appointment of and co-operation with hospital chaplains and their deputes, education of the public, and informal discussions between doctors and the clergy.

In addition to the above suggestions, which in some measure have already been the custom of doctors and clergy in different parts of the country, it would seem desirable that the whole field of medical practice in relation to the work of the Church should be explored. Moral aspects in the cause, treatment, and prevention of disease cannot be overlooked, and in this field also it is desirable that there should be fuller co-operation between Medicine and the Church working together should encourage a dynamic philosophy of health which would enable every citizen to find a way of life based on moral principle and on a sound knowledge of the factors which promote health and well-being. Health is more than a physical problem, and the patient's attitude both to illness and to other problems is an important factor in his recovery and adjustment to life. Negative forces such as fear, resentment, jealousy, indulgence, and carelessness play no small part in the level of both personal and national health. For these reasons we welcome opportunities for discussion and co-operation in the future between qualified medical practitioners and all who have a concern for the religious needs of their patients.

## Correspondence

### Working Hours in the N.H.S.

SIR,—Many letters have appeared in the *British Medical Journal* and articles in the Press about working hours in the National Health Service. They all stress the fact that the medical practitioner is grossly overworked under the present panel system, but by some strange process of reasoning the forecast regular hours, frequent week-end leave, holidays with pay, and attendance for postgraduate instruction under the National Health Service.

The average mixed general practice is composed of one-third N.H.I. patients and two-thirds private (or fee-paying) patients. When the National Health Service commences private practice will become severely restricted. All National Health Service patients will be entitled to medical advice without the payment of a fee and will consult their doctor far more often. Where there are now 30 or 40 patients in an evening surgery there will be 60 or 70. The number of visits will be greatly increased.

The medical practitioner in sheer self-defence will have to refer more patients to hospital out-patient departments, and the patients will also demand specialist opinion far more frequently. The present resources of the hospitals will be quite unable to deal with these increased numbers.

No, Sir; if the National Health Service is fully implemented in July, 1948, the result will be chaos.—I am, etc.,

Torquay.

GEORGE T. ALLINGTON.

SIR,—The recent correspondence on fixed duty hours quoted by Dr. Firman (*Supplement*, Nov. 1, p. 100) as a "flood" seems but a splash of clumsy propaganda for a full-time salaried State service with all the control and direction necessarily entailed. This writer claims that the genuine G.P.—and I understand genuine—sees relief in such arrangements from a life of slavery and believes that among the overwhelming number of representatives who voted against a motion for its introduction at the last A.R.M. there were no genuine G.P.s. Later in the letter he makes a cheap sneer by suggesting that anyway representatives could be only men with "better class" practices although perhaps I have mistaken his meaning of "better class."

As a G.P. with a large panel practice I cannot claim to have seen or to have felt a slave, unless to my own conscience, and would suggest that there is no need for slavery unless a practitioner takes on too much for his ability and fails to organize his relief through inefficiency or lack of personality. Through the last twenty years a vast number of general practitioners have organized group practice in the formation of partnerships which do not necessarily entail close financial commitments. Under such conditions the group of doctors with whom I work have managed to assure themselves of a free half-day every week, three Sundays free in every month, and a long week-end—i.e., mid-day Friday to Monday morning—at least once a month. Thus, it will be seen that small units of group practice can supply the needs of most doctors and at the same time give the patient a reasonable assurance of some degree of continuity of treatment, as members of the group soon realize the likes and dislikes of their colleagues for certain forms of treatment. The patient feels also that the visiting doctor is chosen by and is closely in contact with their own doctor and not any other doctor chosen by that remote body the "State."

Finally, let me remind Dr. Firman that no less than 17 ordinary genuine general practitioners are members of the Negotiating Body and that a special General Practitioner Subcommittee of the Negotiating Body was formed to discuss the articular problem of general practice with the Minister.—I am, etc.,

Waford, Herts.

A. STAVELEY GOUGH.

### Working Day in the Services

SIR,—Your correspondents F./O. (*Supplement*, Sept. 13, p. 66) and F./Lieut. (*Supplement*, Oct. 18, p. 92) are apparently mistaken in their conception of the duties of the Services medical officer. They are suffering from the same kind of error as a medical officer of health who, in addition to his normal duties, is charged with caring for the health of the town hall staff and who complains that looking after the health of a few hundred people does not keep him fully occupied.

It is true that they may have to see only three or four patients a day and that this will keep them occupied for only a very short time, but perhaps one may ask whether they have (a) satisfied themselves that the station water supply is pure and adequate; (b) done the same for milk and all other food supplies; (c) familiarized themselves with the job of every man on the station, and satisfied themselves that nothing can be done to improve the hygienic conditions under which it is done; (d) trained the entire station personnel in first aid; and perhaps one might venture to add (e) thoroughly trained themselves in the same subject; (f) satisfied themselves that the standard of hygiene in all cook-houses is adequate and the food cooked to the best advantage to preserve its nutritive qualities. This list could, of course, be considerably extended.

Medical officers called to the Forces, or at any rate to the R.A.F., are mostly required not to act as general practitioners but as practitioners of the allied art of keeping fit men fit. For a general practitioner to complain that his services are not fully utilized because he can only work as a general practitioner for an hour or so a day is precisely as reasonable as for a solicitor called to the Forces to complain that he has few opportunities to use his legal training.

Your correspondent F./Lieut. asks for a chance to work. I suggest that he applies himself to a few at least of the suggestions I have given or some of the many others he could certainly get from his commanding officer or his senior medical officer.—I am, etc.,

London, N.1.

R. E. W. FISHER,  
Wing Commander, R.A.F.O.

### War Service and Hospital Appointments

SIR,—I am a recently demobilized medical specialist and keenly follow the few advertised senior appointments. So I asked for the official application form for the vacant appointment of an assistant physician at a certain hospital. This is a very thorough questionnaire of two pages, asking a great many useful questions regarding day of birth, matrimonial status, whether R. practitioner, and if the present appointment is a B1 or B2 one. The appointment is a temporary one while the present holder will be away on military service. It seems, therefore, suitable to the council not to ask one question,

unimportant when filling such a vacancy: whether the applicant is an ex-Service medical officer or not.

While with the R.A.M.C. I did not regard the years spent in the Service as wasted. Even to-day, when balancing up, I feel I learnt more medicine than I forgot. I am only growing critical regarding the wisdom of having given up a safe E.M.S. appointment now, when seeing such (not by all means isolated) cases, which clearly show that war service is no additional qualification for hospital appointments. During the war we were repeatedly promised that all appointments would be filled only temporarily, thus offering at least an equal chance to serving M.O.s for the permanent appointments. We know that in too many cases that promise remained what Hitler once named a scrap of paper. But the appointment at that hospital and the conditions attached to it show too clearly the changed attitude. Not only will the job be reserved for its (probably very eminent) war-time holder, but, even when filling the temporary vacancy, war service counts for nothing.—I am, etc.,

London, N.W.11.

EX-SERVICE DOCTOR.

### 'Basic Petrol

SIR,—The letters from Dr. H. S. Pasmore (*Journal*, Oct. 18, p. 632) and Dr. C. E. Brown (*Supplement*, Oct. 18, p. 92) serve to confirm what I have suspected for some months now—that there has been something of a change of heart at the divisional petroleum offices. During the war I found the officers in charge of these establishments helpful, considerate, and sympathetically inclined towards the general practitioner. During the last three months, however, I have had two occasions to quarrel with the local office. The first was when I acquired a new car, which, like the old one, was in what we used in our ignorance and imperfect state of knowledge to call "the 8-h.p. class." Then I was informed, on applying for a transfer of the E coupons to the new car, that "as my new car was of lower h.p. than the old one" it would be necessary to reduce the allowance of "motor fuel" by some 33%. It took six weeks and three letters to make the petroleum officer understand that both cars were of the same h.p., a fact which had been stated by me at the outset.

The second occasion was at the beginning of the present ration period, when I was sent the usual circular about a 10% cut with the coupons, only to find that the amount was in the proportion of 66% of what I had applied for. Needless to say, I wrote back to the petroleum officer by return a rather strong letter, and within a week or two more coupons arrived. With these was a letter, the gist of which was that he had seen fit to increase my allowance. No apology was offered, no explanation given.

In consequence, Sir, I feel with Dr. Brown that it is now time for some kind of revolt against this dictatorship and petty bureaucracy. Perhaps the B.M.A. could collect evidence such as Dr. Brown's and my own with which to support a protest to the Ministry of Fuel and Power?—I am, etc.,

Newcastle-upon-Tyne.

L. R. ATKINSON.

SIR,—It is to be hoped that letters such as that of Dr. Charles E. Brown (*Supplement*, Oct. 18, p. 92) will provoke the B.M.A. into making a firm protest. When I applied for my current allowance, I pointed out that for the last two winters I had had to expend my basic ration on the practice in order to keep going till the end of the rationing period. No acknowledgment was received, and my allowance was cut by 33%.—I am, etc.,

Wolverhampton.

PHILIP W. G. BAXTER.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils.*—Barnsley, Gateshead.  
*Metropolitan Borough Councils.*—Fulham, Hackney, Poplar.  
*Non-County Borough Councils.*—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallend.  
*Urban District Councils.*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.  
*Scottish Burghs.*—Motherwell and Wishaw.

## H.M. Forces Appointments

### ARMY

Colonel R. A. Hepple, C.B.E., M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.  
Lieutenant-Colonel J. W. Hyatt, from R.A.M.C., to be Colonel.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. McP. MacKinnon has retired on retired pay and has been granted the honorary rank of Colonel.  
Major (War Substantive Lieutenant-Colonel) J. P. Douglas, O.B.E., to be Lieutenant-Colonel.

Majors H. K. G. Nash and H. Clain to be Lieutenant-Colonels.  
War Substantive Major J. G. S. Holman, M.C., to be Major.  
Captain A. C. S. Hobson, M.C., to be Major.  
Captain T. A. Groves has retired and has been granted the honorary rank of Major.

*Short Service Commission, Specialist*.—War Substantive Captain D. G. Milne, from R.A.M.C., Emergency Commission, to be Captain.

*Short Service Commission*.—Captain T. C. R. Archer has been appointed to a permanent commission.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain R. Hertz has relinquished her commission and has been granted the honorary rank of Captain.

To be Lieutenants: Rebeka Hamlyn and Jean T. Smith.

### COLONIAL MEDICAL SERVICE

The following appointments have been announced: P. A. Ailsopp, M.R.C.S., L.R.C.P., Medical Officer, Malaya; D. Currie, M.B., B.Ch., Medical Officer, Tanganyika; B. C. Hillary, M.B., B.Ch., Lady Medical Officer, Malaya; J. Littlejohn, L.R.C.P.&S.Ed., Medical Officer, Kenya; J. J. O'Dwyer, Medical Officer, Nigeria; J. J. Talbot, M.B., B.Ch., Medical Officer, British Guiana; G. M. Thomson, M.C., M.D., M.R.C.P., Adviser on Venereal Disease Control, West Indies; E. J. Blackaby, M.R.C.S., L.R.C.P., Senior Medical Officer, Uganda.

## Association Notices

### Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

### Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research and record in general practice; it includes a money award of value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previous published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on the results, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, nor a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. The prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded must, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,  
Secretary.

### B.M.A. LIBRARY

The Association's Library is being transferred from its present accommodation in the main building at B.M.A. House to the first and second floors of the Garden Court wing. To facilitate the removal the Library will be closed until 9.30 a.m. on Monday, Nov. 17.

### Branch and Division Meetings to be Held

**AYRSHIRE DIVISION**.—At Heathfield Hospital, Ayr, Sunday, Nov. 10, 7 p.m. Lecture by Dr. J. H. MacDonald.

**EAST HERTS DIVISION**.—At Lister Hospital, Hitchin, Wednesday, Nov. 12, 9 p.m., joint meeting with South Bedfordshire Division. Address by Dr. P. J. W. Mills: Recent Views concerning the Treatment of Hypertension.

**REIGATE DIVISION**.—At Redhill County Hospital, Redhill, Tuesday, Nov. 11, 8.30 p.m. Mr. Dickson Wright: The Surgical Treatment of Hypertension.

At the end of July Dr. William Peach Hay celebrated the fiftieth anniversary of starting medical practice at Peterborough, the occasion being honoured when his medical colleagues entertained him to dinner on Sept. 24. A native of Arbroath, Dr. Peach Hay qualified in the University of Edinburgh in 1891, after having already been on a whaling expedition. Various postgraduate appointments were followed by a period in Lagos with the Colonial Medical Service. It was on July 31, 1897, that he started practising at Peterborough. A keen lover of the theatre, a skilled metal- and wood-worker, and an excellent shot, Dr. Peach Hay has put in much work for the Peterborough and District Memorial Hospital, was the first and only chairman of the Soke of Peterborough Insurance Committee, and has actively supported the B.M.A.

LONDON SATURDAY NOVEMBER 15 1947

## THIOURACIL IN TOXIC GOITRE

A REVIEW OF FOUR YEARS' EXPERIENCE

BY

HAROLD COOKSON, M.D., B.Sc., F.R.C.P.

AND

F. H. STAINES, M.R.C.S., L.R.C.P.

*Supernumerary House-Physician, Cornelia Hospital, Poole*

The widespread clinical trial of thiouracil and its derivatives in toxic goitre since 1943 has shown that they are very effective in reducing the excessive thyroid secretion of this condition. A partial answer can now be given to those questions which naturally arose as to the value of these antithyroid drugs compared with other methods of treatment. The first question was whether or not thyroid function would remain normal after the drug was discontinued, and how long it would be necessary to give the drug before it could be discontinued. Equally important were the nature and the frequency of toxic effects and how, if at all, they were to be avoided. Thirdly, were there any particular age groups or clinical types for which thiouracil was especially suitable or contraindicated? The answers to these problems would of course decide the place of thiouracil in relation to other methods of treatment, thyroidectomy in particular.

With regard to remissions, Beierwaltes and Sturgis (1946a) noted eight in 45 cases; the course of thiouracil had averaged 10½ months in the eight cases, and the duration of the remission (to date) was from 3 to 12 months. Their cases of nodular goitre were not treated by thiouracil but by thyroidectomy. Himsworth *et al.* (1947) noted 25 remissions in a total of 65 treated, lasting from 6 to 30 months and over; only two had not relapsed after a remission of 18 months or more. Nussey (1946) reported 16 patients out of 50 with remissions of 5 to 17 months, and Wilson (1946) had two patients in a series of 65 who had not relapsed after stopping thiouracil for over a year. Williams *et al.* (1947) gave details of 111 patients who had stopped thiouracil. Of these, 51 had remissions lasting from 3 to 31 months—44 for over a year and 33 for more than 18 months; of all their patients who remained well for more than a year without treatment only one had a relapse. It would appear that this series of 111 cases is about one-third of the total number of their thiouracil-treated patients.

With regard to the length of treatment, Himsworth *et al.* (1947) concluded that prolonged treatment (a year or more) was less likely to be followed by relapse than when it was short—that is, less than one year—but the cases reported by Nussey (1946) showed a longer average remission with treatment for less than six months than when it had exceeded this time. The 111 patients of Williams *et al.* (1947) received thiouracil for an average of 10 months; they did not find a close relation between the length of treatment and the length of remission.

Toxic effects occurred in about 13% in the survey of Van Winkle *et al.* (1946) covering nearly 6,000 cases. This figure is based on collected results from a large number of observers and has not the same value as personal observation. It includes many cases of leucopenia which was diagnosed when the total white count was less than 4,000, and some of these may have been normal counts for the individuals concerned. Drug fever in this series had an incidence of 2.7%; in Moore's (1946) collected cases this was about 5%. The incidence of agranulocytosis (granulocytopenia) in these two series was a little over 2% and the mortality about 0.5%. From these inquiries it did not seem that the higher doses of thiouracil were more likely to cause agranulocytosis, but the range of dosage was higher than that generally used to-day. Some skin eruptions are not infrequent, but apart from urticaria they do not usually require the permanent stoppage of the drug. The above are the common and important reactions, though there are others of less significance. Many diverse and almost solitary conditions have been reported as complications of thiouracil, not always with proof that they are not intercurrent and unconnected with the drug. So far as is known at present thiouracil and its methyl derivative are the least toxic antithyroid drugs (Morgans, 1947). Propyl thiouracil may be better, but so far there is no proof. Ergothioneine (Lawson and Rimington, 1947) is under trial.

The applicability of thiouracil to different types has to be considered. Some authors have suggested that it is less effective when the thyrotoxicosis is secondary and the goitre is nodular than when it is smooth (Grainger, Gregson, and Pemberton, 1945). There is really no sharp differentiation between these two types, one merging insensibly into the other as the goitre increases in age. The goitre which is quite smooth is relatively rare, and the great majority are more or less nodular. On the other hand, Williams *et al.* (1947) had results equally good in nodular goitres, and indirect evidence on this point is the ability of thiouracil to stop auricular fibrillation and restore normal rhythm, this arrhythmia occurring usually in the older patients with nodular goitres (Nussey, 1944; Cookson, 1945; Williams, 1946; Himsworth *et al.*, 1947; Wilson, 1946; Wilson and Goodwin, 1947). Neither iodine nor external x-ray treatment will accomplish this, and it has yet to be shown what radioactive iodine will do in this respect. In pregnancy resistance to thiouracil has been reported (Cookson, 1947) and it has been recorded that thiouracil may cause goitre

the foetus (Davis and Forbes, 1945). But it has been used successfully without detriment to the foetus (Eaton, 1945; Strouse and Drabkin, 1946; Davis and Forbes, 1945; Williams *et al.*, 1947).

When the goitre is very large or when it is producing symptoms of tracheal pressure it is generally considered that removal is indicated rather than thiouracil.

In children thiouracil might be very suitable for the treatment of toxic goitre as it is difficult to estimate the amount of thyroid tissue to leave when doing thyroidectomy. Enough must be left to meet the needs of a growing child, yet not so much as to cause persistence of hyperthyroidism. With thiouracil it should be possible to adjust the dose to meet these requirements. Beierwaltes and Sturgis (1946b) used thiouracil in the case of a 14-year-old girl and would appear to have obtained a satisfactory result in that her B.M.R. was reduced from +61% to -3%.

### Results of Thiouracil Administration

Our results of the treatment of 95 cases of toxic goitre with thiouracil or methyl thiouracil are based on observations extending from 1943 to 1947. The age and sex distribution and the numbers of smooth and nodular goitres are shown in Table I. Men accounted for only five of the

TABLE I.—Age and Sex Distribution

70-79 ..	4	—	—	5
81 ..	1	—	—	1

eases and there were only 10 goitres which could be described as smooth. Three of the patients had hyperthyroidism, with goitre and ocular signs, after taking thyroid extract, which in two had been prescribed for obesity. Thyroidectomy had previously been carried out in seven at intervals of from 6 to 26 years before, and one other had had x-ray therapy. In eight patients, after having a course of thiouracil, thyroidectomy was done for a variety of reasons. These reasons were: toxic reaction to the drug (granulopenia) in one, tracheal pressure in two, haematoma of the thyroid in one (possibly a thiouracil effect), one with a large goitre which did not respond to thiouracil, and three chose to have operation though their response to thiouracil had been good. Death from various causes occurred in 10 cases: three from thyroid toxæmia, with heart failure, respiratory infections, and mental symptoms, within eight weeks of starting thiouracil; one after cerebral thrombosis; one from coronary thrombosis; two ambulant cases with auricular fibrillation died suddenly; one developed mental symptoms and went into coma; one died probably from agranulocytosis; and one from recurrent heart failure after showing a good response for six months.

The initial dosage of the drugs used in the first year or two of the period of investigation was 1 g. to 0.6 g. daily, but this has gradually been reduced and the initial dose is now nearly always 0.1 g. three times daily and never exceeds 0.1 g. four times daily. Once hyperthyroidism has been controlled a maintenance dose of from 0.059 g. daily to 0.1 g. three times daily is used—generally 0.1 g. daily. Resistance to thiouracil—that is, persistence of hyperthyroidism after several weeks' or months' treatment—was noted in six cases: three with very large goitres, estimated at 10 or more times the normal in size; a case of pregnancy; a woman aged 81 with auricular fibrillation and congestive

heart failure; and one case in which hyperthyroidism persisted after the administration of thyroid extract.

The periods of observation and treatment were as follows: less than 6 months, 39 cases; 6 to 12 months, 1 cases; 1 to 2 years, 17 cases; 2 to 3 years, 16 cases; over 3 years, 6 cases. In 40 patients there were remissions (periods with no signs or symptoms of hyperthyroidism) during which no thiouracil was given (Table II). In case

where more than one remission has occurred only the longest is considered. These remissions lasted from 2 to 25 months. Relapses have occurred in 15. Of 10 patients with smooth goitres, whose average age was 29, eight had remissions lasting from 6 to 25 months, and of the two remaining one has relapsed and the other was treated by thyroidectomy after thiouracil had produced toxic effect. The 85 patients with nodular goitre, having an average age of 51, showed 31 remissions—6 (7%) of more than 1 year and 13 (14%) of more than 6 months. Of the 31 cases 1 have relapsed. Two are in excellent health, having taken no thiouracil for 2 years or more. There was no proportional relation between the occurrence or length of remissions and the duration of treatment. In 11 cases with remissions of 12 months or longer the duration of treatment averaged 8 months, with extremes of 4 and 17 months. In 29 cases with remissions lasting less than 12 months the average duration of treatment was 8 months with extremes of 2 and 25 months. During remissions the goitre has usually decreased in size and in three cases has even become impalpable. Temporary enlargement sometimes occurs early in treatment, but reduction in the dose of thiouracil relieved this. An adequate dose could be found which effectively controlled symptoms without causing further thyroid enlargement. The same result was achieved in a few by the addition of a small amount of thyroid extract—1/4 gr. to 1 gr. (16 to 65 mg.) daily—the dose of thiouracil being maintained. Whether or not this has any advantage over the simple reduction of the thiouracil dose is uncertain.

Seven patients who previously had thyroidectomy also responded rapidly and very satisfactorily to the drug, but only two have shown remissions in spite of treatment lasting on the average 18 months.

### Effects in Auricular Fibrillation

Thiouracil was used in 15 cases of thyrotoxic auricular fibrillation—14 women and 1 man, whose ages ranged from 43 to 81. In addition there were one woman who also had mitral stenosis and one case of paroxysmal fibrillation. Normal rhythm returned in 8 of 16 cases as a result of thiouracil administration lasting from 4 days to 15 weeks, with an average, excluding these two extremes, of 35 days. Four of these had congestive failure, which cleared up rapidly and in three has not returned. In the patient with paroxysms of auricular fibrillation the attacks had been frequent before treatment was begun, but thereafter she had only three attacks within the first month and none during the subsequent four months of observation. One other case, that of a woman of 72, first came under observation with toxic goitre and normal rhythm, rate about 100 per minute, and a high pulse pressure (175/0). There

was nothing in her history to indicate the occurrence of paroxysmal fibrillation, but after taking methyl thiouracil, 0.3 g. daily for 11 days, fibrillation developed. The drug was continued in the same dose, and 12 days later normal rhythm, rate 84 per minute, was recorded.

In eight cases thiouracil failed to restore normal rhythm. One of these patients was moribund when treatment was started, and death occurred on the sixth day; a second, aged 81, died after two months of thiouracil, which had not been given continuously because of toxic effects. Two ambulant patients dropped dead after two to three months of therapy, having responded fairly well apart from the persistence of the arrhythmia; one had mitral stenosis; and three had large retrosternal goitres. One patient with a large goitre who had thyroidectomy after showing resistance to thiouracil for over twelve months developed a short paroxysm of auricular fibrillation two days after the operation.

### Toxic Reactions

Symptoms or signs suggesting toxic effects were present in 26 patients, but after various steps had been taken to prove which of these symptoms were in fact due to the drug, such as a period of interruption or substitution, 12 were excluded, giving an incidence of 14 genuine reactions. In only two was it necessary to stop the drug permanently because of the reactions it produced. The incidence of reactions was about the same with thiouracil and methyl thiouracil (13% and 11% respectively). In addition there were two patients who showed adverse effects with both drugs. On the other hand, methyl thiouracil was well tolerated by four patients who had suffered ill effects from thiouracil. Of 64 cases under treatment with the thiouracils in the past 12 months only six have developed toxic reactions, and only one has been observed in the past six months.

Table III shows the nature of the toxic effects, consisting mostly of rashes, swelling of face, eyelids, and feet, sore

TABLE III.—Toxic Reactions

throats, and neck and head pains. The drug was given up in two cases—one because of the occurrence of iritis and one because of granulopenia. Case 13 probably had agranulocytosis—the only one in the series. In the eighth week of treatment and while taking 0.2 g. of thiouracil three times daily she developed sore throat and diarrhoea. Her own doctor saw her two days later, when she was found to have tonsillitis, pyrexia, and tachycardia, and death occurred suddenly on the fifth day of the acute illness. One further patient not included in Table III, who had a very

large goitre and was being prepared for operation, developed an upper respiratory infection. She died in the eighth week of treatment. A severe pulmonary oedema was found at necropsy, and in the absence of a cardiac lesion to explain this the possibility of its being a thiouracil effect must be considered, as Drinker (1945) has shown that a thiourea derivative is able to cause pulmonary oedema in dogs when injected intravenously.

The duration of the treatment before the occurrence of toxic reactions varied widely from 8 to 87 weeks (Table III), with total previous doses of from 9 to 120 g. Reaction came no earlier when the initial dosage had been high (over 0.5 g. daily) than when it had been low (less than 0.5 g. daily). At the time of the reaction 4 patients were taking 0.1 g. daily; the other 10 were taking 0.2 to 0.4 g. daily.

### Illustrative Cases

**Case 1.**—Mrs. B. P., born 1867. (Figs. 1 and 2.) An earlier report of this patient has been given (Cookson, 1945); before treatment in 1944, weight 70 lb. (31.75 kg.); previous weight, 140 lb. (63.5 kg.). Improved rapidly on thiouracil; has taken thiouracil up to the time of writing (July, 1947), except for several periods of two months when it was discontinued. In excellent health. Maintenance dose, 0.1 g. daily. Present weight, 109 lb. (49.5 kg.). Pulse rate, 74. The small nodular goitre originally present is no longer palpable.

**Case 2.**—Mrs. B., born 1894. First seen August, 1944; nodular goitre; tremor of hands; pulse rate, 140 regular; B.P., 160/80; B.M.R. before treatment, +51%; after four weeks' treatment, +11%; after six weeks' treatment, -6%. Symptoms disappeared on thiouracil, which was continued for ten months; weight increase of 24 lb. (10.9 kg.); pulse rate, 70 per minute; feeling very well; goitre smaller and softer. July, 1947: weight stationary; pulse rate, 64 per minute; goitre smaller; patient feels very well; no thiouracil for two years.

**Case 3.**—Mrs. C. G., born 1882. First seen March, 1945; rather large cystic goitre; auricular fibrillation, ventricular rate, 156 per minute in spite of digitalis; B.M.R. before treatment, +35%; after three weeks' treatment, +15%. On the 25th day of thiouracil administration normal rhythm returned; thiouracil continued since except for two periods of a few weeks. Condition good and cardiac rhythm normal—rate about 70 per minute; goitre smaller. Total period of thiouracil administration, 28 months.

Fig. 1.—Case 1, woman aged 77. September, 1944, before treatment with thiouracil.

Fig. 2.—Same patient as Fig. 1, after 77 months almost continuously on thiouracil; aged 80; quite well and active.

### Discussion

The results show that thiouracil controlled the hyperfunction of the thyroid in all but six of 95 cases of toxic goitre. This control was maintained so long as the drug was continued. Further, in 40 cases there were remissions—that is to say, it was possible sooner or later to stop the treatment without the recurrence of symptoms over a period of two months or more. The time to stop thiouracil was judged by the response to treatment. If the dose can be progressively lessened, say, to 0.05 g. or less daily, and yet weight is still being gained and the pulse remains slow, indicating that thyroid function is on the low side of normal, the final step of discontinuing the drug may be taken. Although thiouracil was found to be effective in both the nodular and the smooth forms of toxic goitre the proportion of remissions was much higher in the smooth type. Relapses were noted in 15 of the 40 patients with remissions, but they were then readily controlled again with the drug. Later a second and even a third remission might occur in the same patient. The longest remissions observed were of a little more than two years—one in a woman with smooth goitre, and the other in a case of nodular goitre. Both are in excellent health and having no treatment whatever.

The six instances of failure of thiouracil to control thyrotoxicosis were accounted for by elderly cases with advanced cardiovascular changes and mental symptoms, by very large goitres, by one case of pregnancy, and by one patient in whom persistent hyperthyroidism appeared to have been induced by thyroid extract. Nevertheless a good result with thiouracil was seen in one patient with a very large goitre, who after two years' treatment had a remission which has now lasted 12 months.

Toxic effects were seen in 14% of cases, but in only two was it necessary to abandon the drug on this account. Agranulocytosis was almost certainly the cause of one death that must be attributed to the drug. With strict supervision, as practised now, this might have been avoided. The results showed little to choose between thiouracil and methyl thiouracil as a cause of toxic reactions, though occasionally methyl thiouracil was well tolerated after thiouracil had produced a reaction. Most toxic effects were seen when the daily dose exceeded 0.1 g. daily, and the incidence of these effects had declined in the past year or two concurrently with the use of lower doses. A further observation on thiouracil reactions was that their incidence was much higher when the drug was used in cases of slight or doubtful toxicity. None of these cases is included in this review.

Thiouracil is effective with occasional exceptions in all forms of toxic goitre, the only absolute bar to its use being the existence of tracheal pressure or any suspicion of malignant change. With a large goitre the drug may fail in its purpose, but in any case the patient with such a goitre would be well advised to have operation. In the elderly—say past 60—when toxic goitre has often produced auricular fibrillation, perhaps with cardiac failure, thiouracil was found suitable as the sole treatment. These changes must not be too advanced, however, for they are then irreversible, and there may not even be time for the drug to exert its effect. In one other group thiouracil was also particularly useful—that is, in young subjects with smooth goitres of moderate size. Here remission is probable, and this may be accompanied by the disappearance of the goitre itself.

The main handicap of this form of therapy is now not the hazard of serious toxic reaction but the length of treatment and the constant supervision which is necessary while this is in progress. This supervision is essential both for

the adjustment of the dose, which is frequently necessary, and for the recognition of any adverse effects. A term cannot yet be put to the length of treatment. In a high proportion it is a year or two and may be even more, and remissions when they occur are often of limited duration. In spite of these drawbacks, however, there is no doubt that the antithyroid drugs now available have established themselves as a most valuable addition to the methods of treatment of toxic goitre, and in certain types as the method of choice.

### Summary

The effects of thiouracil and methyl thiouracil in 95 cases of toxic goitre have been investigated over the period 1943-7. These drugs controlled the disease in all but six cases.

In 40 patients there were remissions lasting from 2 to 25 months; 15 of these have so far relapsed. A higher proportion of remissions occurred when the goitre was smooth than when it was nodular.

Toxic reactions were observed in 14 patients. Agranulocytosis was probably responsible for the death of one patient.

Thiouracil controlled the hyperthyroidism of nodular goitre, and in 8 of 15 instances of auricular fibrillation normal rhythm was restored. In one other case with paroxysms of fibrillation the attacks ceased.

Thiouracil produced its best results in toxic goitre in elderly patients and in young subjects with a smooth goitre of moderate or small size.

Mr. J. Lyle Cameron, speaking on "The Care of the Mother" at the Royal Institute of Public Health and Hygiene on Oct. 22, said that the care of the mother really began as soon as the mother-to-be was born. A word must be said about the upbringing of the little girl—a duty which fell first and foremost upon the parents and not upon teachers or institutions. It was well to teach the naturalness of life and of all bodily functions. It was much better that the growing person should learn of such matters in a practical way from a parent than to hear them whispered archly by some older companion. Early instruction in sex matters was altogether a good thing. It should in no way run contrary to primitive modesty, which was a protective instinct and could indeed be characteristic of considerable charm. There was another point regarding health that was to be considered from a national point of view. To-day, under the stress and strain of very unsound economics, so many women were worried and suffered from anxieties. This had been very noticeable during the war, and actually seemed to be on the increase since post-war conditions had overwhelmed us. This state of affairs was quite apart from the diet and many insufficiencies in food varieties. The question might be asked: Should an expectant mother go out to work, either in a factory or other places of employment? It was quite safe, and could be in the best interests of her health, provided that the work did not entail strenuous exertion and that it provided a sufficiency of exercise. The expectant mother's home life must not be deranged or invaded by anxieties and, especially, disconcerting duties as a result of her work outside. She must be happy in her work and at the same time happy in her home.

## MALNUTRITION OF THE NERVOUS SYSTEM\*

BY

W. RUSSELL BRAIN, D.M., F.R.C.P.

*Physician to the London Hospital and the Maida Vale Hospital for Nervous Diseases*

What is meant by malnutrition of the nervous system? The most obvious example is the deficiency in the food of some substance necessary for the maintenance of normal nervous activity, and it is with this that I am here mainly concerned. But clearly malnutrition means much more than this. The food may be adequate but its absorption from the alimentary canal may be defective; or, though it is normal in amount and quality and normally absorbed, some metabolic disorder may interfere with its utilization or some local lesion may prevent it from reaching the nervous tissues. At one extreme dietary avitaminosis, at the other cerebral thrombosis, are causes of malnutrition of the nervous system, and between the two the distinction between disorders of nutrition and metabolism is by no means clear. But I am not here concerned with local lesions or metabolism, though neither must be altogether lost to sight. For the present purpose malnutrition may be defined as a failure of the nervous system to obtain substances necessary for its maintenance and activity as a result of defective diet or defective absorption from the alimentary canal.

If we list the food substances presumably necessary for the nutrition of the nervous system—proteins, fats, sugar, vitamins, and minerals—the large gaps in our knowledge at once become apparent. Concerning the need of the nervous system for proteins and amino-acids we know almost nothing, though recent work (Zimmerman and Ross, 1944; Albert and Warden, 1944; Weil-Malherbe, 1935) suggests that glutamic acid may be especially important for cerebral metabolism. In particular we do not know what part, if any, defective protein intake plays in causing deficiency syndromes. We know even less about the role of lipoids and mineral substances, though copper plays some part in the prevention of sway-back in sheep. Almost all we know is concerned with the metabolism of glucose by the nervous system and the part played in this by certain vitamins of the B group. Here it is worth remarking that man has taken over from the vegetable kingdom not only these vitamins but also their role in metabolism. Both aneurin and nicotinic acid are present throughout the vegetable kingdom, in plants, bacteria, yeasts, and fungi—aneurin being necessary for the breakdown of pyruvic acid, and nicotinic acid acting as a component of co-dehydrogenase (Schopfer, 1943). Indeed, these vitamins play so narrowly specific a part that they would be useless to us if our nervous systems did not metabolize carbohydrate in the same way as the plants. Moreover, we are doubly dependent upon the vegetable kingdom, for we consume the vitamins that the vegetables synthesize, and, in addition, bacteria in the intestine may be a substantial source of these vitamins by generating them *in situ* (*British Medical Journal*, 1945, 1, 879).

### Aneurin Deficiency Beriberi

The view that beriberi might be due to a lack of more than one factor seems to have been disposed of by experimental work and by the observation of the correlation between the incidence of beriberi and the aneurin/non-

fat-calorie ratio first noted by Williams and Spies (1938). This is well shown in the observations of Burgess (1946) upon prisoners of war. When the aneurin/non-fat-calorie ratio was above 0.3 beriberi was almost absent; when it fell below that figure the incidence of beriberi varied inversely with it (Fig. 1). But, as Walshe (1917-18) has

FIG. 1.—Monthly incidence of beriberi compared with estimated total calories and vitamin B<sub>1</sub>/non-fat-calorie ratio of diet at Changi Camp (Burgess, 1946).

pointed out, aneurin is not an antineuritic factor in the sense that it is necessary for the nutrition of the peripheral nerves, and all the evidence favours his view that the polyneuritis in beriberi is caused by an intoxication with pyruvic acid and allied intermediate products of sugar metabolism, which is incomplete owing to lack of aneurin. Hence the importance of the aneurin/non-fat-calorie ratio, for beriberi will not occur in the absence of sufficient carbohydrate to metabolize into pyruvic acid. It has been suggested that diabetic polyneuritis may be due to aneurin deficiency (Rudy and Epstein, 1945), but this is unlikely, for the diabetic whose tissues cannot utilize sugar normally is in the position of a patient with a high aneurin/non-fat-calorie ratio, and Lowry and Hegsted (1945) have shown that rats rendered diabetic with alloxan require less aneurin than normal animals and show no greater tendency than controls to develop symptoms of aneurin deficiency on a defective diet.

The role of aneurin deficiency in alcoholic polyneuritis is still debatable, but the observations of Brown (1941) that a group of patients given additional aneurin recovered no more quickly than a control group on a hospital diet is surely not evidence against it. Leaving on one side the question whether the two groups were comparable, there is no reason to suppose that aneurin promotes the regeneration of damaged peripheral nerves or that it can do more even in beriberi than put an end to the intoxication of a perverted sugar metabolism. The patient whose alcoholism and gastritis are treated and who is given a full and balanced diet is therefore likely to recover, even if his polyneuritis is due to aneurin deficiency, as quickly as one given excessive doses of aneurin. For somewhat similar reasons diphtherial polyneuritis fails to respond to diphtheria antitoxin. It is well known that aneurin will not lead to full recovery in chronic beriberi, probably because, as Wright (1903) showed, in severe beriberi the posterior root ganglion cells and the anterior horn cells of the spinal cord degenerate, and when this has occurred sensory and motor symptoms will be permanent. Like Walshe (1945) I have never seen

\*Introductory Paper at a discussion at the Neurological Section of the International Congress of Medicine, Sept. 9, 1947.

a patient with chronic polyneuritis from any cause benefit from aneurin, but the therapy of chronic polyneuritis is no clue to its aetiology.

#### Wernicke's Encephalopathy.

The evidence that Wernicke's encephalopathy is due purely to aneurin deficiency seems conclusive. Epidemiologically it occurs at the same time as beriberi. According to de Wardener and Lennox (1947) neuritic, cardiac, and oedematous manifestations of beriberi were present in 79% of their patients at Changi. The pathological changes in the nervous system have been produced experimentally by aneurin deficiency (Alexander *et al.*, 1938, 1941; Prados and Swank, 1942). The level of pyruvate in the blood is raised and its return to normal in response to treatment is parallel with the clinical improvement (Wortis, Bueding, Stein, and Jolliffe, 1942). Finally, aneurin is completely effective in early cases (de Wardener and Lennox, 1947).

This raises the question why some members of a population exposed to aneurin deficiency develop encephalopathy or cerebral beriberi while others show the other manifestations alone, and why Wernicke's encephalopathy ceases to occur in an exposed population though neuritic beriberi continues (Fig. 2). Does this depend upon indi-

FIG. 2.—Hospital admissions of non-cerebral beriberi and Wernicke's encephalopathy, in ten-day periods, compared with aneurin/non-fat-calorie ratio of diet (mg. of aneurin per 1,000 non-fat-calories) (de Wardener and Lennox, 1947).

individual susceptibility or upon other factors, such as rate of onset, influenced, for example, by dysentery and diarrhoea, which de Wardener and Lennox found an important predisposing cause?

Though neurologists are concerned primarily with the neurological manifestations of aneurin deficiency it is well to emphasize that these are merely one by-product of disordered metabolism, which also profoundly affects the heart and blood vessels.

#### Pellagra

It is an old observation that pellagra is prone to occur in maize-eaters, and before the discovery of the B group of vitamins the cause of pellagra was thought to be an unknown toxic substance in the maize. It was then discovered that black-tongue, a disorder in dogs analogous to pellagra, could be caused by giving a diet deficient in nico-

tinic acid, and cured by giving nicotinic acid to affect animals. It seemed reasonable, therefore, to ascribe pellagra to deficiency of nicotinic acid. Later work, however, shows that this view was too simple. Krehl and his fellow workers (1945a, 1945b, 1946) have found that tryptophan relieves black-tongue produced by maize. It would seem that nicotinic acid and tryptophan or foods rich in tryptophan are to some extent interchangeable as preventives of black-tongue. It is suggested that tryptophan may lead to a change in the intestinal flora in favour of the synthesis of nicotinic acid in the alimentary canal. There is a further complication in that pyridoxin deficiency disorders the metabolism of tryptophan (Axelrod, Morgan, and Lepkovsky, 1945).

A different approach to the problem has been made by Kodicek, Carpenter, and Harris (1946), who have shown that maize has a high content of a plant hormone—indole-3-acetic acid, or hetero-auxine—which inhibits growth in rats and is again counteracted by nicotinic acid and tryptophan. This may be an important observation, since auxines are present in many foodstuffs—e.g., peas, beans, and lentils, especially when sprouting—and in cultures of yeast, moulds, and bacteria (Jensen, Avery, and Burkholder, 1936). Hence the consumption of peas, beans, and lentils with the object of increasing vitamin intake may in some respects have the opposite result, and foods contaminated with moulds may similarly counteract vitamins in the food.

All the evidence supports the view that pellagra is due to deficiency of nicotinic acid in the nervous system, but when we ask why the nervous system goes short we discover how many factors are involved. Not only must the diet contain enough nicotinic acid for the needs of the body, but it must be balanced in other respects. Too much maize counteracts the nicotinic acid either because maize is relatively deficient in tryptophan or because it contains an anti-enzyme to nicotinic acid. Maize must be balanced by nicotinic acid or tryptophan or foods rich in tryptophan. Secondary pellagra introduces additional factors, such as chronic alcoholism and diseases of the alimentary canal, which impair the synthesis of nicotinic acid in the intestine, its absorption and its storage, or operate in other ways as yet unknown.

There is still much to be learned about antivitamin B. In addition to hetero-auxine, which is an antivitamin B, there exists an antivitamin B to aneurin which causes Chastek paralysis, a disorder pathologically identical with Wernicke's encephalopathy, in foxes fed on raw maize (Green, Carlson, and Evans, 1942).

#### War Neuropathies and their Problems

It is doubtful whether the deprivations incidental to war brought to light any new deficiency syndrome, though some occurred on an unprecedentedly large scale. On the whole, disappointingly little new knowledge has been gained from this rich material, mainly because the complexity of the factors involved, together with the difficulties of the circumstances, made a clear-cut scientific approach impossible. Something has already been said about beriberi and Wernicke's encephalopathy. The other principal syndromes encountered were: (1) painful feet; (2) spinal ataxia; (3) spastic paraplegia; (4) certain cranial nerve lesions, especially retrobulbar neuritis, nerve deafness, and laryngeal palsies, which usually accompanied spinal ataxia; and lastly (5) a rare but interesting myasthenic syndrome. I shall not deal with these syndromes in detail, but will merely make some observations upon their aetiology.

(1) *Painful Feet*.—This common and comparatively simple syndrome well illustrates the difficulty of establishing the aetiology of deficiency disorders in man. The pathogenesis might have been inferred from (a) the association of the

syndrome with specific dietary deficiency, (b) the coincidence of its onset with that of other recognized deficiency syndromes in other persons, (c) its association with other syndromes in the same patient, (d) the effect of therapy. None of these has proved conclusive.

FIG. 3.—Peak periods of hospital admissions for principal deficiency diseases (de Wardener and Lennox, 1947).

(a) Dietary deficiencies were multiple, and it is difficult to select one as solely responsible, though Denny-Brown (1947) blames an exclusively cereal diet. (b) Chronologically the painful-feet syndrome occurred after the aneurin deficiency syndromes and somewhat after the onset of symptoms of hyperriboflavinosis, coinciding roughly with the peak of pellagra, spastic paraplegia, granular cornea, and the onset of retrolubar neuritis (de Wardener and Lennox, 1947) (Figs. 3 and 4). (c) Oral and scrotal symptoms of hyperriboflavinosis preceded the outbreak (Simpson, 1946) or were associated with it in about 30% of cases (Cruikshank, 1946); retrolubar neuritis was present in 10% (Simpson, 1946) and 13% (Cruikshank). Oedema and polyneuritis were rare according to Cruikshank, who found no associated disease in 42%. Raised blood pressure was found in 19% by Harrison and 30% by Cruikshank. (d) As to therapy, aneurin was ineffective; nicotinic acid or nikethamide gave the best results; foods rich in the B complex were less useful (Cruikshank). Intravenous calcium gluconate gave symptomatic relief (Harrison, 1946).

The same problems arise in connexion with the "captive cord syndromes": (2) *spinal ataxia* and (3) *spastic paraplegia*. These syndromes occurred later in time than beriberi and Wernicke's encephalopathy. Burgess (1946) groups them together with retrolubar neuritis and nerve-deafness as symptoms of hyperriboflavinosis, with the muco-cutaneous lesions of which they are associated. Denny-Brown considers that they are parts of the syndrome of pellagra, and Spillane (1947) draws attention to the resemblance between the spastic syndrome and lathyrism. Both spinal cord syndromes responded poorly to all known forms of vitamin therapy.

(4) *Cranial Nerve Palsies*.—The frequent association of two or more of these symptoms—anosmia, retrolubar neuritis, trigeminal anaesthesia, nerve-deafness, and laryngeal palsy—with or without spinal ataxia in the same patient, suggests a common cause, though the

evidence as to its nature is conflicting and inconclusive. Stannus (1944) suggests ariboflavinosis, and symptoms of riboflavin deficiency were present in Moore's (1937) patients, but these are by no means constant. Retrolubar neuritis may occur in association with beriberi, and so may laryngeal palsy, especially in infantile beriberi, but not deafness or spinal cord symptoms, and aneurin was of no value in treatment. Denny-Brown (1947) favours the view that this group of symptoms is pellagroid, but nicotinic acid proved of no benefit in treatment. Spillane and Scott (1945) incriminate lack of an undetermined element in the B complex. The cause is thus uncertain at present. As long ago as 1888, and again in 1897, Strachan (1897) described an epidemic in the West Indies of painful hands and feet, ataxia, retrolubar neuritis, deafness, and weakness of the voice, these nervous signs being associated with corneal damage and muco-cutaneous lesions of the eyelids, lips, tongue and nostrils. This fifty-year-old observation provides suggestive evidence for a common origin for this group of symptoms—and shows how little we have learned since.

### A Myasthenic Syndrome

A number of instances of a myasthenic syndrome, perhaps identical with Gerlier's disease, or kubisagari, have been observed among prisoners of war and attributed to dietary deficiency. I mention this because I have seen one patient in the convalescent phase. This man was never a prisoner,

FIG. 4.—Weekly incidence of various deficiency conditions compared with nicotinic acid and riboflavin contents of diet at Changi Camp (Burgess, 1946).

but fell ill while in the Army in Malaya after the war. He was not short of food, though most of it was tinned, consisting of soya sausage, bacon, beans, cheese, and fish, such as salmon. Bread was made by the field bakery. The only fresh vegetables were a small quantity of sweet potatoes and yam beans. He ate no tapioca or other cereals. His symptoms followed an acute febrile illness, and consisted of typical myasthenia involving cranial nerves and limbs, temporarily relieved by "prostigmin." He was unable to

walk for several weeks and then slowly improved. I am not convinced that this is a deficiency syndrome. A precedent febrile illness regarded as dengue occurred in Musselman's (1945) and Katz's (1946) patients, and Katz noted that the myasthenic symptoms were in inverse relationship to the severity of the fever. In my patient an infective toxin temporarily damaging the myoneural junction seems the probable cause.

### Intoxication or Deficiency?

Examples already given show that it is often difficult to distinguish between an intoxication and a deficiency. The verbal distinction is, of course, clear enough: a toxin is a harmful extra, a deficiency a harmful lack. But as soon as we get beyond the mouth difficulties arise. Food may be contaminated with a toxin, as, for example, Abyssinian wheat with flax-darnel (Brinton, 1945-6), or the food may be modified so as to become toxic, as the protein of agenzized flour causes canine hysteria (Mellanby, 1947; Moran, 1947). Or a normal constituent of food may be toxic only in the presence of vitamin or other deficiency—e.g., maize in pellagra.

Lathyrism gives rise to a spastic paraplegia which closely resembles the spastic syndrome occasionally seen in prisoners of war. Denny-Brown believes that lathyrism has not been proved experimentally to be due to *Lathyrus sativus per se*, and suggests that flour made from this pea may be deficient in tryptophan and that this may neutralize the action of a vitamin, the consumption of lathyrus thus bearing the same causal relation to lathyrism that the consumption of maize or cassava does to pellagra.

But maize is toxic only in the sense that it leads to a tissue deficiency of nicotinic acid, and it might be thought that the crucial question is the state of the nervous system. Even here, however, the distinction between intoxication and deficiency is not clear-cut. Peters *et al.* (1945) have shown that arsenite damages the pyruvate enzyme system in the nervous system, and from this sprang the discovery of dimercaptopropanol (British anti-lewisite, BAL), which was designed to resemble the tissue thiols, to combine in their stead with trivalent arsenic and so protect them. As we have seen, aneurin deficiency also damages the pyruvate enzyme systems, and both arsenical poisoning and beriberi are accompanied by a rise in the level of blood pyruvate. Thus it would seem that arsenical poisoning may act by causing a local enzyme deficiency, and aneurin deficiency by causing a local intoxication.

In the past we have tended to think that by describing a disorder as toxic we have explained it, but it was only our ignorance of the finer processes of the metabolism of the neurone that forced us to be content with such vague conceptions as "intoxication" and "toxic polyneuritis." All that we have learned about malnutrition should teach us that whatever happens to the nervous system—not only states of avitaminosis but head injuries, infections, vascular lesions, and demyelating disorders—will need increasingly to be considered not only from the standpoint of morbid anatomy but also in terms of the chemistry of the nerve cell.

(Figs 1 and 4 are reproduced from Dr. R. C. Burgess's paper on "Deficiency Diseases in Prisoners of War at Changi" (*Lancet*, Sept. 21, 1946, p. 411), and Figs. 2 and 3 from the article on "Cerebral Beriberi" by Captain H. E. de Wardener and Dr. B. Lennox (*Lancet*, Jan. 4, 1947, p. 11).)

## BIOCHEMICAL APPLICATIONS OF STABLE AND RADIOACTIVE ISOTOPES

BY

A. S. McFARLANE, M.A., M.B., Ch.B., B.Sc.  
National Institute for Medical Research, Hampstead

With but one exception the body does not discriminate between natural elements and their stable or radioactive isotopes. In addition the stable isotopes, with the exception of deuterium, have no deleterious effects on living cells even in the highest concentrations. In the case of the radioactive ones it is possible to employ such low concentrations that most human experiments can be carried out with safety, and all animal experiments with impunity, since genetic effects of the radiations can be ignored. These simple considerations have made possible to the biochemist a new kind of experimental approach which he has not been slow to use.

### Radioactive Phosphorus

One of the earliest isotopes to become available was radioactive phosphorus ( $P^{32}$ ), and of course it was administered as sodium phosphate by various routes to animals and its excretion observed and an analysis made of the skeleton and various organs to determine where and how long it was retained. It was soon established that only a small fraction—less than 10%—is excreted twenty-four hours, and of the total amount injected only a small proportion is present in the lymph and plasma a few

\*An address delivered to a joint meeting of the Physiology and Chemistry Sections of the British Association at Dundee on Sept. 1947.

ours after injection. The remainder has disappeared into the cells of the body, especially of the skeleton, the liver, and the intestine.

Precisely how this phosphorus is taken up by the cells is a matter of some general importance. By whatever route is injected a high concentration of  $P^{32}$  occurs within a few minutes in the lymph and plasma. From the lymph the cells take up phosphate at a steady rate and discharge it back at the same rate into the same medium. There is no discrimination between ingoing and outgoing phosphate, and complete mixing takes place within the cell. The process consists, in fact, of a continuous diffusion in both directions across the cell wall, radioactive phosphate passing out of the cell long before all the inactive phosphate in it has been replaced. If the concentration of radioactive phosphate in the lymph is kept constant—and there are several experimental tricks for doing this—the conditions are simplified and it can be shown that the radioactivity per gramme of phosphate in the cell rises exponentially with time. Since the exponential curve is almost linear in the first part of its course, a simple measurement of the specific activity of cellular phosphate, after a time interval which is short in relation to the time required to replace all the phosphate, is sufficient to determine the steady rate of exchange of phosphate in the cell. For example, after four hours the activity of the phosphorus in the tibia of a rat is one six-hundredth that of the phosphate maintained constant in the lymph, and we may conclude that in four weeks an amount of phosphorus passes into and out of this bone equal to the total weight of phosphorus in it. This is called the replacement or turnover time. In a few cases where the turnover time is short it is possible to make allowances for the non-linearity of the growth curve and to obtain exact turnover values; but in general this is not possible, and the results obtained by assuming linearity are known to be of the right order only. However, to know the larger turnover times accurately and the shorter ones approximately has proved to be a matter of great importance to our understanding of the chemistry of the body.

### Phosphorus Compounds

The phosphorus taken up by the skeleton is laid down for the most part in inorganic form, but elsewhere in the body it is incorporated into a large and still expanding group of complicated organic compounds. Outstanding among these are the phospholipids which are present in the blood plasma and in all cells. By transfusing radioactive plasma phospholipids to a dog and observing their rate of disappearance from the recipient's plasma, Chaikoff and his collaborators (Fishler *et al.*, 1943) have shown that the plasma phospholipids are replaced in six to ten hours. The liver is the main site of synthesis and degradation of these substances, since removal of the liver prolongs the turnover time to 33–160 hours. Removal of the intestine, on the other hand, has no effect. Although the liver produces enough phospholipids to renew the plasma reservoir inside ten hours it requires fifty hours to renew its own phospholipids. The intestine renews its phospholipids in forty hours, but the brain, which is rich in these substances, requires four weeks for their replacement.

Another important phosphorus compound of the body is nucleic acid, of which two main types are present—one characteristic of the nuclei, and the other found in high proportion in the cytoplasm of all cells. The P in the nuclear form is exchanged very slowly—about the same as in bone—but in the cytoplasmic form it is exchanged ten times as quickly. That is the position in normal adult cells, but when the cells are dividing—e.g., in embryonic tissues,

in regenerating tissues, or in malignant growths—the position is vastly changed, the nuclear P exchange increasing ten to fifteen times. This confirms and establishes on a quantitative basis general impressions derived from the histology of the tissues; but the tracer method can go further than this—it can distinguish the rate at which nucleic acid  $P^{32}$  builds up inside a cell from that at which it disappears. In this way—and in no other—it can be shown that growth from any of the causes mentioned results not from an increased rate of synthesis of cell compounds but from a diminished rate of disintegration, so that the organism reaches maturity when it has accelerated its intracellular breakdown processes until they are as rapid as the synthetic ones.

It is clear also in all these studies that some injected phosphorus is excreted into the lower bowel, and it can be demonstrated that part of the phosphorus of our diet which is absorbed in the upper alimentary canal is re-excreted and mixed with unabsorbed phosphorus in the lower. An entirely different picture comes to light if this experiment is repeated using radioactive iron in the diet. Hahn *et al.* (1939) have shown that in a normal adult practically all the iron passes through the gut unabsorbed, but if the subject has been made anaemic new radio-iron is absorbed into the circulation. The new red cells which are produced differ from the old ones in having some of this radio-iron incorporated in the haemoglobin molecule. These radioactive cells persist in the circulation for some months, as do all red cells, and are finally destroyed in the spleen and liver, where their iron is stored. In time this iron finds its way back into the circulation for incorporation into new red cells. Here once again the tracer element is able to reveal something which could not have been discovered in any other way—namely, that the body is extremely conservative in relation to this particular constituent of the diet, endeavouring so far as possible to carry with it enough iron circulating internally to meet all its requirements. It is as conservative in relation to iron as it is liberal in relation to phosphorus. The mechanism by which the intestinal mucosa “senses” internal iron deficiency and responds by allowing some of the element to pass from the gut into the blood is not yet understood, but its beauty is impressive.

### Glycine

A few days after administering the amino-acid glycine containing  $C^{13}$  in the methyl group and  $N^{15}$  in the amino-group to rats the isotopes are found in adjacent positions in the protoporphyrin of haemoglobin. This tells us much about the manner in which the body synthesizes the five-membered pyrrole ring and at the same time provides a convenient method of labelling the red cells of the blood. If N-labelled glycine is given to a human being the isotope is detectable in the red cells at the fourth day and the concentration rises steadily over a period of twenty-five days, remaining constant for a further fifty days, and dropping slowly to zero in the next 150 days.

Shemin and Rittenberg (1946), who first observed this behaviour, were quick to note its unusual character. Normally when a tracer is injected the concentration of labelled compound in a tissue or organ rises to a maximum as synthesis proceeds and immediately thereafter declines again as the labelled molecules are metabolized. The fifty-day period of constant isotopic porphyrin concentration can be explained only in one way. The porphyrin of the newly formed red cell is excluded from the metabolic reactions of the body and enters into these again only at the end of the life-span of the red cell. Statistical analysis of the results shows that the average life of a human red cell is 127 days. This method is not the only one leading to this result, but

it is particularly elegant in involving no more disturbance to the subject than is associated with feeding labelled glycine. The method further reveals that, when the red cell finally disintegrates, the porphyrin group, unlike iron, is not further utilized in the formation of new red cells but is excreted in the bile.

The body contains three important substances—choline, creatine, and methionine—with no obvious chemical relationship to each other except that each has a methyl group linked to the rest of the molecule through sulphur or nitrogen. Deficiency symptoms due to the absence of choline from the diet can be cured by giving methionine, and the absence of both choline and methionine from the diet affects the excretion of creatine as creatinine. There is clearly, therefore, a metabolic interdependence between these three substances, and a clue to its character is found by administering one of them with deuterium in the methyl group. The isotope is subsequently found in the methyl groups of the other two and nowhere else. It seems, therefore, that a methyl group linked through sulphur or nitrogen is handled by the body quite differently from a methyl group linked through carbon. We are introduced here to the idea of a vitamin-like importance in the diet of a particular radical. In not dissimilar fashion the amino-groups of all the amino-acids of the diet are merged in a metabolic pool from which the amino-acids of the tissues are derived. This is shown by administering N-labelled glycine or ammonia and finding the isotope in all the amino-acids except lysine of the tissue proteins.

### Carbon

If carbon dioxide containing isotopic carbon is breathed in it is found that some of the carbon finds its way into glycogen in the liver and from there to other compounds of the body, thus disposing in one simple experiment of the belief that only plants and bacteria can utilize carbon in the form of carbon dioxide. Needless to say, biochemists in the last few years have investigated this phenomenon intensively, and no fewer than six distinctive chemical reactions are now known by which the body can fix carbon dioxide, the most important one being the condensation of carbon dioxide with pyruvic acid to give oxalo-acetic acid.

Arising out of this and other experiments much attention has been paid in recent years to acetic acid. In the past this has been little investigated because it is known to be present in insignificant quantities in the body and these are extremely difficult to measure precisely. With the advent of isotopes, however, an inefficient method of isolation may be made the basis of a precise method of estimation, as the following example will show. Supposing a compound containing  $C^{13}$  is given in the diet and we wish to know whether any part of this  $C^{13}$  is incorporated into acetate in the liver. A known weight of liver is mixed thoroughly with a known but excessive weight of normal acetate and the mixture is fractionated to recover a proportion of the acetate. At the same time a like proportion of labelled acetate is recovered—minute in amount but sufficient for mass spectrometric estimation. Multiplication of the result by the recovery factor tells us the weight of labelled acetate in the piece of liver. This has become an important general method of analysis known as the isotope dilution method.

When a fatty acid labelled in the carboxyl carbon is oxidized by the liver some acetate—but considerably more aceto-acetate—is found. This aceto-acetate is labelled in both carbonyl and carboxyl groups, indicating that it is formed by condensation of acetyl groups, methyl to

carboxyl. Aceto-acetate is not further utilized by the liver but is oxidized elsewhere. The kidney, among other organs, can oxidize it and is known also to take up acetate, but normally no aceto-acetate can be found there. By incubating kidney slices with labelled acetate in the presence of an excess of normal aceto-acetate and demonstrating the presence of isotopic aceto-acetate in the excess recovered Medes *et al.* (1945) have shown that the oxidation of acetate is in fact through aceto-acetate, but the latter is normally further oxidized as soon as it is formed.

An alternative tracer procedure to the above has been to feed labelled acetate and to investigate the more complicated molecules of the body to find what has happened to that part of it not immediately excreted. By this procedure the carbon skeleton of acetate has been identified in the dicarboxylic amino-acids of the tissue proteins, in the fatty acids of the liver and depot fats, in cholesterol, and in glycogen. It has been shown (Bloch and Rittenberg 1945) that although the carcass of a 100-gramme rat contains but a few milligrams of acetate, more than a gramme of acetate is produced in its liver every day.

### Conclusion

These developments, which are largely if not exclusively derived from isotopic studies, represent substantial contributions to biochemistry. They reveal numerous unsuspected metabolic pathways, and if some of these are but little used normally—as, for example, the fixation of  $CO_2$ —they may be of the greatest importance in disturbed metabolic states: e.g., in diabetes, where aceto-acetate and related ketone bodies are produced in abnormal amounts. They demonstrate that the quantity of substance in a tissue bears little if any relation to its metabolic importance, and that important intermediary metabolites may not even be present in detectable concentrations, thereby heralding a new dynamic point of view in which the body is conceived as in a state of incessant change, atoms and molecules displacing one another with surprising rapidity in every tissue. All that remains constant is the pattern into and out of which these atoms pass—a stereo-chemical relationship of atoms within molecules, and a spatial juxtaposition of molecules within tissues—which is specific for each individual and characteristic of living matter as a whole.

The Annual Report for the year ending July 31, 1947, has been issued by the Royal College of Surgeons of England. It draws attention to the Supplemental Charter which was granted on May 20 and states that new by-laws have been submitted to the Home Office for approval. Fellows and members of the College have been co-opted to the Council in order to include various branches of practice not represented by the ordinary process of election. Arrangements have been made to hold special final Fellowship examinations in ophthalmology and otolaryngology, and the court of examiners is being enlarged to include the necessary specialists. Regulation for the Fellowship in dental surgery have been approved and the first 18 Fellows elected. The building of a residential hostel for post-graduate students is planned. During the year 158 Fellows have been admitted. After Jan. 1, 1949, candidates will not be admitted to the final Fellowship examination until three years after qualification and until they have served a period of twelve months in posts approved by the Council, six months of which must have been occupied in residence in a hospital recognized for the purpose.

## DIABETES INSIPIDUS AND UTERINE ATONY

A CASE OBSERVED OVER A PERIOD OF 26 YEARS

BY

G. MARAÑÓN

Professor of Clinical Pathology, Madrid University

Only the briefest references are found to the development and social behaviour of patients with diabetes insipidus. It may not be without interest, therefore, to give a detailed clinical history of a woman suffering from this disease whom I have observed for 26 years.

### Case History

In December, 1921, a 17-year-old girl was sent to me for the first time by her doctor. There was nothing of interest in her family history. She had suffered from an occasional sore throat and migraine. Her appearance was normal except for slight oedema of the eyelids, dry skin, and slow reactions, which might have suggested some slight thyroid insufficiency. Menstruation had first appeared at the age of 15, and was irregular, with periods of amenorrhoea lasting a month or two.

Four months before coming to see me she had had a sudden immersion at the seaside, which had greatly upset her: the weather was cool and she had the sensation of having got very cold. From that day she had begun to pass water frequently and had grown considerably more thirsty, but had had no other abnormal symptoms. Of course, diabetes insipidus was diagnosed, based on the extraordinary thirst and polyuria and on the first tests made by the family doctor.

Clinical examination revealed nothing abnormal apart from the menstrual disorders. The sella turcica was normal. Examination of the eyes, carried out by Dr. Celada, revealed: "Reduction in the visual fields in the nasal and temporal halves, particularly the latter. The reduction in the superior and inferior part is equal to that of the nasal half: in the right eye, above, below, and internally, it amounts to 40 degrees; externally, to only 30 degrees; in the left eye, 30 degrees above, below, and internally, and 20 degrees externally. Disks slightly reddened, but no swelling. Visual acuity normal. No abnormality of the extrinsic or intrinsic muscles." Examination of the urine showed: 24-hour volume, 9.5 litres; specific gravity, 1.002; reaction, alkaline; chlorides, 0.6%; urea, 2.6%; uric acid less than 0.25%; no glucose or albumin; deposit, nil.

An injection of 1.5 ml. of "pituiratin" caused pallor and a sensation of coldness, together with a reduction in the polyuria and thirst which lasted for three hours. Analysis of the urine during the next 24 hours showed: volume, 8.75 litres; S.G., 1.003; reaction, alkaline; chlorides, 1.6%; urea, 1.96%; uric acid, less than 0.25%. There was some doubt about the efficiency of the pituitrin used for this test. The Wassermann reaction was negative. A full diet was recommended, and periodical injections of pituitrin and daily injections of "ovarin" and belladonna were prescribed.

April, 1922.—The patient improved considerably as a result of the first pituitrin injections, and the thirst and polyuria diminished without further trouble, other than pallor and urgency of defaecation after the injections. The tenth injection, however, produced intense dizziness and faintness. These effects were repeated and she had to give up the injections. A month later the dizziness grew less, but there remained a state of slight spasticity in the left arm and leg with coldness of the extremities, which had to be wrapped up in warm clothing. The slightest excitement produced palpitation. The thirst and polyuria had returned to their original state. A mercurial salt was prescribed, but she soon gave this up as it upset her and did not relieve the polyuria.

May, 1927.—I had not seen the patient for the last five years, during which time she had followed no treatment. The thirst and polyuria continued the same, but she had become accustomed to them. She was now suffering from severe headaches, with bright spots before the left eye. The spasticity of the limbs had disappeared. She was passing 20 litres of urine in 24 hours. The blood pressure was 140/80 and blood

chlorides 555 mg. per 100 ml. There was a considerable increase in the size of the left breast, with great enlargement of the areola and nipple and exudation of drops of a serous liquid with some admixture of blood, which issued both spontaneously and on pressure. I prescribed a weekly injection of a new posterior-pituitary preparation, and, in addition, strychnine and insulin, and a chloride-free diet.

October, 1927.—She had not been able to stand the pituitary injections after the third and fourth, and therefore gave them up as well as the rest of the treatment. The polyuria and thirst persisted. The nervous phenomena had disappeared. The breast condition had not altered.

February, 1933.—The diabetes insipidus was still the same and she followed no treatment. She had married the year before. Pregnancy began at once and she was much troubled by vomiting. Later, parturition seemed to start several times, but the pains stopped almost immediately. After five days without further pains she was delivered of a full-term female child, which was stillborn. There was no change in the polyuria and thirst during pregnancy. She now consulted me because she had had "influenza" and was left with intense headache and uncontrollable projectile vomiting. Menstruation was normal, though scanty. No abnormality was found in the nervous system. Pituiratin and a sedative for the vomiting were prescribed.

February, 1935.—She told me that the cerebral phenomena had soon ceased. Her general condition was good. Since her confinement the polyuria had dropped to about 7 litres a day, with a parallel lessening of the thirst. She followed no treatment. Menstruation was still scanty but regular. In the interval since her previous visit she had become pregnant again, having had a spontaneous miscarriage at the third month. The blood pressure was 130/60. A fresh Wassermann reaction proved negative: when the blood was taken from her for this she had a severe faint. I suggested radiotherapy of the pituitary region, but she refused.

October, 1935.—She wrote that she was pregnant again, and she had the same polyuria and much sickness. I advised cortical extract in small doses, and the necessary quantity of pituitrin at the time of parturition.

March, 1936.—The pregnancy ended happily. Her labour pains were very slight, but, as I had advised, she was given at intervals up to five injections of pituitrin, thanks to which normal delivery of a full-term child was obtained.

May, 1936.—She wrote that she was again pregnant.

April, 1947.—I saw her again after this long interval (due to the Spanish war and its consequences). The 1936 pregnancy also ended with a total cessation of the labour pains almost as soon as they had started. Owing to the abnormal circumstances in which she found herself she was unable to obtain pituitrin, and three days after the cessation of the labour pains a dead foetus was removed. The patient is now 43 years old. She lives with her daughter—her only living child—who is completely normal. The mother also appears normal. She still has to drink a great deal—three litres more or less during the night alone—and micturition is proportionately abundant; but she feels well and has become accustomed to so much drinking and passing of water. She leads a normal life. Her periods are regular and the flow very scanty. A year ago the dizziness reappeared and she also has sensations of cold in the limbs on the left side. Analysis of urine showed: volume, 11 litres; S.G., 1.006; no abnormal constituents. Blood sodium, 284 mg. per 100 ml.; blood calcium, 4.08 mg. per 100 ml. The blood pressure was 170/90. There was slight accentuation of the aortic second sound. A radiograph of the cranium was normal except for slight frontal hyperostosis. A preparation of folliculin was prescribed with "euphyllin" and phenobarbitone occasionally.

### Comment on the Case

The diabetes insipidus in this case is of the kind called "essential," though mistakenly, since present-day anatomical and experimental data enable us to assert that there is always a disturbance of the hypothalamic-pituitary mechanism in these essential cases as well as in the "symptomatic" ones, the only difference being that in the

latter the neoplastic, syphilitic, traumatic, or other lesion can be diagnosed, whereas in the former it cannot. The distinction between essential and symptomatic diabetes insipidus still found in books as up to date as Duncan's (1946) and others must be abandoned.

A curious factor in the case is the aetiology and particularly the sudden immersion, which the patient points to as the starting-point of her polyuria. I believe I was the first (Marañón, 1920)—and I may have been the only one—to call attention to this type of aetiology by publishing illustrative cases. The important subject of emotion in the aetiology of endocrine disturbances has again become topical on account of the increased interest in psychosomatic medicine. There is no doubt that the endocrine glands, owing to their dependence on the vegetative hypothalamic centres, play a constant and essential part in the physical changes of emotion, and it may be supposed that if there is previously a state of unstable equilibrium in the function of one of these glands, due to congenital weakness or to a latent lesion, such emotional changes may be enough to upset the balance and give rise to the clinical syndrome. Immersion, which is generally accompanied by an impression of sudden terror, might by this mechanism—i.e., by acting on an unstable hypothalamic-pituitary system—cause the clinical appearance of diabetes insipidus. It is observed that a passing polyuria is a habitual consequence of immersion in cold water; therefore diabetes insipidus might be the pathological prolongation of a physiological occurrence.

In the long course of the patient's illness I have never been able to assert the existence of any pituitary, midbrain, or other localized lesion. Yet it must be remembered that on several occasions she has had severe attacks of headache, some with vomiting, scintillating scotoma, and spasticity and paraesthesiae localized to the limbs of the left side. These phenomena have usually appeared after the injection of pituitrin. In my experience intolerance of pituitrin is very common in cases of basal cerebral lesions. Remember, too, the spontaneous unilateral hypertrophy of one of the breasts, with a serous secretion, which phenomenon also occurs in cases of neoplastic lesions of the hypothalamic-pituitary mechanism. Therefore, we may be dealing with a non-malignant non-progressive lesion of small size: this would explain the absence of permanent focal symptoms. There was never any possibility of confirming this supposition by the normal methods of investigation.

### Discussion

Authors refer in vague terms to the "course" of diabetes insipidus. This varies very much from one case to another. In 1920 I wrote that in the course of diabetes insipidus "the usual thing is variety." In general it is accepted that the course depends on the lesion causing the condition, and cases can accordingly be classified under three headings: (a) *Cases with a rapid course*—those produced by malignant tumours of the pituitary or the hypothalamic region; (b) *Cases with a medium course*—those produced by lesions capable of cure spontaneously or by treatment, or which cause death after a period of chronicity, such as traumatic haemorrhages and syphilitic or tuberculous lesions; and (c) *Cases with a very prolonged course*—those in the *essential* group—i.e., without discoverable lesions; according to the various authors the average duration of these cases is from twenty to thirty years. One of Weil's patients had had the disease from childhood and lived to be 80. But I have not come across any case under one single observer with such a long history as the present one.

It should be noted that in my case, as in others among those published, the patient finally gave up treatment with

posterior-pituitary extract injections. This often occurs when there are symptoms of intolerance. But after some time the system becomes adapted to the pathological thirst and polyuria. These patients end by arranging their life to fit in with this need of water and their need to micturate doing so automatically and in a way compatible with normal existence. They even spend good nights, drink and passing water in a manner compatible with sleep. A patient was in despair at first because of her polyuria, now she is quite untroubled by it.

What I particularly want to emphasize is the *behaviour of the patient's reproductive function*. On this point authorities are extremely vague. Yet it is known that some women with diabetes insipidus have been able to have children, although it is true that they sometimes pass the disease on to their offspring with a dominant Mendelian character. A family described by Weil is always mentioned: in 11 generations there were 220 members and 35 cases of diabetes insipidus (see Marx, 1945). I have seen only one hereditary case (Marañón and Bonilla, 1925)—a mother with diabetes insipidus which appeared and disappeared spontaneously whose child had severe diabetes insipidus from the age of five months. The majority of diabetic women either do not marry or are sterile.

In the present case the syndrome of uterine atony is very curious, occurring as it did in all her confinements. The role of the oxytocic hormone, or oxytocin (produced in the posterior lobe of the pituitary), in the mechanism of normal parturition is not yet clearly understood, nor is it universally accepted. If this action is admitted—and I am one of those who do admit it—we have also to admit that deficiency of the hormone may produce a deficiency in the uterine contractions and, therefore, abnormal parturition. Physiologists are usually very reserved in this respect, basing their ideas on the fact that in animals extirpation of the posterior lobe does not prevent pregnancy or parturition (Houssay and others, 1946). But, as Houssay recognizes these experiments are worthless, since it is known that an extirpation of the posterior lobe there are left in the pituitary stalk and tuber the remains of posterior pituitary tissue capable of fulfilling the functions of the latter. On the other hand it has been proved that electrical stimulation of the pituitary body precipitates and intensifies uterine contractions in pregnant rabbits, just as would occur if oxytocic hormone were injected (Haterius and Ferguson, 1938). It has also been proved that experimental section of the supra-optic-hypophysial tract, which joins the hypothalamus to the posterior pituitary, in pregnant females results in a prolonged labour with incomplete expulsion or even non-expulsion of the foetus and sometimes a concomitant polyuria (Fisher, Ingram, and Ranson, 1939).

Physiologists have failed to note some facts in clinical knowledge which confirm these experimental findings. I refer to the observations published by Cushing (1932) by myself and Richet (1940) of repeated uterine atony due to lesions of the posterior lobe of the pituitary. As I have repeatedly commented on such cases elsewhere, I cannot myself here to recalling them. Cushing's case was that of a woman with intractable uterine atony who later showed signs of a basal tumour; at operation a tumour destroying the posterior lobe was found. My case was that of a woman in whom, following an attack of epidemic encephalitis, there appeared a severe syndrome of posterior pituitary insufficiency with repeated and intractable uterine atony. It is true that such cases of uterine atony due to posterior-pituitary lesions are very rare, but this can be explained by the fact that women with such lesions seldom become pregnant. But the published cases are suggestive, and the present case furnishes further evidence.

## Summary

Personal observation of a woman suffering from diabetes insipidus over a period of 26 years has enabled me to ascertain the complete adaptation of such a patient to a normal life when the lesion is not fatal. It has also enabled me to study one more case of uterine atony undoubtedly related to hypothalamic-posterior-pituitary insufficiency.

## NEPHRITIS IN TEXTILE WORKERS

BY

ROBERT PLATT, M.D., F.R.C.P.

Professor of Medicine, University of Manchester

On May 24, 1947, in a leading article in the *British Medical Journal* (p. 727) on the subject of oxygen poisoning, the statement is made that "the inhalation of textile dusts is a steady source of death from nephritis and a group of conditions whose common factor is hyperpiesia."

It is the purpose of this paper to examine the evidence on which this statement is based. The information is obtained from the Registrar-General's Decennial Supplement for 1931, which shows a considerably increased mortality due to nephritis in certain groups of textile workers. In this fascinating document the causes of death are compiled from death certificates in the years 1930-2. I do not happen to have a textbook of medicine of that date readily available, but the fifth edition of Price's *Medicine*, published in 1937, still describes chronic interstitial nephritis as an entity and does not mention malignant hypertension at all. We must therefore from the outset be on guard against the assumption that nephritis appearing on a death certificate in 1931 bears any relationship to nephritis as commonly understood among physicians in 1947. Fortunately we can investigate this initial difficulty fairly easily.

The age incidence of deaths from nephritis and similar causes in 161 cases of which I have personal records is shown in Table I. From this it is quite clear that the main

TABLE I.—Deaths from Renal Disease: Author's Cases

Age (years):	0-14	15-24	25-34	35-44	45-54	55-64	65-69	70+
Nephritis, type I (Ellis)	7	17	15	6	5	0	0	0

Polycystic kidney ..	0	0	1	0	1	0	0	0
Chronic pyelonephritis ..	0	3	4	10	1	1	1	1
Amyloid kidney ..	0	0	0	4	0	0	0	0
Pregnancy kidney ..	0	1	1	2	1	0	0	0
Diabetic kidney ..	0	0	1	1	3	5	0	0
Miscellaneous renal deaths (nephritis nodosa, renal Tb., hydronephrosis, etc.)	0	5	2	4	4	6	2	0
Total renal diseases ..	16	45	31	32	18	15	3	1
Malignant hypertension ..	0	0	0	12	25	8	0	0

The above figures do not include non-renal deaths from essential hypertension or deaths from prostatic obstruction.

incidence of death from nephritis is under the age of 45. Only when deaths from malignant hypertension are added does mortality become considerable at 45 to 55 years of age.

The Registrar-General's figures for the age incidence of death from nephritis are totally different, as shown in Table II, where it will be seen that the main mortality is

TABLE II.—Deaths from Nephritis (Registrar-General, 1930-2; Death Rate per 100,000)

Age (years):	16-24	25-34	35-44	45-54	55-64	65-69	70+
Males ..	15	9	18	49	108	219	389

Single women ..	15	9	17	36	74	128	247
Total ..	41	27	53	125	268	507	875

over the age of 45 and must largely consist of deaths from hypertension. It is my experience in consulting practice that many cases of hypertensive heart failure with albuminuria are diagnosed by their doctors as chronic interstitial nephritis. There is a slight difference in age distribution between the various social classes, in that the lowest class has a rather higher percentage of deaths in younger persons; these are probably deaths from true nephritis related to infections.

The mortality from so-called nephritis for the combined social classes III and IV (into which the textile workers fall) is shown in Table III, and in Table IV are listed the deaths from nephritis in those groups of textile workers in which the mortality from this complaint is said to be excessive.\* It will be seen that the increased mortality

TABLE III.—Deaths from Nephritis in Social Classes III and IV combined (Registrar-General, 1931)

Age (years):	16-	20-	25-	35-	45-	55-	65-	75+

Percentage ..	1.2	2.0	4.3	6.4	14.5	23.4	30.4	18.0

TABLE IV.—Textile Workers with Excessive Incidence of Deaths from Nephritis (Registrar-General, 1931)

Age (years):	16-	20-	25-	35-	45-	55-	65-	75+
Group 29 (textile spinners—cotton)	3	2	3	5	17	19	39	15
.. 30 (textile spinners—wool worsted, etc.)	0	1	2	2	3	3	4	3
.. 32 (textile weavers—wool worsted, etc.)	0	0	2	1	11	6	11	7
.. 33 (textile strippers and grinders—cotton)	0	0	1	0	5	5	0	0
.. 34 (textile dyers)	0	2	2	2	11	19	19	6
Totals ..	3	5	10	10	47	52	73	31
Percentage ..	1.3	2.2	4.3	4.3	20.3	22.5	31.6	13.4

occurs between 45 and 55, the age of essential hypertension, not that of nephritis.

If it is in fact hypertension which causes excessive mortality from "nephritis" in cotton workers one would expect an increased incidence of other effects of hypertensive disease. The standardized mortality ratio (S.M.R.) of cerebral vascular lesions, compared with that of nephritis for the occupational groups concerned, is therefore shown in Table V, and it is clear that mortality from cerebrovascular disease is about as much in excess of normal as that from so-called nephritis.

At this stage the impatient reader might remark that whatever name is given to the disease there is an increased

\* Analysis of Tables III and IV by the  $\chi^2$  test shows  $P > 0.9$ . The differences in age incidence of nephritis in textile workers and in the population from which they come is therefore not significant.

TABLE V.—Standardized Mortality Ratio at Ages 20-65  
(normal 100)

Group		From Nephritis	From Cerebral Vascular Lesions
29	Cotton spinners .. ..	135	151
	Wives .. ..	136	131
33	Cotton strippers and grinders ..	220	217
	Wives .. ..	233	175
34	Textile dyers .. ..	171	170
	Wives .. ..	93	144
174	Cotton blow-room workers ..	300	200
	Wives .. ..	200	33

The figures in italics are not statistically significant owing to the small numbers of certified deaths concerned.

mortality among certain trades from some condition certified by doctors in 1930-2 as nephritis, and it is not a matter of first importance what nomenclature is used to describe it. But there is a fundamental difference in aetiology between nephritis and essential hypertension in that the one is, so far as we know, largely the result of environmental factors (reaction to infection), whereas in the other the main and overriding factor in aetiology is heredity (Weitz, 1923; Hines, 1937-8; Platt, 1947). In other words, one would look first for environmental factors such as humidity, conditions of work, nutrition, and liability to infection if true nephritis were proved to be common in a certain group of work-people, but one would look first for evidence of inbreeding if one were investigating essential hypertension. This does not mean that the liability to death from essential hypertension cannot be influenced by environment; it is merely a matter of the most likely major influence at work, for in general it will save time and mistakes to examine that first. It will be seen from Table IV that the wool workers (groups 30 and 32) together contribute less than a quarter of the deaths from nephritis to the total for the three years in question, and we will therefore confine our remarks to the cotton industry.

Inbreeding, of course, is well known to occur in cotton towns, and to a large extent we are dealing with hereditary trades. If hereditary influences are at work in a disease like hypertension with a roughly even sex distribution we should expect the wives of workers in the affected groups to be affected. That this is the case is also shown in Table V, and it is interesting to contrast these figures with those for paperhangers and painters, in which the possibility of lead poisoning arises. In these trades the high S.M.R. for nephritis (131) and cerebrovascular lesions (151) in the men is not shown among their wives, for whom the figures are 86 and 82 respectively. Before accepting this very striking demonstration as proof against an industrial cause of nephritis in the textile trades, however, it must be admitted (as indeed it is noted by the Registrar-General) that many of the married women are also engaged in the cotton trade and so may be exposed to the same influences as their husbands.

If heredity is at work one might expect some increase of hypertensive disease in the surrounding population. This is in fact the case, for the S.M.R. in the region North IV (Lancashire and Cheshire) in 1931 was 122 for nephritis and 119 for cerebrovascular lesions (normal 100). These are considerable increases, having regard to the size and heterogeneity of the population.

The percentage of persons suffering from any hereditary disease in a population will tend to remain stationary under conditions of random mating, so that communities relatively isolated and inbred may for a long while show a tendency to suffer more from a particular inherited trait than the population at large.

A difficulty arises over occupational group 31 (textile weavers—cotton), in which the mortality from nephritis

is not excessive (S.M.R., 84). There are two reasons for not accepting this discrepancy as weighing heavily in favour of an occupational factor, however. The first is that the figure of 84 is not statistically significant, the numbers of deaths being too small; and the second is that the mortality from nephritis in the 1921-3 report was actually a high one—i.e., the cotton weavers in previous years suffered the same mortality from so-called nephritis as their workmates in other branches of the trade. The mortality for wives in this group is unfortunately not stated.

In Table VI an estimate of deaths from degenerative cardiovascular diseases in various occupational groups has been made by combining deaths (at ages 35 to 70) shown as cerebrovascular lesions, myocarditis, angina pectoris and nephritis. It is seen that group 70 (clergy) actually have the highest incidence because of a likelihood of dying from angina pectoris. The second column of figures shows the deaths from cardiovascular degenerative diseases, omitting angina. This table merely illustrates how occupational groups differ with regard to degenerative diseases in general. If these figures do not prove that angina among clergymen is due to the inhalation of incense they also fail to prove that nephritis in cotton workers is due to the inhalation of textile dusts.

TABLE VI.—Percentages of Occupational Groups dying of Degenerative Cardiovascular Disease at Ages 35 to 70

	Deaths	The Same Without Angina
Group 31: Textile weavers—cotton (no abnormal mortality from nephritis; S.M.R., 94)	29.1%	27.4%
.. 34: Textile dyers (nephritis S.M.R., 171; total S.M.R., 123)	30.9%	28.7%
.. 35: Makers of textile goods, etc. (mortality generally normal; S.M.R., 93)	26.6%	22.6%
.. 70: Anglican clergy (S.M.R., 69)	35.4%	25.3%
.. 81: Draughtsmen, costing clerks, etc. (very healthy; S.M.R., 65)	23.5%	19.7%

Knowledge advances and fashions in certification change. The accuracy of all statistics is dependent upon the accuracy of the data from which they are compiled. Owing to the war the next decennial report will presumably be based on the 1951 census (1941 being omitted). I venture to predict that by that time there will be a sharp decline in nephritis among older persons and a corresponding increase in deaths from hypertension and hypertensive heart failure.

In certain textile trades there may be influences at work whose effect is to hasten or even to initiate cardiovascular and "renal" disease. This investigation of the evidence does not disprove such a possibility, but it suggests that before setting out on a laborious, time-consuming, and expensive investigation into the cause and prevention of nephritis in textile workers we should need more evidence that it exists. In particular we would require evidence that there is a renal syndrome among textile workers which is in some way different in its incidence, symptomatology, or course from hypertensive disease in the general population.

### Conclusions

This paper proves nothing. It suggests that the deaths from so-called nephritis in textile workers are in all probability due to hypertension, and can be as easily explained by natural variations in the genetic constitution of an inbred population as they can by environmental influences.

This should be borne in mind before making the assumption that such deaths are due to "the inhalation of textile dusts."

## Medical Memoranda

### Volvulus in a 48-hour-old Baby: Operation: Recovery

The "acute abdomen" in a baby 48 hours old is very rare indeed. Volvulus due to some developmental defect is perhaps the commonest cause in the newborn. The general symptoms of intestinal obstruction given by Zachary Cope (1946)—shock, vomiting, constipation, distension, and visible peristalsis—were all present in the following case, but were difficult to interpret.

#### CASE REPORT

The patient was a male first child of a mother aged 29 and a father aged 32. The mother showed a renal glycosuria from the fifth month of pregnancy and a mild thyroid deficiency. The presentation was occipito-posterior, and rotation was spontaneous. The child was born at 12 noon on June 18, 1947, after twelve hours' labour, delivery being normal. Vernix caseosa was rather more than usual. The child weighed 8 lb. (3.6 kg.).

About four hours after birth the child began to vomit yellow fluid, followed later by bile-stained fluid. He vomited and cried intermittently through the whole of the following night, and next morning was put on glucose-saline, which he returned immediately. He refused the breast and cried after the glucose-saline feeds. No meconium had been passed since birth. Abdominal distension was not detected, but I made a provisional diagnosis of stenosis of the duodenum. The father informed me that he had noticed a small amount of bright red blood in the vomit.

On the morning of the 20th the child looked thin, dehydrated, grey, and shocked, and on being put to the mother's breast he vomited a large amount of altered blood-stained fluid. Dr. Morton-Stewart was called in consultation, and the case was considered to be haemorrhagic disease of the newborn. The child was given 10 ml. of the father's blood intramuscularly and an injection of "kapilon." I saw the child again six hours later, when a glycerin enema was given without result. Faecal vomiting very similar to that of an adult began and the abdomen was noticed to be distended. Visible peristalsis was observed. Dr. Morton-Stewart was again seen in consultation, when the diagnosis of intestinal obstruction was made. Mr. Young was also called in consultation. A catheter was passed down the oesophagus to investigate whether the abdominal distension was from stomach or bowel. The child then had a bulky faecal vomit and passed meconium for the first time. The result of the test was therefore inconclusive.

The gravity of the situation was explained to the parents and immediate operation advised, the diagnosis being intestinal obstruction due to a developmental defect.

**Operation.**—At 11.45 p.m. on June 20 the operation was performed under open ether by Mr. Young, with Dr. Divine as anaesthetist. A right paramedian incision was made, and some free fluid was found in the peritoneal cavity. The duodenum and upper part of the small intestine were very dilated and engorged. Evisceration of the small gut showed that the small intestine was twisted in a clockwise direction owing to non-descent of the caecum. The bowel was rotated anticlockwise for two and a half turns, and the abdomen was closed in layers.

During the operation, which lasted twenty-five minutes, the child regurgitated faecal fluid and gave the anaesthetist cause for anxiety. The patient was put on intravenous drip saline and placed in an oxygen tent.

Apart from widespread oedema the child made an uneventful recovery and was given breast milk, obtained from the mother, after two days, being put to the breast after a further seven days. At three weeks the baby was only 1 lb. (450 g.) below birth weight. The oedema gradually disappeared, being probably due to the drip saline.

#### COMMENT

The diagnosis was not easy, especially in view of the vomiting of blood. Thompson (1940) in the description of a very similar case draws attention to the association of volvulus in the newborn with gross haemorrhage from the intestinal tract, leading to the belief that his case was one of haemorrhagic disease of the newborn. It was, however, successfully operated upon on the ninth day.

Buckley and Wells (1944) record five fatal cases in which the predominant symptoms were vomiting, visible peristalsis, and a bloody motion. They emphasize that "in a newborn infant where vomiting cannot be explained on the basis of cerebral haemorrhage or infection, torsion of the intestine must be con-

sidered seriously." They also mention that evisceration of the small intestine is essential to avoid missing the diagnosis and for the proper reduction of the volvulus.

Borow and Borow (1937) reported a similar case in a baby 4 days old, which they believed to be the first to be operated on successfully. The predominant symptoms were vomiting, the passage of mucus and blood, and distension.

The occurrence of persistent vomiting in the newborn in association with the passage of blood in the motion or blood by the mouth with or without visible peristalsis or abdominal distension should make the diagnosis of torsion of the intestine a big probability. Absolute constipation must not be depended upon. Abdominal distension and visible peristalsis are late although helpful symptoms.

I wish to express my indebtedness to Dr. Morton-Stewart, to Mr. Young, who performed the operation, and to Dr. Divine, the anaesthetist.

### The Use and Value of BAL in Gold Dermatitis

The drug BAL (2,3-dimercaptopropanol, British Anti-Lewisite) has been applied to the treatment of acute arsenical poisoning (*Journal*, Oct. 4, 1947, pp. 520, 536), and its use as a remedy for gold dermatitis has recently been reported in America (Cohen *et al.*, 1947; Regan and Boots, 1947). In all, ten cases of the latter were treated, nine successfully. The following is a brief record of a case of gold dermatitis, the successful treatment of which appears to be due to the use of BAL.

#### CASE REPORT

A woman aged 55, with a three-years history of rheumatoid arthritis, received a course of "myocrysin" (total of 1 g.) over a period of ten weeks, finishing on June 2, 1947. On June 6 there was slight generalized irritation of the skin. One month later an exfoliative dermatitis started on the face, and subsequently spread to the neck, scalp, forearms, hands, and feet; there was also a stomatitis with marked buccal ulceration. The rash was still spreading when she was admitted on Aug. 11. On Aug. 14 she was given intramuscularly, four-hourly for four doses, 2 ml. of 5% BAL dissolved in arachis oil containing 10% benzyl benzoate, and the following day 2 ml. morning and evening. On the evening of Aug. 15 her temperature rose to 100° F. (37.8° C.), and although she showed no other signs of intolerance it was thought safer to discontinue the BAL. The rash stopped spreading after the second day, and thereafter steady improvement took place. She was discharged on Aug. 25, with the buccal ulceration healed and the skin practically clear. Some pigmentation of the skin of the face was still present when she was seen in October.

Obviously no definite conclusion can be drawn from this case, but it is suggested that the use of BAL in the treatment of gold dermatitis is worthy of further trial.

A new pest in houses is reported by H. E. Hinton and A. W. McKenny-Hughes in the October *Monthly Bulletin* of the Ministry of Health and Public Health Laboratory Service. It is the New Zealand weevil, *Euophrys confinis* Broun, which was first found in this country in 1937. It has now established itself "in a number of localities in houses as well as out of doors." The weevil leaves a thin outer layer of the wood intact except for exit holes. The interior of the wood is filled with a series of intercommunicating more or less parallel galleries, which are partly choked with dry powder consisting of the granular faeces of the larvae. The damage is remarkably like that done by *Lyctus*. The larvae seem to feed only in dead wood that is attacked by fungi.

## Reviews

### VASCULAR DISORDERS

*Peripheral Vascular Diseases.* By Edgar V. Allen, M.D., M.S., F.A.C.P., Nelson W. Barker, M.D., M.S., F.A.C.P., Edgar A. Hines, Jr., M.D., M.S., F.A.C.P., with Associates in the Mayo Clinic and Mayo Foundation. (Pp. 871; 386 illustrations, 7 in colour. 50s.) London: W. B. Saunders Company. 1946.

The authors of this magnificent study of peripheral vascular disease dedicate it to George Elgie Brown and in doing so pay a glowing tribute to his memory. Between 1921 and his untimely death in 1935 George Brown carried out pioneer work on vascular disease at the Mayo Clinic; he had planned this book as a record of his experience, and his friends have completed the work in a manner that must have satisfied even his high standards. The book is an excellent guide to the literature of peripheral vascular disease, for it is clear that the authors have taken great care in every section to collect the relevant facts about the history of the subject and to summarize the development of the opinions on pathology and treatment that are commonly accepted at present. But its usefulness is much enhanced by the numerous references to what has been learnt by experience at the Mayo Clinic. In short, it is a comprehensive work of reference enriched by the personal opinions of an experienced group of workers who have had access to a very large amount of clinical material. Brief biographical notes, with portraits, adorn the appropriate chapter-headings in homage to the pioneers in this field—Raynaud, Jonathan Hutchinson, Thomas Lewis, Weir Mitchell, Virchow, Matas, Buerger, Halsted, and Welch.

It is so long since attention was first drawn to many of these diseases that it seems remarkable that we should have had to wait till comparatively recently for any substantial advance in knowledge of their nature and treatment. On the other hand, perusal of this book makes it only too clear that there are still great tracts of unknown territory to be explored. There are full accounts in the early chapters of the special methods used to investigate vascular disease, and the authors add brief comments upon whether they have found the tests to be helpful or not in their own hands. It is interesting, for example, and rather surprising, to read that they have found oscillometry to be of little use—certainly of much less assistance than to several investigators in Britain. The authors describe diseases of the arteries in great detail, and refer to many instances of rare conditions which have occurred among the large numbers of patients attending the Clinic. We are interested to learn that diseases which we see quite often are rarities to them—namely, primary thrombosis of the popliteal artery in young patients with otherwise healthy arteries, and erythrocytosis frigida, which to them is so unimportant that it is grouped with other manifestations of pernio. It is strange to find that they classify erythema nodosum, erythema induratum, and disseminated lupus erythematosus as forms of arteritis, and it is not quite clear why they do so.

There is a masterly analysis of the whole problem of thrombophlebitis, with special reference to post-operative venous thrombosis; this section in itself makes the book a desirable acquisition for every general surgeon's library. The authors describe the rational basis for anticoagulant therapy in full, but condemn the ligation of veins for thrombophlebitis. In spite of intensive study no simple method has been discovered of successfully treating the oedematous ulcerated leg following deep thrombophlebitis. The volume ends with a comprehensive review of the inflammatory and non-inflammatory forms of lymphoedema, with experimental observations and clinical and pathological findings, as well as a brief but adequate and well-illustrated section on the operative surgery of peripheral vascular disease.

There is no doubt that this will be regarded as the standard book of reference on diseases of the peripheral blood and lymph vessels, and the authors are to be congratulated upon a production which is both a worthy memorial to George Brown and a credit to the present staff of the Mayo Clinic.

J. PATERSON ROSS.

### SURGERY OF SOFT TISSUES

*Surgical Treatment of the Soft Tissues.* Supervising Editor: Frederic W. Baneroff, M.D., F.A.C.S. Associate Editor: George H. Humphreys, II, M.D., Sc.D., F.A.C.S. (Pp. 526. 244 illustrations. £4 10s.) Philadelphia and London: J. Lippincott Company.

Any work published under the supervision of a surgeon of F. Baneroff's standing is bound to be interesting. Any surgeon could read this work with interest and occasional profit, but it is difficult to understand what place it is intended to fill or what class of reader it is intended to appeal. The appearance of the cover suggests that it is one of a series on the whole surgical treatment, but the selection of subjects in this volume is eclectic rather than comprehensive.

The book discusses cancer of the skin and breast at length but not the surgery of sarcoma or the block dissection of glands in the neck. It describes the excision of branchial cysts and fistulae, but does not mention the thyroid gland. The book is chiefly on operative surgery, but there is a dissertation on chemotherapy which, though good in itself, is more suitable for a journal and already out of date. It should appeal to the postgraduate and experienced surgeon; but information on many of the more intricate operations on which they really need help is incorrect or incomplete. In the section on arteries, for instance, it discusses the technique of arterial suture without aid of a number of pretty but quite misleading pictures, nowhere do the illustrations or the author reveal or even suggest that the key to arterial surgery is eversion of the intima. Indeed, some figures, if enlarged, might illustrate intestinal suture, and the author makes the remarkable statement that a Connell (inverting) suture can be used for arterial anastomosis. The section on ligation of arteries contains all the old textbook exposures and none of those of Fiole and Delmas for the deeper vessels, on which every postgraduate would wish to be informed, while the advice to approach the innominate, subclavian, and vertebral arteries from the inner border of the sternomastoid without dislocating the clavicle or even dividing the scalenus anticus is positively dangerous. Like the current dogma, the book is excellent in parts.

HENEAGE OGILVIE.

### NAILING BONES

*L'Ostéosynthèse au Clou.* By R. Socur. (Pp. 132; 134 figures. 325 francs.) Paris: Masson et Cie. 1946.

Intramedullary fixation of fractures of the shafts of long bones is not a new procedure. It has been practised sporadically since the early years of this century, but its value was limited because biologically inert metals such as are now available for internal splinting had not reached a satisfactory stage of development. During the recent war Küntscher in Germany, and to a lesser extent Lambrinudi and Burns in Britain, practised this method and it now has an established, if limited, place in orthopaedic surgery.

In his monograph on the internal fixation of bones by nailing Dr. Socur gives a full account of the present state of development of this method of fracture treatment, based on an experience of 74 cases. In the first half of the book he describes the indications for and technique of medullary nailing as applied to each of the principal long bones, and discusses its advantages and disadvantages in each case. The material in this section is well arranged; there is much of interest and much that will be new to many readers. The impression is inescapable, however, that the author's vigorous enthusiasm for the method has sometimes influenced his judgment when defining its indication and scope. Thus, he claims that intramedullary nailing is superior to other forms of internal fixation—and often to more conservative methods of treatment—for almost all the diaphyseal fractures of the long bones. There will be disagreement here. Many readers will think that some at least of the cases which are described could have been treated as effectively, and possibly more simply, by other methods—sometimes even by non-operative methods. It is a dangerous policy (though one that is becoming too prevalent) to argue that a shortening of the stay in hospital or the achievement of earlier ambulation is in itself sufficient ground for advising operative treatment of fractures.

In the second part of the book the author discusses fractures of the neck of the femur, and he attempts to analyse the causes of non-union of intracapsular fractures. This problem has baffled surgeons and pathologists for many years and any new explanation must be seriously considered. Dr. Soeur's explanation, though of interest, is not at first sight convincing, and much further evidence is required before it can be completely accepted. It certainly does not justify his scathing and rather harsh denunciation of Pauwel's theories. Nevertheless, the book is well worth reading both for the information it contains and for the stimulus of the author's vigorously expressed ideas.

H. OSMOND CLARKE.

## CHEST DISEASE

*Diseases of the Chest. Diagnosis and Treatment.* By Archibald Reynolds Judd, M.D., F.A.C.S. (Pp. 638; 140 illustrations, 1 in colour. \$9.00.) Philadelphia: F. A. Davis Company (1914-16, Cherry Street). 1947.

Although this book purports to be a systematic manual of diseases of the chest there are some strange omissions from the list of contents. After 60 pages on the anatomy of the thorax and the physiology of respiration the author devotes 220 to pulmonary tuberculosis; of these, 66 are on diagnosis and pathology and the rest on treatment. The only sort of pneumonia that he discusses is the tularaemic variety. He does not mention asthma, and the discussion of pulmonary abscess and of bronchiectasis is sketchy. The standard of accuracy may be judged by the following quotation:

"Although the ductus arteriosus generally becomes obliterated after birth, it occasionally remains patent with the result that there is an excessive admixture of arterial and venous blood. The body becomes markedly cyanotic and life is threatened. The patient generally dies in infancy" (p. 31).

This error is repeated on p. 44, where the causes of anoxaemia are discussed as follows:

"They include inadequate ventilation of the lungs, insufficient available pulmonary parenchyma, reduced oxygen tension of the inspired air, or the blood may not be presented to the lungs for oxygenation as in patent ductus arteriosus."

Other examples of inaccurate or misleading statements are:

"Intrathoracic Pressures: Intrathoracic pressures refer generally to the pressure existing between the chest wall and the lungs, in other words to the intrapleural pressure, which is 4.5 to 5.0 mm. of Hg on expiration and 8.5 to 10 mm. of Hg on inspiration" (p. 45).

"Hydrogen Ion Concentration: Extensive experimentation has shown that there is a sensitivity of the breathing apparatus to changes in the pH of the blood. Increase in breathing rate may occur in the presence of either a shift to the acid or alkaline side of the normal pH level (pH=7.35 to 9.35)" (p. 54).

Similar inaccuracies continue throughout the book. The literary style may be judged from the following quotation:

"The physiology of respiration and allied studies has been the subject of intensive study and research since thoracic surgery had its inception" (p. 39).

In a discussion of the technique of artificial pneumothorax induction:

"The site of the initial injection of air, if located over an area of normal lung, will aid in preventing the development of an empyema in the event that the visceral pleura is damaged" (p. 190).

"The treatment of bronchiectasis by active surgical methods, including phrenic nerve interruption, pneumothorax, oleothorax, thoracoplasty, and lobectomy, has been discarded with the exception of lobectomy" (p. 323).

On p. 440, in the course of a discussion of fungus diseases of the lung, a condensed classification of all plants from algae to flowering plants is labelled, "Table XIII. Outline of Phyla Group of Fungi," with the preamble:

"The following outline shows more clearly the intimate relationship between the forms in which we are chiefly interested."

The reviewer feels that these quotations will indicate his views on the book more clearly than any explicit statement that he would care to make.

J. G. SCADDING.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Standard Methods of the Division of Laboratories and Research of the New York State Department of Health.* By A. B. Wadsworth, M.D. 3rd ed. (Pp. 993. 55s.) London: Baillière, Tindall and Cox. 1947.

A detailed description of laboratory techniques for the examination of pathological materials, preparation of vaccines and sera, and laboratory administration.

*Office Treatment of the Eye.* By Elias Selinger, M.D. (Pp. 542. 43s.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

An account of ophthalmological conditions that may be treated in the home, consulting room, or hospital out-patient department.

*Annual Review of Biochemistry.* Vol. XVI. Edited by J. Murray Luck et al. (Pp. 740. 36s.) California: Annual Reviews, Inc. London: H. K. Lewis and Co. 1947.

Includes papers on the metabolism of proteins and amino-acids, the chemistry of the hormones, on folic acid, and on antimalarial drugs.

*Aids to the Diagnosis and Treatment of Diseases of Children.* By F. M. B. Allen, M.D., F.R.C.P. 8th ed. (Pp. 268. 6s.) London: Baillière, Tindall and Cox. 1947.

Includes new material on erythroblastosis, the sulphonamides, and penicillin.

*Old People's Welfare.* Published for the National Old People's Welfare Committee. 2nd ed. (Pp. 72. 1s. 6d.) London: The National Council of Social Service. 1947.

A guide to clubs, hobbies, housing schemes, and social services for the welfare of the old.

*When You Are Old.* Published by the B.M.A. (Pp. 33. 1s.) London. 1947.

An illustrated pamphlet for the layman based on the report entitled "The Care and Treatment of the Elderly and Infirm" by the special committee of the B.M.A.

*Germany Revisited.* By Victor Gollancz. (Pp. 39. 9d.) London: Victor Gollancz, Ltd. 1947.

An account of the author's visit to Germany in August of this year.

*Surgery: A Textbook for Students.* By C. A. Pannett, B.Sc., M.D., F.R.C.S. 2nd ed. (Pp. 769. 27s. 6d.) London: Holder and Stoughton. 1947.

A short textbook of general surgery for medical students.

*Headache.* By L. G. Moench, M.D. (Pp. 207. 53.50 or 19s. 6d.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

An account of the various causes of headache, and their treatment.

*With Cradle and Clock.* By Knud Stowman. (Pp. 224. 9s. 6d.) London: Hurst and Blackett. 1947.

A novel about an obstetrician in 18th century New York.

*Experimental Physiology for Medical Students.* By D. T. Harris, M.D., D.Sc., F.Inst.P. 4th ed. (Pp. 299. 18s.) London: J. and A. Churchill. 1947.

Describes simple laboratory experiments for students; many illustrations.

*Guide to the Study of the Anatomy of the Shark, Necturus, and the Cat.* By S. Eddy, C. P. Oliver, and J. P. Turner. 2nd ed. (Pp. 115. 12s.) New York: John Wiley and Sons, Inc. London: Chapman and Hall, Ltd. 1947.

A guide to the dissection of the dogfish shark, the mud puppy, and the cat.

*Atlas of Outline Drawings for Vertebrate Anatomy.* By S. Eddy, C. P. Oliver, and J. P. Turner. (102 plates. 12s.) New York: John Wiley and Sons, Inc. London: Chapman and Hall, Ltd. 1947.

An anatomical atlas to be used with the preceding book.

*Recent Advances in Pathology.* By Geoffrey Hadfield, M.D., F.R.C.P., and Lawrence P. Garrod, M.A., M.D., B.Ch., F.R.C.P. 5th ed. (Pp. 763. 21s.) London: J. and A. Churchill. 1947.

Includes new material on epidemic hepatitis, nephritis, experimental cancer research, antibody formation, and silicosis.

The Royal Family and Lieutenant Philip Mountbatten, R.N.

(Dorothy Wilding)

## THE LOYAL ADDRESS OF THE BRITISH MEDICAL ASSOCIATION

*We print below the loyal address of the British Medical Association to His Majesty the King on the occasion of the marriage of Her Royal Highness Princess Elizabeth to Lieutenant Philip Mountbatten, R.N., on November 20, 1947.*

To the King's Most Excellent Majesty:

The Humble Address of the President and Members of the British Medical Association.

May It Please Your Majesty.

We, Your Majesty's dutiful and loyal subjects, the members of the British Medical Association distributed throughout Your Majesty's Commonwealth and Empire, humbly tender to Your Majesty, and to Her Most Gracious Majesty the Queen, Congratulations upon the Marriage of Her Royal Highness the Princess Elizabeth with Lieutenant Philip Mountbatten, R.N., which we fervently hope may be attended with every happiness.

We desire also to give expression to our fidelity and loyalty to the Throne and our hope that Your Majesty's beneficent reign may long continue.

Signed on behalf of the British Medical Association:

HUGH LETT, *President.*

H. GUY DAIN, *Chairman of Council.*

J. B. MILLER, *Chairman of Representative Body.*

JOHN W. BONE, *Treasurer.*

and a credit to the present state

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 15 1947

## THE ROYAL WEDDING

The medical profession has always been stoutly loyal to the Throne, a loyalty that was exemplified by the greatest of all British medical men, William Harvey, who remained with Charles I when he was besieged at Oxford. The Throne has responded to this feeling of loyalty by taking through the centuries a close concern in the problems and work of the medical profession. Henry VIII played a notable part in regulating the practice of medicine, in founding the Royal College of Physicians, and in bringing the Barbers and Surgeons together in one corporation. In recent history the Throne has endeared itself to medical men and women through more personal acts and trials. Queen Victoria set a courageous example when she received at the hands of John Snow chloroform during the birth of two of her children. Her son, Edward VII, uttered his famous aphorism about the prevention of tuberculosis, and his interest in medical work is commemorated in the King Edward VII Welsh National Memorial Association (for tuberculosis) and the King Edward's Hospital Fund. Perhaps, on its part, the medical profession has rarely felt more closely attached to the Throne than during the long and grave illness of King George V, cared for by a team of medical men working under that devoted and great doctor the late Viscount Dawson of Penn.

So it is with more than ordinary feelings of patriotism and loyalty that the medical profession of Great Britain and Northern Ireland now extend their respectful greetings to the heiress-presumptive to the Throne. Her Royal Highness Princess Elizabeth, on the occasion of her marriage to Lieutenant Philip Mountbatten, R.N.

The British Medical Association has presented to its Royal Patron, His Majesty the King, a loyal address in commemoration of the marriage of his daughter. The wording of the address is printed opposite this page. The address itself is illuminated

on five pages of hand-made paper in full colours and gold, with the monogram of Princess Elizabeth and Lieutenant Philip Mountbatten and the device of the British Medical Association on the first two pages. The address is bound in padded blue Levant morocco bearing the device of the British Medical Association tooled in gold. The members of the British Medical Association are distributed throughout the Commonwealth and Empire, and so the Loyal Address thus humbly presented has more than a local and national significance. To the Nation's wishes for the happiness of the Royal couple we would add the special wish of the medical profession that they may long enjoy years of good health.

## THE MINISTER POSTPONES DISCUSSION

After the *Journal* had gone to press last week the Negotiating Committee was informed that the Minister wished to postpone to Dec. 2 and 3 the meeting with it which he had agreed should be on Nov. 11 and 12. A printed slip conveying this information was inserted into copies of the *Journal* circulated in Britain. While we may understand that the Minister needs more time to consider the very many points that have been discussed with the officers of the Ministry by the various subcommittees of the Negotiating Committee the postponement will disappoint the medical profession, which, it is clear from our correspondence columns, is anxiously awaiting the results of the deliberations and is uneasy at the silence prevailing during the past few months. A small point, but perhaps not negligible, is the fact that, the date of the meeting having been agreed by the Minister of Health, the members of the Negotiating Committee, who come from different parts of the country, had already made arrangements for their work to be done this week so that they could attend the meeting in London. The points brought forward for discussion by the six subcommittees of the Negotiating Committee have ranged over a wide field, and the Minister has presumably been kept informed by his officers of the nature of these discussions during the past few months. In order to avoid any ambiguity in the matter the Negotiating Committee drew up a carefully considered statement on the discussions so that the Minister could have this as well as the account provided by his own officers. The Negotiating Committee's statement and the Minister's reply will be published in the *Journal* as soon as the latter is received.

Dr. H. Guy Dain, Chairman of Council of the B.M.A., made a short but important statement at the meeting of the Panel Conference on Oct. 30, which was reported in the Supplement of the *Journal* of Nov. 8. In this speech he drew attention to some of the matters to which the Negotiating Committee had given much thought. He pointed out that the Minister had accepted the terms upon which it had been agreed to enter discussions—namely, that

the possibility of an amending Act should not be ruled out. Dr. Dain referred in particular to the obscurities of Section 35 of the Act relating to partnership agreements. In his own words "Section 35 of the Act is entirely unworkable." The Minister may agree that this Section can be made workable only by amendment. Another matter referred to by Dr. Dain was the buying and selling of practices, and the fact that he referred in particular to this problem suggests that the interpretation of the Act in relation to this is one which offers some difficulty to the Ministry of Health as well as much concern to the medical profession. Another matter of grave concern to general practitioners is the method of remuneration in the new National Health Service. Is this to be by capitation fee alone, or by capitation fee plus basic salary? This question is itself linked with the buying and selling of practices and the method of securing an even distribution of medical skill throughout the country. With this, too, is bound up the question of what is euphemistically described as negative direction.

Dr. Dain concluded his speech by assuring the Panel Conference that there had been no departure from the principles for which they stood. He referred to the forbearance of the profession in the months during which they had been unable to receive any information. The silent period is now coming to an end, and the next phase of events will soon be upon us. If the Minister of Health finds it impossible to reach a compromise on matters which the medical profession considers to be fundamental, then by further discussion and plebiscite medical men and women will have to decide what action to take. The plea for unity has been made often enough in these columns, but even though the plea now tends to become commonplace we would make it once more, because if the profession is divided against itself then the Minister of Health will have his way. But if the medical profession can sink what are in effect small, but at times irritating, differences of opinion, and can be united in its adherence to those principles which it knows are fundamental to the good of the profession and so to the good of the public, then the final outcome cannot remain in doubt.

## RISKS OF RADIOACTIVE ISOTOPES

Probably the most important influence that the recent developments in nuclear physics will ultimately have on medicine will result from using isotopic tracers, both radioactive and non-radioactive, in research. The first occasion when radioactive isotopic indicators were used in medicine appears to have been the investigation, published in 1924 by Christiansen and others,<sup>1</sup> into the absorption, distribution, and excretion of bismuth in the treatment of syphilis. Informative accounts of the use of radioactive and stable tracers were published in 1946 by Hevesy<sup>2</sup> and by Rittenberg and Shemin.<sup>3</sup> Dr. A. S. McFarlane in an interesting review in this week's *Journal*

(p. 766) calls attention to two important facts about the use of tracers in clinical investigations—namely, the plethoric safety of non-radioactive tracers and the need for caution in the use of radioactive tracers. However, says, "in the case of the radioactive tracers it is possible to employ such low concentrations that most of the experiments can be carried out with safety."

The risks of administering internally any radioactive substance must be carefully studied and estimated in each case, especially in connexion with the therapeutic applications of isotopes such as radiophosphorus and radioiodine. Mitchell has recently reviewed<sup>4</sup> the possible use of radiophosphorus in treatment. In a subsequent review the same writer emphasized the importance of avoiding the possible danger of carcinogenesis which might result from the introduction of radioactive materials, including radioiodine, into the body. During the last year it has become possible to estimate provisionally the therapeutic value of the few radioactive isotopes whose use depends upon their being selectively concentrated by the malignant cells, which are killed or damaged by the radiation. It is now evident, mainly from American work, that radiophosphorus,<sup>5-9</sup> and to less extent the radioiodine, may justifiably be given internally as therapeutic agents in suitable cases.

Radiophosphorus ( $P^{32}$ ) has a half-life of 14.3 days; it emits only beta particles, whose average energy is approximately 0.70 mev. It is usually administered intravenously in the form of isotonic  $Na_2HPO_4$  solution containing initially about 300 microcuries of  $P^{32}$  in 15–18 ml. of anhydrous  $Na_2HPO_4$  per ml. It can also be given by mouth, and it is then often assumed that 75% is absorbed. The clinical dosage of  $P^{32}$  has necessarily been decided on empirical grounds, and it is desirable to correlate it with the roentgen unit. It has been shown that 1 microcurie of  $P^{32}$  per gramme of tissue delivers a dose of 43–24 hours.<sup>10</sup> It is also important to know the differential absorption ratio—that is, the ratio of the concentration of the isotope in a particular tissue to the average concentration in the body as a whole.

Radiophosphorus has been used in the treatment of patients since 1936. The only disease in which it has yet been found to give better results than x-ray treatment is polycythaemia vera; it is probably the best therapeutic agent available for this condition, though general measures must not be omitted. In chronic myeloid leukaemia and chronic lymphatic leukaemia its effects and its limitations are probably similar to those of x-ray therapy. In cases of lymphosarcoma radiophosphorus is probably

<sup>3</sup> "Isotope Technique in the Study of Intermediary Metabolism," in *Currents in Biochemical Research*, edited by D. E. Green, New York, 1946.

beneficial than x rays. It is useless in acute leukaemias, Hodgkin's disease, and cancers generally. Whenever radiophosphorus is administered internally as inorganic phosphate its effects on the normal tissues must be considered, especially on the reproductive organs, the bone-marrow, the lymphoid tissue, and, when the expectation of life is considerable, the kidneys. It must be emphasized that all proliferating cells, both normal and malignant, concentrate the radiophosphorus by utilizing it as inorganic phosphate in the synthesis of complex compounds, including ribonucleic and thymonucleic acids.

These dangers are not hypothetical. Recently Platt, of St. Louis, has described<sup>17</sup> the histological changes produced in the organs of patients treated with radiophosphorus. In this series of 43 cases the diagnoses were: acute leukaemia, 4; chronic leukaemia, 21; leukosarcoma, 9; aleukaemic leukaemia, 1; Hodgkin's disease, 2; multiple myeloma, 3; lymphosarcoma, 1; melanoma, 1; and Ewing's tumour of bone, 1. In general the histological changes were similar to those caused by external radiation. Striking changes were of course found in the bone-marrow, lymph nodes, and spleen, although this organ was never reduced in size. Significant renal changes were observed and "can probably be attributed to the concentration that occurs in the nephron during the process of filtration and reabsorption." Minor histological changes that were probably radiation effects were also described in the brain, skin, oesophagus, gastro-intestinal tract, pituitary gland, adrenal cortex, lungs, and bones. "Finally, serious consideration must be given to the changes in the testes and ovaries of patients who are in the reproductive period of life. Observation of these organs confirms the possibility that spermatogenesis and oogenesis may decrease or disappear, with development of sterility in young persons given radiophosphorus."

In addition, as Dr. R. McWhirter points out (see p. 783), the question whether genes may be altered by radiophosphorus used in treating patients during the reproductive period of life must be considered. There is unfortunately little evidence on this subject. While it is possible to calculate the dosage of radiophosphorus which can be expected to deliver to the testis or ovary a dose of radiation not exceeding the "tolerance dose" of 0.1 r. (or, probably better, 0.05 r.) per day, it must be emphasized that there is almost no direct evidence from biological experiments with which to support such calculations. Another risk that may arise from the use of radiophosphorus in patients with a long expectation of life is that of late carcinogenesis—that is, the induction of leukaemias and bone sarcomas after a latent period of at least five years and probably much longer. We have no evidence on this subject, and clinical trials of P<sup>32</sup> have almost certainly not been carried out for long enough to reveal whether this occurs or not. Nevertheless, we may expect radiophosphorus to have a weak carcinogenic action. We conclude that in the present state of knowledge it is in general unwise to use radiophosphorus to treat patients who are in the reproductive period of life or who have an expectation of life of five years or more.

## PRICKLY HEAT AND TROPICAL ASTHENIA

Prickly heat or miliaria is a perpetual source of irritation and annoyance to the white man in tropical climates, and among the many remedies recommended there are none that receive much praise. Prickly heat presents a fine, superficial, vesicular eruption and erythema related to the sweat ducts, is readily evoked by exercise, and is associated with intense itching. It affects especially those parts of the skin which are normally covered, is aggravated by friction, and may last from a few days to a few weeks according to the severity of the attack. Numerous theories relating to diet, salt and water metabolism, and infection have been put forward to explain the disease, but none has proved satisfactory or established a basis for treatment. The late E. C. Smith,<sup>1</sup> of Lagos, cultured a monilia from the skin of patients suffering from prickly heat and claimed to have reproduced the disease in normal subjects by inoculation with these cultures.

Recently J. P. O'Brien<sup>2</sup> has made an exhaustive histological study of the disease and brings forward strong evidence to support the view that it results from the degreasing effects of the "civilized toilet" of the white man in relation to clothes, washing, the use of soaps, powders, and lotions, and the application of alcohol to harden and protect the skin from bites. The effect is to deprive the skin of its sebaceous secretion, with the result that a keratin ring closes the orifice of the sweat duct and a vesicle of sweat collects in the upper epidermis and provokes a secondary reaction. If an area of skin is smeared with anhydrous lanolin this horny occlusion is prevented, and exercise will now provoke profuse sweating over this area but no vesicular eruption; O'Brien calls this "the lipoid response." He suggests that a similar procedure in relation to the pilo-sebaceous orifices is responsible for acne and folliculitis, which are so often aggravated in the Tropics. In prickly heat a secondary parakeratotic reaction and plug-formation occurs beneath the vesicle and causes disintegration of the duct with obstruction to the flow of sweat, which then permeates into the tissues and may give rise to a vesicular reaction deeper than that of prickly heat and not accompanied by itching. This accounts for the persistent tropical anidrosis which follows prickly heat and may be associated with eczematous and sometimes exfoliative dermatitis due to the irritation of the extravasated sweat. Involvement of half the sweat glands of the body will impair adaptation to tropical conditions; involvement of two-thirds of the glands, O'Brien suggests, leads to severe impairment and asthenia. The asthenia is caused partly by pyrexia from interference with heat loss by sweat evaporation, and partly by the metabolic effects of the reabsorption of extravasated sweat.

O'Brien's histological studies and the results of his experimental investigation of 20 normal subjects appear to confirm his hypothesis. It should be easy to conduct a clinical experiment over a wide field and confirm or refute his findings. Natural cure results from exfoliation of the keratin plugs, and painting with 10% salicylic acid in alcohol for two to four days will cause effective peeling; the subsequent use of lanolin prevents relapses. For prophylaxis he advises loose, brief clothing washed daily, and inunction of the body with lanolin once a week. Soap should be used only once a day, hot water should be avoided, and powders should be applied only to the axillae, groins, and feet.

### "VISCOSE" HAZARDS

Since the first artificial silk fibres were made from nitro-cellulose by Chardonnet in 1890 the world's production has assumed a formidable tonnage, more than 65,000 tons in Great Britain and 334,000 in the United States in 1944. Of the various processes in operation, the "viscose" method is still the most widely used, accounting in 1941 for 89% of the world production, though the nylon process has rapidly become popular, especially in America, since 1939.

The health hazards associated with the manufacture of artificial fibre are greatest in the viscose process, owing chiefly to the use of carbon disulphide as the agent for transforming alkalized wood-cellulose into cellulose xanthate. This orange, syrupy, xanthate solution is "viscose," which after maturation and filtration is forced through spinnerets into an acid-saline coagulating bath from which emerge the precipitated filaments. During the spinning operation both  $\text{CS}_2$  and  $\text{H}_2\text{S}$  are liberated, and the higher the temperature of the spinning bath the higher the concentration in the air around the spin packages and the more important the ventilation of the machine.<sup>1</sup> Severe symptoms may follow continuous exposure to 30 to 40 parts per million of  $\text{CS}_2$  in the atmosphere, and the American Standards Association in 1941 set the maximum allowable concentration at 20 parts per million for a daily exposure of eight hours.

The provision and maintenance of efficient general ventilation of the workrooms is required in this country by the 1937 Factories Act, and the dangers of poisoning from inhalation and of the vesicant action of  $\text{CS}_2$  on the skin have to some extent been overcome by complete enclosure—in a closed circuit—of those operations in which  $\text{CS}_2$  is used.

In France<sup>2</sup> there has been a steady fall in the number of cases of fatal  $\text{CS}_2$  poisoning from 252 in 1942, and 166 in 1943, to 66 in 1944 and 62 in 1945, with a corresponding decrease in the number of serious though not fatal cases. Severe cases do still occur, however, and the most serious of all manifestations of poisoning—psychosis—was shown by six out of 100 cases reported in Italy<sup>3</sup> in 1946. In severe chronic poisoning, Parkinsonism, multiple sclerosis, polyneuritis, and muscular atrophy are some of the results of the toxic action of carbon disulphide on all nervous structures. Eye lesions due to affection of the optic nerve, papilla, and the retina, and also kerato-conjunctivitis, constitute a considerable problem; 600 cases were served in France in 1945. The prevention of all these toxic effects involves not only the engineering and hygienic measures already legally enforceable, but also the constant medical supervision and selection of workers in the artificial textile industry, and insistence that they take advantage of the protective clothing and equipment placed at their disposal.

### LIVER FUNCTION AND THYROTOXICOSIS

During recent years it has been increasingly recognized that in thyrotoxicosis, and more particularly in diffuse toxic goitre, the functions of the liver are frequently impaired. The hippuric-acid excretion and galactose tolerance tests are often abnormal in this condition, so that apart from its action in antagonizing the effects of the thyroid hormone the use of insulin with glucose in Graves's disease is further

indicated because of its therapeutic effect on the live A. W. Elmer<sup>1</sup> considers that the liver plays an important part in destroying the thyroid hormone, and that conditions in which there is increased thyroid secretion are aggravated by the decreased detoxication of thyroxine associated with liver damage. It does seem probable that many of the apparent anomalies of sugar metabolism and gastrointestinal function commonly met with in cases of thyrotoxicosis should be ascribed to a disordered liver rather than directly to thyroid dysfunction.

A recent paper by Eli Moschowitz<sup>2</sup> throws further light on the mechanism of these changes in the live. Moschowitz does not accept the view of F. H. Mills<sup>3</sup> or others that focal necrosis is a common finding, but he does agree that the formation of blood lakes is the primary histological disturbance. In his opinion these focal haemorrhages lead to fibrotic changes in the interlobular or portal spaces. While distinguishing the final picture from Laennec's cirrhosis and from changes due to bar pressure, he puts forward the suggestion that thyrotoxic cirrhosis, like that found in cardiac disorders, is due primarily to a circulatory upset. His contention, borne out by experimental evidence and excellent slides and diagrams, is that in hyperthyroidism the increased blood volume and the greater velocity of the blood flow through the hepatic artery cause a breakdown in the normal mechanism whereby the systemic pressure is adjusted to the lower pressure in the portal veins. Decompensation results in the formation of static blood lakes leading to fibrosis and finally to a fully established cirrhosis.

The analogy between this condition and that of chronic hepatic venous congestion is obvious, but the latter is to be regarded as an engorgement due to backward failure while cirrhosis in a case of diffuse toxic goitre is the consequence of forward failure. In the cirrhosis of cardiac failure the sclerotic changes are seen around the central hepatic vein; in the case of toxic goitre they are found in the interlobular area and more markedly in the subcapsular zone.

Moschowitz does not accept the idea of a common toxic factor attacking both liver and thyroid. Alterations of similar type can be produced in the liver in experimental hyperthyroidism, where no toxin is involved, so his contention that the pathology rests on changes in haemodynamics appears to be reasonable. This is a most interesting paper with numerous references and a good historical survey, and since it would seem possible that similar vascular disturbances may play a part in some forms of renal and pulmonary disease the theory put forward merits careful consideration. Purely from the clinical standpoint it serves as yet another reminder that in treating cases of diffuse toxic goitre the state of the liver should always receive due consideration.

### BRUCELLA INFECTION IN LABORATORY WORKERS

*Brucella melitensis* is a dangerous organism to handle in the laboratory. Early reports of infections in England and Malta directly traced to routine work or research with organisms of the brucella group were followed by accounts of similar accidents in many laboratories in Continental countries, and recently Meyer and Eddie<sup>4</sup> collected details of 74 cases from 17 institutions in the U.S.A. The victim

<sup>2</sup> Aubert, J., *Arch. Mal. Prof.*, 1946, 7, 181.

<sup>3</sup> Vigliani, E. C., *Med. d. Lavoro*, 1946, 37, 165.

<sup>1</sup> *New Engl. J. Med.*, 1939, 221, 927.

<sup>2</sup> *Arch. Intern. Med.*, 1936, 78, 477.

<sup>3</sup> *Med. J. Austral.*, 1942, 1, 195.

<sup>4</sup> *J. Infect. Dis.*, 1941, 62, 24.

are usually bacteriologists, pathologists, or technicians handling specimens or cultures, but the list includes animal caretakers, persons cleaning glassware, porters, and maintenance staff. Infection is usually due to some failure of technique, and one of the greatest dangers is thought to be the preparation of bacterial suspensions, an opinion which can readily be believed by those who have seen the high-speed flash photographs by Johansson and Ferris<sup>5</sup> of droplet-sprays produced by pipetting operations. Faulty methods for dealing with discarded cultures may be a source of danger, and the possibility of dust-borne infection must not be overlooked.

A recent description by Howe<sup>6</sup> and his colleagues of the occurrence of laboratory infections in seventeen young research workers at Camp Detrick, Maryland, is of considerable interest because of the unusual opportunities of obtaining data before infection and during the course of illness. The types of disease produced by the two infecting organisms, *Br. melitensis* and *Br. suis*, were not clinically distinguishable. It is likely that the risk of serious infection with *Br. abortus* is rather less than with the other species.

The constant features of the illness, which became established after a prodromal period of less than a week, were acute, moderately severe fever of irregularly intermittent type, marked fatigue, headache, and dull intermittent pains in the muscles and joints. Rigors, gastro-intestinal disturbance, and photophobia were not infrequent. The febrile episodes ranged from one to five, with two as the most usual number. There were no useful physical signs, and diagnosis was made by blood culture and the agglutination test. A curious observation was the frequent occurrence, some time after the onset, of erythema and oedema at the site of previous brucella skin tests and vaccinations. Illness was usually followed by a long period of lassitude and incapacity, of the same order as that reported by Meyer and Eddie, whose figures show a duration of over three months in half of their cases and of two to ten years in six cases. Treatment with sulphadiazine (alone and with penicillin) and with streptomycin produced little or no clinical evidence of benefit.

A safe and effective immunizing agent would be of great value. In view of veterinary experience it is not to be expected that brucella vaccines killed by heat or chemicals would be efficacious, and attempts to protect monkeys against *Br. melitensis* by live vaccines of *Br. abortus* have not met with success. All the patients in the Camp Detrick series had previously received a brucella vaccine the nature of which is not stated. In our present state of knowledge measures for prevention of these laboratory infections, which carry such a risk of physical and economic disability, must comprise the use of rubber gloves, scrupulous attention to technique, and measures for the control of dust-borne and droplet infection, including masks and possibly special inoculating boxes such as have been used for work with rickettsiae.

### SUBNORMAL INTELLIGENCE

Follow-up studies are perhaps one of the most valuable methods of investigation we have, although in the realm of child psychiatry they are all too few. It is unusual for the child psychiatrist to see his patients again after they reach the age of sixteen, so that in the ordinary course of his practice he does not learn the significance for adult life of the psychological deviations of childhood. For this reason an investigation in Stockholm of the after-history

of children educated in special schools for the retarded is of unusual interest.

Dr. Ramer<sup>1</sup> began with 389 boys and 237 girls, born between 1905 and 1917, who received special education of this type. They were compared with an almost equal number of boys and girls, born during the same years who had been taught in normal classes. By using every form of social agency he was able to follow their careers up to the ages of 26-35. The special-class students had an average intelligence quotient of 78 for the males and 77 for the females. Those who could be retested in adult life showed no change in their intelligence. This finding emphasizes the empty optimism of the term "mental retardation." In this section of the population—estimated to be 2-3% of the whole—the growth of intelligence is not so much "retarded" as limited from the beginning. The parents of the special-class pupils were of a lower occupational standard than those of the control group, and financial standards were also lower. In these children focal abnormalities were common: defective sight was present in 13%, defective hearing in 12%, and there were other neurological signs in 6%. Even at these early ages in the males mortality was higher than in the control group. Sexual adjustment also differed; at the time of the inquiry 50% of the special group were married, as against 64% of the control group, and the divorce rate was two-and-a-half times as great. Significantly fewer of the special group were employed on skilled work.

Figures relating to the receipt of public relief are also interesting. In the special group nearly two-fifths of the males and one-third of the females had been in receipt of relief, as against one-fifth of the males and one-eighth of the females in the control group. The rates for admission to mental hospitals were considerably higher in the special than in the control group, but the difference is almost exclusively made up by admissions for imbecility: there was also a somewhat higher incidence of schizophrenia, but the numbers are small. There is no strong evidence that the subnormal in intelligence are specially liable to the psychoses. Neither, surprisingly, do they seem to be specially liable to convictions for crime, vagrancy, and inebriety. The chances of being sentenced for a criminal offence before the age of 35 were exactly the same in the two groups. Nevertheless, those of the special-class students who had been marked by their teachers as "moody," and still more those who had a school record of truancy or pilfering, had criminal records, respectively, twice and four times as high as in the control group. There was no difference in the types of crime, and crimes of violence were rare in both groups.

These findings are of considerable interest, and to some extent run counter to those of previous workers. They suggest that the defects of the intellectually subnormal are largely limited to the field of intelligence, and that they should not be regarded as necessarily inferior in temperament and character.

Dr. E. R. Boland, F.R.C.P., will deliver the Croonian Lectures on "The Administration of Medicine" before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday, Nov. 18, and Thursday, Nov. 20, at 5 p.m.

The next session of the General Medical Council will open on Tuesday, Nov. 25, at 2 p.m., when the President, Sir Herbert Lightfoot Eason, will take the chair.

## THE HEALTH OF AUTHORS

### THE LLOYD ROBERTS LECTURE

Before the Royal College of Physicians on Nov. 11 Mr. Harold Nicolson gave the Lloyd Roberts Lecture for 1947 on the health of authors. In this lecture, he said, he would be more concerned with the mental health of authors and with that form of nervous activity which enabled its possessor to receive "intimation" and "inspiration." He restricted himself to those writers who could justly be called creative.

#### Bodily Health

Mr. Nicolson dealt with the popular fallacy that creative writers, and especially poets, were of weak bodily constitution and as such liable to premature death. He admitted that in the 19th century a high proportion of creative geniuses succumbed to tuberculosis, and mentioned the names of Keats and the Brontës. Yet examination of the mortality statistics of eminent writers did not show that their bodily, as distinct from their mental, health was any less than that of their illiterate contemporaries. The thirty-two most famous British poets who flourished between the middle of the 14th century and the end of the 19th century were remarkable for their longevity. Of these thirty-two, ten lived beyond the age of 70, nine died between the ages of 60 and 70, seven between the ages of 50 and 60, two between the ages of 40 and 50, and four under the age of 40. Many of these great poets did not take that care of their health recommended by their medical advisers. Ben Jonson and Michael Drayton were of a convivial disposition, yet the former lived to the age of 65, and the latter to the age of 68. "Herrick and Marvell were not particularly austere, yet each of them lived to over 70. Swift and Dr. Johnson during their lifetime were tortured with the dread of premature decay, yet Swift retained his bodily health at least until the age of 77, and Johnson was 75 at the time of his death. Tennyson again, who during his middle life was a confirmed hypochondriac, lived to the venerable age of 83; and Swinburne, whose early manhood was not distinguished by any pronounced asceticism, lingered on at Putney until his 74th year." Of the "four mighty poets" who suffered an untimely death, Keats died of consumption in Rome at the age of 26, but the deaths of Marlowe and Shelley were due to accident. The fourth of these poets, Byron, died from an accident at the age of 36. Mr. Nicolson dealt with the allegation that Byron might have survived to old age had it not been for the incompetence of the local doctors at Missolonghi. According to the accepted story Byron died of rheumatic fever brought on by rowing in an open boat across the lagoon after being heated by riding and drenched by a thunderstorm. His doctors were accused of failing to diagnose the illness, and of having bled him to death. Mr. Nicolson said he had made a special study of Byron's last illness, and, according to the experts he had consulted, Byron's final illness must have been either typhoid or "pernicious malaria."

Mr. Nicolson concluded that the bodily health of authors is as sound as that of any other calling.

#### Mental Health of Authors

There was, he continued, a theory that there was some special connexion between literary genius and mental derangement. It was true that a few creative writers had in their later years become demonstrably insane "... but it is not in the least true that all creative writers have been mad all the time." As authorities for "this distressing theory" Mr. Nicolson quoted Plato, Burton, Shakespeare, Dryden, Macaulay, and Lamartine, who spoke of "that mental malady which men call genius." Writers were themselves largely to blame if the general public regarded them as unbalanced. "In their lack of reticence, in their self-conscious habit of examining their nerves in public, it is they, rather than the outsiders, who have created the legend of their instability." As an example of the length to which a legend could be pushed Mr. Nicolson referred to Mr. J. F. Nisbet's book entitled *The Insanity of Genius* published in 1891, and he quoted this passage from it: "Genius, insanity, idiocy, scrofula, rickets, gout, consumption, and other members of the neuropathetic family of disorders, are so many different expressions of a common evil—an instability, or want of equilibrium, in the nervous system."

Mr. Nicolson then went on to examine the evidence. Of the thirty-two famous British poets whose longevity he had commended only two became demonstrably insane. Swift, he said, was haunted by the spectre of insanity all his life; yet in fact he lived to the age of 77, and it was only in the last three years of his life that his intellect became clouded. William Cowper was the subject of recurrent fits of melancholia and suicidal mania from his 21st year; but he enjoyed long interludes of perfect sanity. Dr. Johnson, Mr. Nicolson observed, might be regarded as a borderline case. He suffered at times from auditory hallucinations, and had a dread of insanity. "He entrusted his secret to Mrs. Thrale, and whenever he felt that madness was approaching, he would persuade her to lock him in his room and it seems to place gyves upon his legs, and even to whip him with a rod." Johnson died of asthma and dropsy at the age of 75. As another case Mr. Nicolson instanced that of Southey, whose mind became clouded in his 70th year, twelve months before his death.

#### Eccentricity

Mr. Nicolson concluded, then, that the legend of mental illness among creative writers was to a large extent the fault of the writers themselves. "All writers, and especially all poets, feel it dull to be thought completely normal. They thus divulge and even display their eccentricities." He gave Shelley as an example and described him "as on the whole a sane and normal person." The eccentricity of Shelley took two forms. "In the first place he was a hypochondriac. All creative writers are hypochondriacs, since those of them who do not worry about the state of their bodies are certain to worry about the state of their minds." Mr. Nicolson described how on one occasion Shelley found himself in a crowded stage-coach opposite a lady with unusually distended legs. He had just been reading a book in which there was a description of elephantiasis. Shelley concluded that the disease must be contagious and that he had caught it from the lady in the coach, a delusion which persisted for several weeks. Shelley's other eccentricity was that of "spectral and auditory hallucinations." On one occasion he saw a baby rise from the sea and clap his hands at him. One could account for these departures from reality, Mr. Nicolson said, only by considering in what manner creative writers were inspired. "Inspiration is a sudden flash or fusion between sense and fantasy, between reason and imagination." The illusions or hallucinations of creative writers were merely the tricks which a strong imagination was all too apt to play.

#### Temperament

It would be an error to regard all authors or even all creative writers as constituting a uniform category or type. They displayed an astonishing diversity, even in their methods, their hours of work, and their habits. Some writers, such as Wordsworth, could only bring their work to completion "by agonized plodding along a single road." Others preferred a variation of theme. Jane Austen, for example, kept *Sense and Sensibility*, *Pride and Prejudice*, and *Mansfield Park* in various stages of completion and would pass from one to the other. Thackeray found that his ideas flowed more freely in the "congested, if somnolent, atmosphere of the Athenaeum Club." Byron could work well only at night. Voltaire did most of his dictating from his bed. Victor Hugo composed some of his loveliest lyrics when sitting on top of a bus. Milton said that he could write really well only between October and March. Tennyson was more often inspired during the spring and summer. "Schiller found it necessary to stimulate his unconscious by keeping rotten apples in the drawer of his writing-table." Mr. Nicolson quoted these divergences to indicate that if there was such a thing as the literary temperament it assumed the most diverse forms.

#### Inspiration

If there were divergences in the practice of writing, there was general agreement among authors on the nature of inspiration. "Almost all writers who have ventured to express views upon this intricate matter are agreed that inspiration is an event which has no apparent connexion with conscious thought." "It comes," said Thomas Gray, "as the maggot bites." Inspiration was not only extraneous to the person, but was irresistible. "Almost universal also," Mr. Nicolson said, "is the sense of loneliness, abandonment, failure, and pathetic

incompetence which assails creative writers when the fleeting intimation has passed by." And so some of them to recapture inspiration resorted to stimulants, opiates, or narcotics. Others relied upon what Mr. Graham Wallas had called "unconscious cerebration." Mr. Nicolson said that it was doubtless with the idea of the value of unconscious cerebration that the late Lord Balfour used to recommend to those of his staff suffering from overwork a three-days course of detective novels and champagne.

#### Conclusion

Mr. Nicolson therefore concluded that so far as bodily health was concerned the author was neither more nor less healthy than any other sedentary individual. The creative writer, however, possessed "a certain special nervous sensibility." Genius was neither "a great aptitude for patience" nor "a transcendent capacity for taking trouble." Genius, said Mr. Nicolson, was "a spontaneous activity of the cells and fibres of the brain whereby new combinations of impressions are constantly being formed." Yet there was during moments of inspiration "some flooding of the conscious by the subconscious, and therefore some dissociation from reality." All authors were not of the same value or endowed with comparable talents. At the bottom of the scale there were those who with a certain capacity for observation and narration could notice and annotate the world around them. "Such writers are as happy and unperturbed as water-beetles jerking with long prehensile legs along the surface of the village pond"; and of those in the higher scale Mr. Nicolson said this: "Raised above all others, living in a rarefied ether of their own, confused by the eternal dissonance between the ideal and the real, the mighty poets are a race apart. For them imagination is no happy mood but a superb and agonized bewilderment. Not for them are the tiny pleasures, the small disappointments, the trivial success and failure, of the lesser breeds. The God visits them, not amicably, but in a flash of flame and fire; and in the after vacaney they know that they have caught but a momentary glimpse of intimation; their triumph is clouded by the knowledge that their illumination has been so narrow and so short."

## CHLOROFORM ANAESTHESIA

### EDINBURGH CENTENARY CELEBRATIONS

To commemorate the centenary of Sir James Young Simpson's discovery of chloroform anaesthesia celebration ceremonies were arranged on Nov. 4 by the University of Edinburgh.

At a scientific session in the morning Dr. D. S. Middleton (Edinburgh) said that there was still a place for chloroform in special circumstances. As officer in charge of anaesthetics when a prisoner of war in Singapore, he had found that chloroform, used extensively and in difficult circumstances, was a safe agent within reasonable limits and if administered according to proper instructions. Points to note were the use of pre-operative atropine, the maintenance of a clear airway, adequate oxygenation, and avoidance of sudden changes in concentration. The depth of anaesthesia and the dosage required should depend on clinical appreciation and not on dials. Considering the appalling conditions of malnutrition and disease the fact that hundreds of operations were performed under chloroform anaesthesia alone, with very few fatalities, was a tribute to the safety of the drug in careful hands.

Prof. R. R. Macintosh (Oxford), in a paper on dosimetric apparatus for the administration of chloroform, reviewed the physical principles involved in the design of an inhaler to deliver a known concentration of chloroform vapour. Illustrated by lantern slides, the designs of various inhalers were discussed, ranging through the century from those of Snow, Clover, Waller, Goodman Levy, Marston, and Vernon Harcourt to the modern "E.S.O." (Epstein, Suffolk, Oxford) produced during the war for use by paratroops to supplement thiopentone. This apparatus was of strong compact design, constructed to deliver a known concentration of chloroform vapour at any temperature, whether in the Arctic or the Tropics. Although the use of chloroform was now limited, in special circumstances, as in a London "blitz," it was invaluable. For the future assessment of an anaesthetic the dosage and vapour concentration must be accurately known; too often a drug was blamed for failure, and not careless or inept administration.

Dr. John Gillies (Edinburgh) presented a statistical analysis of the present-day use of chloroform, based on replies to a questionnaire sent to a large number of general practitioners in Scotland (all qualified at least seven years), and to specialist anaesthetists in this country and abroad. There were still a number of adherents to chloroform as an anaesthetic in general practice, particularly in obstetrics. Of 865 replies received from practitioners 94% favoured chloroform during labour. One point of interest noted was that, of the fatalities attributed to chloroform, twice as many were in those receiving atropine as premedication. In lighter vein, a series of amusing slides drawn by a colleague illustrated some of the reasons given for preferring chloroform: "less explosion risk," "more relaxation," "teaching purposes," and "surgeon's expressed wish." Summing up, it was recommended that as there was still a place for chloroform, particularly in general practice, its proper use should be taught to students, but as there was little opportunity for this in the modern anaesthetic technique used in surgical practice the proper place for such instruction was in the obstetric departments.

At a laureation ceremony to mark the centenary, Principal Sir John Fraser, Vice-Chancellor of the University of Edinburgh, said that the University was proud to honour the memory of Sir James Y. Simpson and his work for the benefit of medicine and humanity. The honorary degree of Doctor of Laws was conferred upon Dr. Henry Walter Featherstone, of Birmingham, founder-president of the Association of Anaesthetists of Great Britain, and upon Sheriff Thomas Blantyre Simpson, K.C., grand-nephew of the discoverer of chloroform anaesthesia.

In the afternoon a reception was held in the Upper Library of the University Old College, when Dr. Douglas Guthrie gave a brief and interesting address on the life and work of Sir James Simpson, and some personal relics were shown, together with items of historical and technical interest in connexion with the development of anaesthetics.

The social functions included a luncheon in the Senate Hall, and at night a dinner brought to an end the celebration of this centenary.

## LIVING CRYSTALS

The first of a series of open lectures arranged by the Edinburgh Postgraduate Board for Medicine was delivered at the Edinburgh Royal Infirmary on Oct. 14 by Dr. R. McWhirter, who in his paper on "Living Crystals" briefly described the nature of the structures acting as the carriers or vehicles of life.

In radiotherapy, he said, malignant cells were destroyed by the changes produced in those structures responsible for the maintenance of cell life, and a knowledge of the nature of those structures was essential to understanding the action of radiations. The simplest organism to study was the fertilized ovum, where the plan of each individual part of the adult organism was written in the genes. In the fertilized ovum of man there were 48 chromosomes, each containing approximately 1,000 genes, both chromosomes and genes being paired, each pair having a maternal and a paternal derivation. The combined action of a pair of genes determined a feature of the offspring. If a particular gene was damaged, that would result in a particular abnormality of the new individual. The permanence of gene structure must be inferred to account for the maintenance of the identity of race and species and for the expression of inherited characters in the adult organism, which was the product of 50 or 60 divisions of the original fertilized ovum. A gene was about 4 to 8  $m\mu$  in size, with a volume equivalent to about 1,000 atoms, and only by chemical combination of the atoms to form a molecule could permanency of structure be obtained. A gene was therefore a single protein molecule of about 1,000 atoms with the peculiar ability to reproduce itself exactly (each different gene forming a different molecule of constant structure).

The arrangement of atoms within molecules was constant, as was the position of each atom in a crystal. A molecule was the smallest possible crystal of a substance. A crystal increased in size by one molecule adhering to another, and the growth of crystals was not unlike a living process. The study of viruses had shown that they were similar in size to genes. A virus was a vehicle or carrier of life and could

reproduce itself exactly; it might therefore be described as a "naked gene." From pure cultures of viruses in solution crystals might be obtained, and several viruses had now been obtained in pure crystallized form (hence "living crystals"). It was conceivable that if genes could be obtained in pure form they too would be crystalline.

Genes had an effect on morphology and function, for they were not only able to reproduce themselves exactly but they could also act as models for the formation of allied molecules—i.e., enzymes or ferments, which were similar to hormones (produced outside the cell) and to vitamins (produced outside the body). These substances acted as catalysts and promoted the chemical changes which occurred within a cell. If gene structure was different, then the enzyme patterned on it would be different and new chemical substances would be produced—for example, in the colouring of hair. In phenylketonuria the genes which should produce the enzymes that oxidized para-hydroxyphenylpyruvic acid were absent, and the acid was not oxidized to a harmless substance but accumulated in the blood and cerebrospinal fluid, interfering with function and producing mental deficiency.

### Mutation

Changes in gene structure were rare. In any given gene one mutation in a million individuals was the approximate average mutation rate. X rays under favourable circumstances could increase this 150-fold. Unfortunately mutations were nearly always harmful and rarely beneficial to the organism, and, being commonly recessive, might not be detected until after several generations. So-called spontaneous mutations might be due to natural radioactivity or cosmic rays or to the disorderly action of heat in the tissues.

As radioactivity might produce mutations in gene structure, it was possible that the widespread use of radioactive isotopes without adequate care might cause considerable damage and pollution of the genes of a large section of the population. The effects produced would vary according to the damage done, and might produce sterility, abortions, stillbirths, and deaths in infancy. Diseases of genetic origin might also be increased, such as haemophilia, amaurotic familial idiocy, deaf-mutism, congenital cataract, and retinitis pigmentosa. Radioactive strontium could produce bone sarcomata, which had also been produced by radium and thorium. The difficulty was not overcome by using substances with a short period of radioactivity, for mutation was a single event and might be produced by radioactivity of short duration. Those were points of great importance to consider in the use of radioactive substances as tracers or in the treatment of diseases not commonly fatal, such as hyperthyroidism.

Radiology had made considerable contributions to the study of non-living material, where it had been possible to show the structure of atoms and of their nuclei. Further contributions to the elucidation of the problem of life might be as great. Atomic research had produced the deadliest of all weapons, the atomic bomb and its side-products, the radioactive isotopes. The damage done by the indiscriminate use of the latter might be less dramatic than that at Hiroshima, but it might be as disastrous.

## Nova et Vetera

### THE MEDICAL HISTORY OF EXETER

In the preface to his most interesting little book, *The Population and Epidemics of Exeter in Pre-Census Times* (James Townsend and Sons, Little Queen Street, Exeter), Mr. Ransom Pickard tells us that a mathematical Nobel Prizeman said the problem was very easy: "One had to find the number of births and deaths, the numbers going in and coming out, and the rest was a matter of addition and subtraction." In the ideal universe of the pure mathematician it would be easy, but that is not the world of the vital statistician. The master criminal in Mr. A. E. W. Mason's tale, *They wouldn't be Chessmen*, was foiled by the neglect of his subordinates to behave like chessmen: had our ancestors obeyed the orders of their rulers, if parish registers of christenings and burials had been complete and

enumerations of immigrants and emigrants been made, they reconstruct the population of any city at any time after masterful Tudors had ordered records to be kept would be a matter of addition and subtraction. Actually the records were incomplete. One large source of error was due to schism: many dissenters were not buried, or of course christened, clergy of the established Church; finally, no serious statistics of internal migration are available.

Statisticians from Rickman to Mr. Pickard have availed themselves of the fact that census-taking began nearly forty years before civil registration, so that over that period the record christenings, marriages, and burials kept by the Anglican clergy are printed in the census reports. Various ways of using the records were tried (the best account of these is that by the late Dr. J. Brownlee, published in the June and July issues of *Public Health* for 1916). If, for instance, one knows by enumeration the population of a town at the census of 1801 and again at the census of 1831, then, if there were no migration, the population in 1801 ought to be equal to that of 1831 plus the deaths in thirty years less the births. But the baptisms understate births and the burials understate the deaths, so each must be multiplied by an appropriate factor. Brownlee concluded when not a particular town but the whole country was in question the factor for burials was 1.2 and for baptisms 1.243. A still simpler method, favoured by Mr. Pickard, is to take the ratio of enumerated population to baptisms (corrected for omissions) for the census years 1801-41, and to use this as a multiplier for pre-census years. Two assumptions are involved—that neither the fertility rate nor the age and sex constitution of the population changed materially over the period under study. Migration, of course, is a complication. Working these lines, Mr. Pickard concludes that the population of Exeter in 1670 was between 18,500 and 14,400; his estimate, based on the mean values of the ratios of known census population to baptisms, is 16,100. If one applies the method of addition and subtraction to his means (his Table V) one reaches a somewhat larger figure. The lowest estimate by this method is a good deal larger than Macaulay's estimate of 10,000 (Macaulay does not mention his source) or that based on hearth tax records of a modern writer, Dr. Hoskins, who estimated the number of households in 1671-2 as 2,368 and the population as 11,200, i.e., used a multiplier of 4.74. Mr. Pickard rejects this multiplier as "obviously" too low; I am not sure about the "obviousness" of the multiplier, but it is rather larger than Gregory King (1648-1703) used for provincial towns, and Mr. Pickard's argument that *servants* had no *hearth* is not, I think, conclusive. The tax was levied on what we should call separate occupations or households: I suppose there might be occupants of rooms with no hearth who would escape notice, but hardly enough to bring the average size of a household from 4.74 to 6.8. But certainly 6.8 is not an impossible figure. John Graunt thought an average household in the City of London (within the liberties—i.e., the most densely populated area) had 8 members—husband, wife with three children and three servants or lodgers. However this may be, Mr. Pickard uses some of the hearth data skilfully. In four of the Exeter parishes—St. Davids, Sidwells, St. Mary Major, and Holy Trinity—in 1671-2 the mean number of hearths per family was 2.11, in 16 of the parishes 2.67. The first four parishes were, however, the most populous and their inhabitants poorer than elsewhere, as appears from other evidence. In his historical study of epidemics Mr. Pickard shows that the mortality rates of four parishes, on any reasonable assumption, must have been much higher than in the rest of the city, and he provides another example of social-economic contrasts. The decade 1741-50 was a grim one, particularly the year 1741, which followed two bad harvests.

Most of us know that smallpox was a deadly disease in the first half of the eighteenth century; it seems to have been particularly severe in Exeter. A citizen, John Score, who was sheriff in 1736, kept a diary and recorded in it illnesses in his family. Between 1711 and 1732, eight of his children had smallpox and one died of it. In 1729, when three of his children had smallpox, he notes: "The Small Pox was very fatal to us." Mr. Vivian lost all his children, being four sons. It is a combination of careful arithmetic with personal records which makes Mr. Pickard's monograph particularly attractive.

## Preparations and Appliances

### AN ENDOTRACHEAL FLANGE

Dr. JOHN GORDON, Esher, Surrey, writes: It is a common procedure in anaesthetic practice to have an indwelling endotracheal tube in position under the face-piece. The usual precaution taken to prevent the tube slipping into the lung is to fit a Rowbotham's angle-piece, but this has definite disadvantages. The end of the angle-piece may impinge against the side of the mask and become obstructed, or the exhaled gases may be directed over an eye, should these accidentally be included inside the mask. The practice of using a safety-pin damages the rubber tube, and the Woodfield-Davies tubes with the built-in rubber flange are not always to hand.

A set of four flanges has been constructed for me, one of which is here shown. In construction the flange consists of a circular metal plate,  $1\frac{1}{2}$  in. in diameter, perforated in the centre and fitted to a tapered corrugated tube. The plate has two small holes at opposite sides.

The advantage of these flanges is that they will fit any rubber endotracheal tube and are suitable for both oral and nasal intubation. They will not impinge against the face-piece and therefore do not become obstructed. The absence of any angle eliminates turbulent flow, and thus there is no additional resistance to respiration. The two holes serve as a guide to the position of the tip of the endotracheal tube in nasal intubation if the flange is fitted with the holes in line with the curve of the tube, and in oral intubation are used for the passage of tape, which is tied behind the head to anchor the tube.

These flanges have been made for me by Medical and Industrial Equipment, Ltd., of 12, New Cavendish Street, London, W. 1.

## Reports of Societies

### EPIDEMIOLOGY OF CHOLERA

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on Nov. 3 the problems of cholera control were discussed. Dr. W. S. C. COPEMAN, the president, said that on Sept. 22 it became known that five people in an Egyptian village had been admitted to hospital for what was taken to be food-poisoning. Within not much more than a month there had been several thousands of deaths from cholera in Egypt. This might prove to be one of the historic epidemics of the world. Two of the speakers in the discussion, Major-General Sir John Taylor, late of the Kassauli Institute, who had had vast experience of cholera in India, and Mr. P. Bruce-White, who had conducted bacteriological research in the subject, would within twelve hours be on their way to Egypt to endeavour to assist the authorities.

#### Problems of Cholera Control

Sir JOHN TAYLOR said that in India alone 200,000 deaths in a year from cholera had been recorded. So long as conditions continued as they were in the East there was always risk of spread to the West. In view of the control which it was now possible to impose, however, the danger of spread to this country was greatly minimized. The basic problem of cholera concerned the endemic centres; but for their existence cholera would die out. No full explanation of the special localization of cholera had as yet been given. A region might be said to be endemic when month by month and year by year over long periods deaths from cholera were reported. Such continuity was shown in Lower Bengal, where, in the 32 years for which figures were available, less than 30 months had been free from reported deaths. There was here a continuously

low level of incidence with, occasionally, a rise to epidemic level. In some areas where extremes of climate were considerable there were favourable seasons during which the disease appeared to die out, but here during such seasons cases were liable to be imported and the infection was carried over to the subsequent high incidence period. Some areas showed cyclical recurrences. Infection was maintained by a chain of human cases, convalescents or close contacts. The existence of an endemic centre was a source of danger to neighbouring areas. The obvious policy to adopt was to concentrate measures of control in the area in which infection was maintained. The matter was one which might well come within the purview of the World Health Organization with a view to co-ordinating measures where help was required. There was no short cut in dealing with this situation. There must be continuous improvement in general sanitation and water supply, and the difficulties of securing this could only be appreciated by those who had actually seen the conditions in the endemic areas.

Three main routes of extension from India had been recognized: (1) the long land route through Afghanistan and Iran; (2) the route by the Persian Gulf to Irak and on to Syria, Turkey, and the Mediterranean; (3) the Red Sea route to Egypt. Infection had not been carried to Europe by the first of these routes for many years, and the route did not at present constitute a major danger. The short sea journey from India was most serious in introducing these infections into Irak. That the disease should have been so introduced on eight occasions since the present century was sufficient to illustrate the danger. The danger of the Red Sea route arose from the multitude of pilgrims. A severe epidemic due to conveyance by this route occurred in 1902, with 34,000 deaths. He thought, however, that confidence might be felt in the quarantine measures now imposed on that route. An important point was the detention of pilgrims at the port of embarkation in India for five days before going on board ship, and the call at a port in the Red Sea. This had removed one of the greatest dangers of spread to Egypt and Europe.

On the question of the cholera carrier numerous observations had been recorded concerning the isolation of the vibrio from the stools of convalescents and contacts. Some of the earlier workers had reported intermittent isolation for several weeks or even months; but the question of the reliability of the serological diagnosis arose. The carrier problem in cholera had not the gravity which it possessed in, say, typhoid, and in practice infection from possible contacts or convalescents would appear to be small. Air travel, of course, introduced new complications. It was possible to travel by air from a centre where cholera was epidemic or endemic to almost any part of the world within the five days' incubation period, though as yet there was no confirmed evidence of cholera having been carried in this way. Air travel, as every passenger by an aeroplane knew, was by no means casual; it was surrounded by many formalities, and, moreover, it was possible to trace the movements of passengers. He concluded with a word of appreciation concerning the inoculation measures. Certain Indian statistics which he had seen but which were as yet unpublished confirmed the efficacy of inoculation.

#### Bacteriological Investigations

Mr. P. BRUCE-WHITE said that the problem of arriving at tests for invariably detecting cholera infection was twofold—namely, to devise means of identification of the cholera vibrio and other vibrios, and to find the organism responsible for cholera. The first was a laboratory problem; the second was only to be approached in close association with field studies. It could happen that the techniques with diagnostic sera in different laboratories applied to a single series of strains gave results widely at variance. It was these variations which led in the 'thirties to an international reinvestigation of the vibrio, its serology and relation to cholera. He summarized the work with which Gardner and he were associated in 1934-5. The vibrio, said Mr. Bruce-White, was a "sport." It kept to itself, through many tests, the secret of its pathogenicity. Even with the classical vibrio, the evidence of its prime role in cholera was circumstantial. After much work on the subject he came to the conclusion that in the field it might have some property lacking in the laboratory; but when visiting cholera wards in

Calcutta during the spring epidemic, when every bed was occupied, and when it was even said that the vibrio could be isolated from the saline transfusions, he inquired into ward infection among sweepers, ward attendants, and nurses, and was assured that there was none. Therefore his belief in a virulence factor which was lost in culture but present in the field was somewhat shaken. He could only conclude that the cholera vibrio as the primary cause of cholera did not hold good in quite 100% of cases.

Dr. ROSEMARY JACKSON gave the results of a small survey she had carried out on the distribution of vibrios in natural waters in this country. During the period October, 1945, to July, 1946, she examined over 40 samples from various sources, such as ponds, streams, natural lakes, and Thames waters, and succeeded in isolating vibrios from 75% of them. She thought that there was little doubt that if examinations were made at frequent intervals all such waters would be found to contain vibrios. From 30% of the positive samples more than one type of vibrio was isolated. Biochemical and serological tests were carried out on some 50 vibrios, and comparisons were made with the Indian and Far Eastern strains. The main biochemical points of interest which came out were that only three indigenous strains gave a positive cholera-red reaction; that 64% were of the Heiberg type; and that 50% were haemolytic, and the haemolysin was found to be both filtrable and antigenic. Serologically the vibrios were found to be heterogeneous in type and not related to Indian and Far Eastern non-cholera strains. One strain possessed the H antigen for *V. cholerae* and was also cholera-red positive, demonstrating once again the dangers inherent in using diagnostic cholera serum prepared against the whole organism.

#### Cholera Outbreaks in Great Britain

Dr. E. ASHWORTH UNDERWOOD gave a brief history of cholera outbreaks in this country. Asiatic cholera did not visit this island until 1831. Cholera reached Europe in 1829, and during the two following years it was widespread in the central part of the continent. In Britain much anxiety was felt. Indigenous cholera in this country, known as *cholera nostras*, resembled in certain features Asiatic cholera, and the question arose how medical men were to decide true cholera if and when it arrived. The Central Board of Health arranged for consultations with medical men who had had experience of the East. When Asiatic cholera did arrive, however, no one was left in any doubt. The first death occurred in Sunderland in October, 1831, and by the following Jan. 9 there had been 215 deaths from cholera in that town. Cholera next appeared in Newcastle in December, 1831, and spread to Gateshead and other Tyneside towns by Christmas. Middlesbrough suffered a devastating attack, and several other towns were stricken. The outbreak seemed to have exhausted itself in the early summer of 1832, but later it revived. In Glasgow there were over 3,000 deaths. The epidemic started in London in February, 1832, and dragged on until the end of the year. Three noteworthy outbreaks, either because of the havoc they brought or because they happened to have been well described, were at Exeter, where there were 1,100 cholera cases in a population of 28,000; Bilston, Staffordshire, where within a week of the outbreak, which lasted seven weeks, there were 150 cases; and at Dumfries in October, where there were 630 deaths in six weeks. The total number of deaths in the epidemic of 1831-2 was 21,000 in England and Wales and 9,000 in Scotland. There was a recrudescence in 1833 in London, but it died down, and cholera was seen no more in this country until 1848-9, when again many towns were heavily attacked. There were further epidemics in 1853-4, 1866, 1873 (only a few cases), and 1893, which was the last occasion when cholera obtained a foothold in Great Britain. Dr. Underwood mentioned that one result of the epidemic in 1848-9 was the foundation of the Prudential Assurance Company, as the result of some efforts by a Lambeth clergyman to insure his parishioners against the disease.

#### National and International Measures

Dr. MELVILLE MACKENZIE said that in this country the risk of an epidemic of cholera was generally very small, but there was always the possibility of an individual being flown from

Egypt and going to some village in England where perhaps the local practitioner had never even seen cholera and where the water supply was not satisfactory. No restrictions had as yet been put upon air traffic from Egypt. Inoculation had not been required, and reliance was placed entirely on the cards given out on arrival at the airport; but in view of one or two occurrences it was proposed to institute immediately a surveillance of all individuals who during the five previous days had spent one or more nights in Egypt. Another difficulty concerned various importations from Egypt, such as cotton and fruit, but the length of travel time by land and sea made most of the commodities safe.

In international work the World Health Organization had offered to buy cholera vaccine from different countries. An emergency meeting of the expert committee on quarantine had been held, at which an excellent statement was made on the position in Egypt and appreciation was expressed of the thoroughness with which the Egyptians were combating the epidemic. The Quarantine Committee had made a number of recommendations covering such questions as testing of vaccines and disinfection of aeroplanes. That week-end alone £5,000-worth of medical supplies and stores were being flown to Egypt; this included 3,000 syringes, in addition to a million doses of cholera vaccine. The difficulty was the lack of standardization of vaccine, a matter which the Quarantine Committee had referred to the Biological Standards Committee for consideration at its next meeting. Further epidemiological investigation was needed into the viability of cholera vibrios in sewage and also in fresh fruit and other commodities.

Sir LEONARD ROGERS, with the aid of maps, traced the course of various waves of cholera across India to other countries and also discussed the seasonal incidence. In the Punjab an epidemic resulting in 1,000 deaths might take place in October and die down in November, disappearing completely in subsequent months, but appearing again later. He described the Punjab areas as the real danger. General Sir JAMES HANCOCK said that he supposed the same principles governed anti-cholera work in Egypt as elsewhere, namely, disinfection of water supplies, attention to environmental hygiene, and inoculation. For his own part he had never had any doubt of the value of inoculation against cholera.

#### BRITISH FOOD RESOURCES AND REQUIREMENTS

A conference arranged by the Nutrition Society on "British Needs and Resources of Calories, Proteins, and Calcium" was held at the London School of Hygiene and Tropical Medicine on Oct. 25, with Mr. WALTER ELLIOT, M.P., as chairman.

#### Food Consumption

Mrs. M. C. BOWLEY, Dr. R. E. BRANSBY, Dr. H. E. MALTBY and Miss B. R. STANTON said that in calculating the national requirements for various foods their first step was to frame diets for representative individuals of the various groups arranged according to age, sex, and condition. These diets were planned to conform with British habits of eating when unhindered by rationing. At the same time they contributed sufficient calories, protein, calcium, and other nutrients to satisfy the recommendations of the Technical Commission of the League of Nations. The diets were based on conventional meal patterns and covered all food in natural or processed form eaten in the home or outside. Meat, fish, bacon, eggs, and cheese were included in amounts sufficient to provide a main dish in each of the three main daily meals throughout the week; milk and fruit were also to be provided in liberal amounts. The next step was to consult statistics on the proportions of the various groups in our total population and so to calculate the national requirements. The conclusion was reached that the fulfilment of the nation's demands would require a 48% increase in milk and its products above pre-war consumption, 56% in potatoes, and 27% in vegetables. Against these increases could be set a 14% decline in sugar, 5% in meat, and 6% in grain. By 1964 our needs for a

foods would presumably have increased considerably, with the demand for meat 50% and for potatoes 60% above the pre-war levels. The main difference between the present recommendations and those recently put forward by Leitch lay in the provision of larger amounts of meat, fish, eggs, potatoes, and fruit.

Mr. F. LE GROS CLARK commended the proposed diet for its variety and palatability, but questioned whether such a high allowance of animal protein was physiologically necessary. The food pattern chosen, moreover, differed from that adopted by the bulk of our population, particularly in regard to the evening meals. If rationing were stopped an increased consumption of sugar might be expected, while the sale of meat and other expensive foods would probably be related to prevailing economic conditions.

Prof. J. BEATTIE pointed out the difficulty of estimating the calorie requirements of adult subjects. In carefully controlled experiments in a German prison he had observed the effects of subsistence for four months on a diet which provided only 1,750 calories daily. The subjects, who did not work, all lost weight at first. Later, however, their weight became constant, with the return of a positive nitrogen balance and a considerable fall in the basal metabolic rate. Some of the prisoners were then given another 500 calories daily in order to find out whether this extra allowance would enable them to perform forestry work. The main effect of the supplement was to raise the B.M.R., and the men remained incapable of doing manual work.

Dr. E. C. OWEN remarked that the estimate of 1 g. daily for the calcium requirement, quoted by Dr. Magee and his colleagues, was substantially greater than estimates of 0.29 to 0.67 g. made by other workers. Age influenced the calcium requirement; the highest incidence of skeletal fractures occurred at ages 10-15 years. Another important factor was the vitamin D intake; in a well-known boarding school the incidence of fractures was greatly increased during the years 1918-22, when unvitaminized margarine was substituted for butter. In regard to animal proteins he suggested that their great biological value might be due mainly to a high content of lysine.

Dr. I. LEITCH observed that in comparing her estimate of the nation's food requirements with his own Dr. Magee had not made adequate allowance for the unaccountable discrepancy between estimates of food supplied and food consumed. With most foods the gap was about 10%, but there was too much variation for the same correction to be applied indiscriminately to all foods. Prof. J. R. MARRACK considered that agreement within 10% of estimates of food supplied and consumed was as good as could be expected in view of the low degree of accuracy of dietary surveys.

Dr. E. C. WOON said there seemed to be some danger of confusing the amounts of food necessary to conform to a conventional dietary pattern with those actually necessary to satisfy physiological demands. The national food requirements could be calculated in three distinct ways as: (1) the minimum amounts of each type of food necessary on a strictly physiological basis to maintain health; (2) the amounts of food which would be necessary to conform to some standardized food pattern; (3) the amounts which would be consumed if the whole population could choose and eat all foods freely, without being deterred by the need for payment.

#### Food Production

Dr. E. T. JONES, in a paper read by Dr. G. Bourne, discussed the production of cereals and root crops. While our home production of potatoes sufficed for human requirements, we grew sugar beet and wheat only sufficient for about one-third of our requirements. By more intensive cultivation the yield per acre of all these crops might be increased, and by diverting ground now used for potatoes to wheat or beet a greater contribution to our total calorie requirement might be obtained.

Prof. H. D. KAY dealt with milk production. The present output in this country corresponded to 0.62 pint (352 ml.) per head per day, whereas 0.77 pint (437 ml.) would be necessary to meet Dr. Magee's estimate of our requirements. In order to increase milk production the main essential was to provide more food, such as grain, bean meal, or oil cake, for

our present herds. More use should be made of artificial insemination by selected bulls to produce cows capable of a high milk yield. Such animals, however, required more food and more attention than ordinary cows.

Dr. J. HAMMOND told how the production of meat in Britain had declined in recent years. In 1932 we produced 30 lb. (13.6 kg.) of carcass weight of bovines per head of the population with 15 lb. (6.8 kg.) of sheep and 20 lb. (9 kg.) of pig—a total of 65 lb. (29.4 kg.). For 1946 the corresponding figures were 24 lb. (10.9 kg.), 8 lb. (3.6 kg.), and 6 lb. (2.7 kg.)—total 38 lb. (17.2 kg.). In order to produce more meat as a contribution to Dr. Magee's total demand of 146 lb. (65.7 kg.) per year it would be necessary to import more animal food-stuffs. One economical way of producing beef was to fatten the animals on the summer flush of grass, and then keep the meat in cold storage until required. Our sheep population was reduced from 26 millions to 18 millions as the result of the wartime agricultural policy, and a further 4 millions were lost in the blizzard early this year. In breeding sheep the Border Leicester, and other types which had a high incidence of twin lambs, should be encouraged. A few pigs should be kept on every farm to use up odd scraps of food.

Drs. R. J. H. BEVERTON and G. C. TROUT, discussing fish, said that before the war a typical annual catch was about 500,000 tons, including 137,000 tons of cod, 74,000 tons of haddock, 40,000 tons of hake, 33,000 tons of plaice, 10,000 tons of crabs, lobsters, and mussels, and the remainder mainly as herrings. In some instances these hauls were more than the fishing-grounds could sustain, and in the North Sea area in particular fish became scarce and small. Vast numbers of cod, however, were always available in the Arctic waters around Bear Island, and conditions nearer home had improved as the result of the interference with fishing during the war. The herring, which was of special value as a source of calories on account of its high fat content, had shown no signs of being over-fished, even in the North Sea. The main difficulty in taking full advantage of herring catches lay in the perishable nature of this fish, which should be consumed or preserved within 36 hours of catching. By greater exploitation of the herring and Arctic cod and with enlarged fishing fleets it should be possible to increase the total catch by 40% of the pre-war level, with a resulting contribution of over 6 g. of protein per head per day to the national diet.

Mr. E. T. HALNAN calculated that to satisfy Dr. Magee's estimate of our food requirements it would be necessary to provide 203 eggs per head of the population each year. The consumption for 1946, including dried eggs, was 180 per head, which meant that we were actually eating more eggs than before the war. Only about 80 of these eggs, however, were home-produced. There would be no difficulty in building up stocks of hens in this country if sufficient food could be obtained. Possibly some home-grown wheat and barley might be spared for poultry feeding. Plenty of wheat offals would, of course, be available for chickens if the extraction rate of flour were to be reduced to its pre-war level of 70%.

#### Discussion

Dr. W. K. SLATER expressed doubts as to the feasibility of increasing agricultural production to the extent advocated. Any further land put under cultivation must necessarily be of poor quality. Unduly intensive cultivation would lead to competition for materials and labour. Thus an increase in the sugar beet crop would demand additional labour besides capital expenditure in the erection of more factories. It would, moreover, be difficult to educate 300,000 farmers in the methods necessary for intensified cultivation.

Dr. NORMAN WRIGHT, who was recently appointed as Scientific Adviser to the Ministry of Food, spoke on the relations between overseas supplies and the home production of food, and emphasized the need to prevent waste. Dr. W. R. WOOLDRIDGE pleaded for more efficient action in preventing diseases in farm animals, and condemned the action of the Ministry of Food in importing the infected carcasses which gave rise to the present outbreak of fowl pest.

Prof. A. W. ASHBY, in a general survey of the day's proceedings, regretted that the activities of the Scientific Food Policy

Committee had been discontinued. He saw an urgent need for consultation between those who had given papers in deciding on the dietary standards which were necessary for adequate nutrition of the human subject. It was equally essential to discriminate between the rival claims of the various farm animals to share in such foodstuffs as were available.

### LUNG ABSCESS

At a meeting of the Manchester Medical Society on Oct. 1 Mr. W. F. NICHOLSON, reading a paper on this subject, said that bronchial obstruction with secondary infection was the common cause of lung abscess. In normal health the cilia lining the bronchial tree kept the air passages free from organisms and debris. When ciliary action was impaired by trauma, infection, or growth, coughing was effective in preventing bronchial obstruction. When coughing was embarrassed by pain or anaesthesia or tenacious secretion, bronchial obstruction might occur.

An abscess due to bronchial embolism was peripheral in the lung, though it might not present on the costal surface. Because the subapical segment of the upper lobe and the apical segment of the lower lobe contained the most dependent bronchi in the lateral and supine positions respectively, these segments were most frequently affected, and consequently most inhalation abscesses presented on the costal surface of the lung corresponding to these segments. The upper-lobe abscess was common after operations on the upper respiratory tract, in which a lateral position was usually employed in the immediate post-operative period. Lower-lobe abscess was often due to abdominal operations, which were associated with a supine or Fowler's position. A putrid lung abscess was frequently undiagnosed because it was still not widely known that such an abscess could exist without foul sputum. When the abscess ruptured into the bronchial tree sputum would be present; but even before this happened there might be fetid breath.

Treatment was by drainage, either bronchial (postural) or external (by operation). In either case location of the lesion must be exact if treatment was to be rational. The responsibility of the physician in these cases was heavy. If he delayed external drainage, in many cases the disease spread to a diffuse suppurative pneumonia of a lobe, which would eventually require a lobectomy. Moreover, the immediate mortality of conservative treatment was considerable. Only by sharing the responsibility with a surgeon from the beginning could drainage be instituted promptly in cases which did not respond to medical measures. Chemotherapy and antibiotics were of value, but did not replace drainage. Bronchoscopy was of value in locating the broncho-pulmonary segment of the abscess, in improving bronchial drainage, and in excluding a foreign body or growth; as a curative measure it was of little more value than postural drainage. Surgical drainage would decrease mortality and morbidity.

At a meeting of the Liverpool Medical Institution on Oct. 23, with the president, Dr. H. Wallace-Jones, in the chair, Dr. R. Lipman read a case history illustrating psychogenic factors in dysmenorrhoea, menorrhagia, and *Mittelschmerz*. Mr. Barry McMurray reviewed the various lesions which may occur in sprained ankles.

The autumn number of *Biology and Human Affairs* (obtainable from the British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1, 2s. 6d.) contains an interesting article by Prof. J. M. Mackintosh on "The Contribution of Science to Comfort in the Home." He comments on the delay between the discovery of knowledge and its application in the home—a popular topic of conversation among housewives after reading articles on the contributions that science could make to their comfort. He attributes it partly to the conservatism of builders, and to those people, often elderly, who choose designs for new houses for working people—"the cold, dead hand of a passing age presses too hard on an art that is coming to birth."

## Correspondence

### Anaesthesia for Head and Neck Surgery

SIR.—The article by Dr. J. G. Bourne (Oct. 25, p. 654) on the subject of thiopentone-nitrous-oxide-oxygen anaesthesia with curare for head and neck surgery will have been read with interest by all. May I trespass on your columns to say that my reaction was one of admiration for the obvious skill of the author? Following hard on this, however, I found myself asking, does this method in fact promote the well-being of the patient and constitute an advance in the degree of safety afforded to him, or does it rather represent an advance in the technical skill of the author? (For these two virtues, though usually so, are not invariably synonymous.) My doubts were increased when I saw that, in the five instances in which the advantages of the new method or the objections to the old were enumerated, on every occasion the time factor was given pride of place. The factors such as the degree of safety and the comfort or discomfort of the patient followed in (presumably) their due order. One cannot but gain the impression that the speed of the method constitutes its chief attraction in the author's estimate.

I also find it rather hard to agree with the statement that for procuring the initial relaxation for intubation there is no agent as safe as curare. I have yet to see the figures that will convince me that the dangers of a few ounces of ether are greater than those of 20 mg. of curare. The amount of ether required for a blind intubation (and in the majority of head and neck cases a nasal tube is as good as an oral) is not very large. If the head is not moved, anaesthesia can be maintained with a minimum trickle; and if it is possible to turn off the ether 10–15 minutes before the end, then the degree of post-operative nausea is but reasonably transient in most cases. That the degree of relaxation afforded by this method should be cited as one of its virtues caused me a mild degree of surprise, for I have worked with Continental as well as English surgeons (through circumstance rather than choice), and have never been asked, during a head-and-neck operation, for a degree of relaxation that would necessitate the giving of 20 mg. of curare.

Surely one of the advantages of curare is that it provides where needed a degree of relaxation that could otherwise only be brought about by some form of nerve block or the use of toxic amounts of the inhalational agents. Is, then, the method described by the author a logical outcome of this; or is it a very skilled demonstration of cracking a medium-sized walnut with an out-size sledge-hammer?—I am, etc.,

London, W.8.

G. C. STIRRI.

SIR.—I read with interest Dr. J. G. Bourne's article (Oct. 25, p. 654), and my purpose in commenting is to inquire rather than to criticize. Under "Method" the sequence enumerated appears to me to be capable of improvement both in the safety factor and in time. Would it not be better to adopt the technique for curare advised by Dr. Gray, of Liverpool, and to give the injections in the following order? (1) Test injection of "tubarine," 5 mg. (one-third average induction dose); (2) wait for four minutes to observe its effect, from which to judge the total injection dosage advisable, and then inject this—say, a further 10 mg.; (3) immediately give in a separate vein an intravenous barbiturate in adequate dosage.

By this time the patient will be ready for laryngoscopy, "cocainization," and intubation. Then N<sub>2</sub>O—O<sub>2</sub> may be continued, with a further relay of barbiturate if necessary at a later stage. By this there is not only a safer control of curare but also a saving of time, as the effect of both the tubarine and barbiturate synchronize.—I am, etc.,

Barton-on-Sea, Hants.

HAROLD C. J. BULL.

### All the Vitamins

SIR.—When you published Dr. Leslie J. Harris's article (Nov. 1, p. 681) in reply to a simply worded request in "Are Questions?" one expected a simple reply, giving the answer in words which the average doctor could understand. I wonder if the reader who sent that question is satisfied by Dr. Harris's

# Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis. It also causes bronchodilatation.

## Cardophylin

THEOPHYLLINE-ETHYLENEDIAMINE

**INDICATIONS**  
DISEASES OF THE CARDIOVASCULAR SYSTEM  
OEDEMA • ASTHMA

LITERATURE AND SAMPLES ON REQUEST  
IN TABLETS FOR ORAL USE, AMPOULES AND SUPPOSITORIES

MANUFACTURED BY WHIFFEN & SONS LIMITED,  
CARNWATH ROAD • FULHAM • LONDON • S.W.6.

The diagram summarizes the local and central actions of the drugs contained in 'Franol'. Clinical experience indicates that the combination gives more effective control than ephedrine and theophylline prescribed singly.

A noteworthy function of the 'Luminal' content is to allay anxiety: it keeps the patient physically and mentally at ease, inhibiting the sudden panic which sometimes precipitates an emergency call.

'FRANOL' (ephedrine + theophylline + 'Luminal') is available in packets of 20, 100, 500 tablets. The average adult dose is 1 tablet 4 times a day at the first warning of an attack.

## Nutritional safety during weaning

As the infant's introduction to solid food, and as a basis of the diet during the subsequent months, there is no more suitable preparation than Farex. The usual starchy predominance of cereals is balanced in Farex by an increased proportion of protein; in addition, Farex supplies minerals—assimilable iron, calcium and phosphorus—and a useful amount of vitamin D (1,000 i.u. per oz.). With Farex and milk as the staple ingredients, weaning to solids is reduced to its simplest and safest terms. Please help to ensure sufficient Farex for weanlings by advising it only for them.

GLAXO

CEREAL FOOD

Ready to Serve

Glaxo Laboratories Ltd. Greenford Middlesex BYRON 3434

Are you meeting with cases of malnutrition in your practice?

One ounce of Hepamino will supply	
PROTEIN	one-half the total daily requirement (providing the total daily requirements of essential amino acids.)
NICOTINIC ACID	twice the total daily requirement
RIBOFLAVIN	twice " " "
FOLIC ACID	twice " " "
PANTOTHENIC ACID	three times the total daily requirement
PYRIDOXIN	one quarter " " "
BIOTIN	the total daily requirement
INOSITOL	one eighth the total daily requirement

—and these are immediately available for biological utilization. Also present are iron and copper, vitamins B<sub>12</sub> and B<sub>6</sub>, purine and pyrimidine bases and anti-metabolic anamia factors. Hepamino is issued as a dry, granular powder in containers of approximately 5 oz. at 15/- each.

## Towards more NORMAL CONTROL

One injection of Globin Insulin (with Zinc) before breakfast controls the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal—the normal control of blood sugar. 'Wellcome' brand Globin Insulin (with Zinc)—originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York—is supplied in strengths of 40 and 80 units per c.c., each in phials of 5 c.c. Descriptive literature available on request.

## 'MYANESIN'

*The new muscle relaxant*

**NOW AVAILABLE**

Clinical trials, involving its use in over a thousand cases, have clearly shown the value of 'Myanesin' for relaxation of the abdominal musculature during surgical operations.

'Myanesin' was discovered in the B.D.H. Research Department. It is an entirely synthetic substance of known and constant chemical composition [ $\alpha$ :  $\beta$ -dihydroxy- $\gamma$ -(2-methylphenoxy)-propane].

'Myanesin' is now available as a 10 per cent. solution in ampoules of 10 ml. issued in boxes of 3 and 12 ampoules.

Like its widely used predecessors, this new 'Sollux' Lamp has interchangeable radiant heat and infra-red generators. Both give full therapeutic output of radiation, in a beam which can be closely regulated in intensity, direction and field of application. This new model embodies an improved finger-light vertical movement.

This unique combination of essentials has made the Sollux Lamp the accepted standard equipment for radiated heat therapy. Full guidance is given covering its application in pain, injuries, indications, and inflammation of all descriptions. You can obtain full details of the Sollux Lamp (Model IX) from our illustrated folder "Therapeutic Heat Treatment". Ask for leaflet M.161r.

article. Is he interested to know that  $\alpha$  and  $\beta$  carotene, kryptoxanthine, lepronene, echinenone, and myxoxanthine, etc., serve as provitamins for vitamin A? Does he find it easy to learn the eye changes of A deficiency when he reads that xerotic changes, Bitot's spots, xerophthalmia, and keratomalacia occur, or would he prefer to have a description of the appearance of the eye in less technical terms such as dry or scaly? Similarly with nicotinamide. Does it convey anything to the average reader to learn that it is a component of coenzyme I or "Euler's cozymase" diphosphopyridine nucleotide, and also of coenzyme II or Warburg's enzyme triphosphopyridine nucleotide? If the space taken by those words had described what the mental changes of pellagra are (we are told there are mental changes, but whether mania, depression, dementia, or hallucinations is not stated), would that have been more helpful?

No doubt the article is full of accurate and scholarly information to the advanced biochemist and nutritional research worker, but such persons have their special books on the subject and do not need to read it in the *B.M.J.* Surely your job as editor is to see that information and fact rather than incomprehensible words are dispensed to your readers. There is no mention of the fact that the teeth become loose and fall out in scurvy (though we are told the reversibly oxidized derivative dehydroascorbic acid is active in treating it), and nothing is said of the occurrence of the signs of riboflavin deficiency in the common iron-deficiency anaemia of women, though the occurrence of riboflavin as iso-alloxazine-adenine-dinucleotide is mentioned. One could go on indefinitely. Under vitamin D we do not learn whether it helps children to grow better teeth or not, but are enlightened about vitamin D, being irradiated 7-dehydrocholesterol (cholestadien-3-ol).

I am not criticizing the article itself, only your policy in printing it. If I am wrong in believing that less than 2% of your readers understand most of the technical terms, I apologize for unfair criticism, but if I am right, I suggest that you owe it to your subscribers to give them useful, understandable, and practical knowledge instead of allotof-words-2-obscure-4-any 1 2 succidin-understanding them.—I am, etc.,

London, N.W.10.

RICHARD ASHER.

\* The question asked was as follows: Q.—Please give a list of vitamins with all their different names and with notes on the signs and symptoms of deficiency [our italics]. It was assumed that medical men know the meaning of medical technical words such as xerophthalmia.—Ed., *B.M.J.*

SIR.—Those who have to keep pace with the literature on vitamins will best appreciate Dr. Leslie J. Harris's difficulty in attempting to compress even into three pages of the *Journal* the answer to the question about vitamins which a correspondent expected to appear as a brief reply in "Any Questions?" There are nevertheless one or two points in Dr. Harris's article which should, I feel, be slightly amplified. For example, Dr. Harris includes para-aminobenzoic acid ("paba") in his least significant group—viz., those vitamins needed by animals but whose significance for humans is uncertain. It has, however, been shown in several series of clinical trials<sup>1-4</sup> that paba in pharmacological dosage has a pronounced effect in the treatment of the rickettsial infections in man. The vitamin is listed in Appendix B in an M.R.C. report<sup>5</sup> among substances showing no activity in a 20-mg. dose given to a 15-g. mouse, but no human test on it is recorded in the report.

A further point which often arises occurs in connexion with the value of vitamin E in human abortion. As long ago as 1940 Bacharach demonstrated mathematically<sup>6</sup> that the probability of the results obtained with it in the treatment of a series of 42 patients, who had had four or more abortions, having been obtained by chance was one in 10<sup>10</sup>, a degree of probability excelled or equalled by very few clinical trials indeed. In connexion with the value of certain members of the B complex for the human, there appears to be a slight inconsistency between the editorial advice<sup>7</sup> to take "supplements . . . of yeast or wheat-germ preparations . . . rather than preparations of isolated vitamins" (on the grounds that it is implied by M. Richards's work<sup>8</sup> that "ingestion of large amounts of one member of the B group . . . may induce signs of deficiency of . . . other members") and Dr. Harris's relegation of pyridoxin to this third (i.e., least significant) group, since Richards's work was concerned particularly with pyridoxin deficiency. Subject to a further

point to which I refer below, one cannot but agree with the editorial recommendation, but it is a fact that Richards's work was concerned with induced pyridoxin lack. If we accept the transference to man of the implications of Richards's work as in your leading article, we can no longer logically regard pyridoxin as of doubtful physiological significance in nutrition.

My reservation in connexion with your editorial advice relates to the recommendation of "yeast . . . preparations," and is twofold. First, the comparatively large amount of yeast which a patient must consume is not generally appreciated. While there are, of course, some highly potent strains, at least an ounce of a normal yeast must be eaten to provide even a prophylactic dose of vitamin B<sub>1</sub>. Having regard to the flavour of yeast, this is rarely practicable—least of all, as a rule, for those whose need is greatest. Secondly, it is essential that every precaution should be taken by the maker or the user to destroy all viable cells in the yeast. It has been shown repeatedly<sup>9-14</sup> that yeasts cannot all be relied upon as sources of vitamin B<sub>1</sub>, and that yeasts may be used in the human as negative sources of the vitamin. Indeed certain yeasts are actually recommended by Kingsley and Parsons<sup>15</sup> as offering a convenient and rapid means of depleting human subjects of B<sub>1</sub> without the need of using unpalatable "deficient" diets. This fact has been widely overlooked, and both in this country and in the U.S.A. the "liveness" of certain yeasts has actually been adduced as a recommendation for their use.

In conclusion I should like to refer to two questions of dosage or standard requirements. It is now becoming clear (and Dr. Harris, in citing the L. of N. standard for vitamin A—3,000 i.u. as carotene, equivalent to 1,000 to 1,500 i.u. as preformed "animal" A—gives tacit approval to this viewpoint) that the human requirement is nowhere near the figure of 4,000 i.u. included in such prophylactic preparations as vitamin A and D capsules, N.W.F., still less the 4,500 i.u. included in "pluravit," N.W.F.

It does appear, therefore, that in the present state of world shortage of vitamin A more general acceptance of the lower figures—fairly conclusively established since the L. of N. standards were evolved, by the Accessory Food Factors Committee of the M.R.C.<sup>16</sup>—could result both in substantial financial economies in this country without the slightest risk of prejudice to health and, what is much more important, in the freeing of material for those in need who cannot at present be supplied.

My other point is in the reverse direction. Dr. Harris suggests (and few nutritionists would disagree) a daily prophylactic requirement of 1–2 mg. riboflavin. Why, then, does the formula for pluravit, N.W.F., provide only 0.05 mg.?<sup>17</sup>—a quantity which is so inadequate in relation to needs that a food manufacturer claiming riboflavin activity on the label of a foodstuff providing in normal daily usage even as much as four times the pluravit-content figure would still contravene the Ministry of Food's directive relating to the administration of the Labelling of Foods Order, and would also render himself liable to prosecution under the relevant Defence Regulation for misleading the purchaser.

These various points relating to requirements of vitamin A, therapeutic usefulness of para-aminobenzoic acid and vitamin E, precautions in the choice of yeast preparations, and the token riboflavin content of pluravit are all worthy of note by those prescribing vitamin preparations.—I am, etc.,

#### Vitamin-C Content of Fruit-squash Concentrates

SIR.—Your question and answer on this subject in "Any Questions?" (Aug. 23, p. 318) has come to our notice. In our view both the question and the answer are couched in terms which may give rise to some misconception regarding the true position. It is an accepted fact that fruit squashes made from citrus fruits retain no appreciable quantities of ascorbic acid,

even though they do contain 25% of fruit juices, and contain (generally) sulphur dioxide, which acts as a preservative of vitamin C.

Fruit squashes are almost entirely produced from juices imported into this country in concentrated or unconcentrated forms, and the retention of ascorbic acid is extremely variable. It is a fact that as yet no claims are being made for vitamin-C contents in any squashes, and the relationship suggested in your answer—i.e., that the fruit-squash concentrate should contain one-quarter of the ascorbic acid in the fresh juice—cannot be upheld.

The use of the term "concentrates" in connexion with these squashes is open to objection. Under the existing S.D.I. regulations fruit squashes are placed in the category of "concentrated beverages," but this term possesses no significance to the general public. On the other hand we have the Ministry of Food welfare orange juice, which is in fact a concentrated juice, and national rose-hip syrup, which is similarly a product which has been concentrated from the raw juice or extract. In this case the concentrated product contains many times more vitamin C than the fresh juice. In a further category we have black-currant syrup and purée, which contain less ascorbic acid than the straight juice or pulp, but in which the vitamin C is remarkably stable.

As a means of comparing these figures the following table may be of use :

Substance	Ascorbic Acid in 1 oz. (28.4 ml.)
Ministry of Food welfare orange juice .. .. .	57 mg.
National rose-hip syrup .. .. .	57 mg.
Black-currant syrup .. .. .	20 mg.
Black-currant purée .. .. .	20 mg.

It is probably wise to regard only those products whose labels indicate a definite guaranteed ascorbic-acid content as having any appreciable vitamin-C potency.—I am, etc.,

Bristol.

VERNON L. S. CHARLEY.

### Penicillin for Infected Hands

SIR.—The article by Mr. Frank d'Abreu, Surgeon Lieutenant Charles M. Flood, and Dr. Harold B. Hewitt on penicillin for the treatment of infected hands (Oct. 18, p. 603) should be publicized widely if only to cut the rate of absenteeism in these critical days. The letter by Dr. John P. Raw (Nov. 1, p. 707) on the local application of penicillin should also be noted for economical and very valuable method. It was one that I deduced to the 84th General Hospital in October, 1944, using 0.000-unit tablet of calcium penicillin because of its slower rate of absorption.

My method was to introduce 1 or 2 tablets into the abscess cavity and occlude the wound wherever it was possible with elastic adhesive bandage, leaving it unattended for 24–48 hours. A second application of the tablets was sometimes necessary. Even after the first dressing it was remarkable to note the diminution in inflammation and induration around the lesion. The method was very valuable in the case of carbuncles and solitary boils. Quite often the central slough in a carbuncle would come away with removal of the first dressing.

I agree with Dr. Raw that the surrounding inflammation and induration seem to form a barrier to blood-borne penicillin and that the local application is much more effective.

Since my return to civilian practice I have continued to use this method and have only found it necessary to use parenteral penicillin in those cases where the abscess, boil, or carbuncle is in its very early stages—that is, before the barrier effect is set up.—I am, etc.,

London, E.4

H. WINCH.

SIR.—I read with much interest the method of local penicillin treatment as described by Dr. John P. Raw (Nov. 1, p. 707). I have used this method extensively for the past three years with outstanding results. I first treated cases of R.N. personnel with the 10,000-unit tablets as issued to the Services. Hand and foot infections were successfully treated with a minimum of incision. The treatment of tendon-sheath infection was very satisfactory. In most cases pus formation had ceased in 72 hours and healing and function were complete in about 16 days.

The most outstanding case, however, was that of a farmer with a deep palmar infection. The hand had the colour and contour of a boxing glove, with severe lymphangitis and oedema extending to the axilla. Four 10,000-unit tablets were inserted deep in the slough situated in the centre of the palm, and a small gauze dressing covered with G.P. tissue was applied. Within 12 hours serum and lymph were pouring from the slough area, and the slough came away the following day. The contours of the hand and arm were restored in 24 hours. In 72 hours active movements of the fingers were encouraged. With difficulty I restrained him from resuming full duty on the seventh day.

To facilitate the introduction of the tablet I thrust a grooved director deep into the septic area, place the tablet on edge in the groove, and push it on with a probe. The point of the director is depressed and the tablet runs over the end and remains. The director and probe are then withdrawn. The method is very useful in the treatment of breast abscess, and the size of the incision can be greatly reduced. In some cases of breast abscess I have combined local treatment as described with twice-daily doses of 300,000 units. I am not yet satisfied that the results are an improvement on the local method alone.—I am, etc.,

Alexandria, Dumbartonshire.

WILLIAM SCOTT.

### Road Accidents

SIR.—Dr. E. Granger (Nov. 1, p. 709) appears perhaps to confuse the activities of the tongue and of the mind. High output of the one is not always accepted as evidence of good functioning of the other, and the mind of the silent driver may be better occupied than by trivial conversation. Does Dr. Granger feel less safe when in public-service vehicles than when driven by his garrulous acquaintances, and would he advocate, for safety reasons, that the drivers of buses and coaches should sit with the passengers, in order to enjoy the benefit of distracting conversation?

The apparent attempt to discredit the saying, "Don't speak to the man at the wheel," which of course goes back long before motor-car days, is a poor contribution to make to road safety. If, as your leading article suggested, medical men in general are seriously perturbed about road accidents, they may be interested to know that they can make some positive contribution by joining, for a very modest subscription, an association which neither supports nor is supported by any sectional interest, but which exists solely for the quite praiseworthy motive of the promotion of safety and the preservation of life on the roads.—I am, etc.,

London, N.W.8.

R. J. CLAUSEN.

### B.C.G. Vaccination under the Red Cross

SIR.—With more than half a year's experience of B.C.G. vaccination in several European countries the Danish Red Cross is now in a position to give a fairly detailed account of its work in this field. Starting with Poland it has extended its work to Yugoslavia, Hungary, Austria, and the American and British zones in Germany. The sum allotted to this work is 3.5 million Danish crowns, and it is actively supported by the Danish Government and the State Serum Institute, whose chief, Dr. Ørskov, has published a commendatory article on B.C.G. vaccination in the September number of the *Journal of the Danish Red Cross*.

The work has hitherto been carried out by 15 teams, each composed of one doctor and two nurses, but the ultimate target is 60 such teams. Denmark cannot alone supply as many as 60 doctors trained in B.C.G. work, and such experts are therefore being recruited in Norway and by sending doctors from various other European countries to Denmark, where they are initiated into the technicalities of this work. In principle everyone from the age of 0 to 80 is eligible for B.C.G. vaccination provided he or she is tuberculin negative, but as—in Poland, at any rate—practically everyone over the age of 25 is tuberculin-positive it is under this age that this work is confined in practice. This vaccination costs only about sixpence per head.

In order to provide an adequate supply of fresh vaccine the Danish Red Cross has purchased three aeroplanes to carry it to different parts of Europe. In Yugoslavia the Danes have handed over their work to the Yugoslav Government after

working in this country for nine months. In the *Journal of the Danish Red Cross* for October Dr. Henningsen points out that in the past half-year the Danish Red Cross has examined about half a million persons, each of whom was dealt with three times. Tuberculin-testing is so well organized that 1,000 persons can be tested by the same nurse on the same day. Between 1,500 and 2,000 persons have been examined every day by each team, and in a recent interview in *Morgenbladet* for Oct. 28 the President of the Danish Red Cross, Kai Hammerich, refers hopefully to the prospect of vaccinating a million persons every month.

So we see that after twenty years of research and mass experiment the Danes have not only made out a very convincing case for B.C.G. vaccination but have also made it an article for export. What of the attitude of my fellow countrymen in England to B.C.G.? Masterly inactivity verging on the sublime? Or on the dodgery?—I am, etc.,

Sunnfjord, Norway.

CLAUDE LILLINGSTON.

### Intravenous Procaine

SIR.—Dr. Peter Parry (Oct. 25, p. 669) refers to intravenous injections of procaine, saying that "the recommended dose of 10 ml. of 1% solution can be much exceeded with apparently complete safety." It should be realized that it is not the total dose which matters but the rate of injection. Procaine is rapidly broken down in the blood stream by the enzyme procaine esterase into diethyl-amino-ethanol and *p*-aminobenzoic acid. If the rate of injection is greater than the rate of hydrolysis, the concentration of procaine in the blood stream will rise and cause toxic symptoms in the following order: tachycardia, muscular twitching, convulsions, respiratory failure, death.

In the average fit adult tachycardia usually appears if the rate of injection exceeds 20 mg. per minute, and as a general rule this should not be exceeded. If an overdose has inadvertently been given, the intravenous injection of a short-acting barbiturate such as soluble thiopentone is the best treatment. The barbiturates not only act as anticonvulsants but appear to have a true antagonistic action to the analgesics containing the *p*-aminobenzoic-acid grouping.—I am, etc.,

St. Albans, Herts.

C. LANGTON HEWER.

### Peptic Ulceration

SIR.—The annotation (Oct. 18, p. 621) on the findings of Gibbs perpetuates two widespread fallacies to which grave exception must be taken. (1) Radiographic "evidence" of healing. Nothing is more illustrative of the divorce of radiography, indeed of clinical medicine, from morbid anatomy than the belief that if x-ray evidence of ulcer disappears the ulcer is healed. In the case of gastric ulceration, endoscopy will show unhealed ulceration six or twelve months after x-ray signs have disappeared. Morbid anatomists of the living—surgeons—confirm this also in the case of the duodenum. The pertinent question is raised, "What is the basis (a) of the x-ray appearances of ulceration and (b) of the symptoms?" The classic symptom-free intermissions with a persistently unhealed ulcer are interrupted by periods of "activity." In what does this consist? Extension of the ulcer? No, a symptom-free ulcer of the stomach may slowly extend to an enormous size. The answer is simple: both symptoms and almost entirely the x-ray signs are produced by periodic flares of circum-ulcerous cellulitis.

The genesis of pain by the resultant interference with the musculature and gastric tension surely has been adequately established by numerous clinical workers such as Hurst, Ryle, Douthwaite, and others, though the idea of hyperchlorhydria burning the sore in the stomach seems ineradicably widespread still. The gastroscope establishes beyond doubt the source of occult blood as the swollen inflamed mucosa around the ulcer, though the common belief is an origin in bleeding granulations not shown endoscopically. Indeed the only symptoms arising from the ulcer itself are massive haemorrhage from erosion of large arteries and acute peritonitis from perforation. The oedema of mucosa and musculature together with muscular contracture exaggerate enormously the x-ray crater. Careful examination of the lesser-curve outline shows that the exere-

science is in reality largely an appearance produced by a filling defect due to oedematous mucosa. With the subsidence of the oedema symptoms rapidly disappear; next the occult blood ceases; finally the x-ray crater, with all attendant rigidity spasm, etc.

The gastroscope, however, tells a most disillusioning tale. Healing of the flat area of epithelial deficiency, now symptomless and signless, may take a further six, nine, or more months before safe epithelialization is attained, even with the most stringent and irksome medical treatment. These facts are readily proved in cases of gastric ulceration; there is no reason for doubting that they apply equally to the duodenum. All, therefore, that can be claimed for radiography is the demonstration of increase or recession of circum-ulcerous inflammation. The definition of "activity" of an ulcer might be stretched to include this most characteristic phase of the condition, but the claim to demonstrate "healing" must be emphatically rejected.

(2) The other objection one must raise is in a large part conceded by your review—that the test-meal by any technique gives anything resembling a realistic demonstration of gastric secretion. How indeed can it when it concerns itself solely with hydrochloric acid? It may be that this secretion is to some extent parallel with that of the enzyme, but it is a very unsafe assumption. The reverse of this assumption leads to one of the pathetic illusions of medicine (like the instantaneous sterilization of the skin by a dab of antiseptic before a hypodermic injection). The patient has achlorhydria: all that is necessary to restore gastric function is to administer a few minims of dilute hydrochloric acid at intervals throughout the day. Pepsinogen *here*, it is presumed, is secreted normally. Admittedly more difficult and tedious, the estimation of peptic activity of gastric secretion is surely the truly relevant factor, for which one will search in vain for attention in the consideration of peptic ulceration; instead of which general attention is universally directed to neutralizing an acid which one presumes eats holes in the stomach and duodenum. The statement is made that concentration of HCl above 0.08% produces no increase in peptic activity. What then becomes of the simple faith in hyperchlorhydria? Until attention is turned from acid-and-alkali-test-tube theory and practice in peptic ulceration to some real indication of secretion it is not to be hoped that much advance can be made in either.—I am, etc.,

London, W.1.

C. JENNINGS MARSHALL.

### Education for General Practice

SIR.—Dr. James M. Taylor (Nov. 1, p. 706) makes a plea for the medical student to be employed as a nursing orderly at the same time as he is engaged in dissecting the cadaver. It is as well to recollect that the appalling mortality from puerperal sepsis persisted unabated in the lying-in wards of the Vienna hospitals until Semmelweis put a stop to this route of cross-infection. Until the student has thoroughly appreciated in his surgical training the need for rigid asepsis, he is safer out of the surgical wards. In any event the study of anatomy is a full-time task and will not be made less burdensome by devoting precious time to sweeping floors and emptying bedpans.—I am, etc.,

Southsea, Hants.

J. A. SEYMOUR-JONES.

### The G.M.C. and Medical Education

SIR.—Dr. C. E. S. Flemming (Oct. 25, p. 669) says my letter on radical revision of the curriculum "lands us in a quandary." Patients whose rectal cancers are examined too late in the disease are in a much worse one. Such are common under the present education. My gravamen is that the student of medical science is *not* taught "those things that he *will want to know*," and that the art of medicine, which is half of general practice, needs unfolding in the impressionable years in hospital. The letter of Dr. James Taylor (Nov. 1, p. 706) gives cogent support to my plea for educational reform, and offers an admirable practical suggestion. A panel of G.P. tutors would, he claims, be mutually beneficial to student and teacher. It would counteract the degradation of the family doctor which he so poignantly describes.

Dr. Flemming asks whether the young doctor would find effective help at a health centre. No, the name is a misnomer

for a fortuitous collection of doctors having no intentional physiological bond. It will reduce, not raise, the prospects of the average patient. If a doctor is any good, his patients want him, having chosen him and put their faith in him. If patients cannot do this last, then half his healing power vanishes. When a doctor takes a pride in his practice he will not welcome patients being banded about from one to another. Undivided loyalty is part of the good doctor-patient relationship.

The student needs a practical training to cope with common disease and to lead his flock in the cult of health. The complexity of modern medicine points to a partnership for the average young doctor and urban practice. This includes the incentive of owning the practice, and some degree of competition helps to "ginger up" effort. Conditions of pay, etc., must encourage *quality*, not mere *quantity*, of work.—I am, etc.,

Bristol

A. WILFRID ADAMS.

### Belladonna Poisoning

SIR,—In their article (Oct. 18, p. 611) on this subject Flight Lieutenants M. Hamilton and A. B. Sclare quote Glaister (1944) as stating that cases of accidental poisoning by belladonna preparations are comparatively rare. A brief record of four cases that have come to my notice may therefore be of interest.

#### CASE REPORTS

A woman aged 30, soon after taking her usual drink of herb tea, became strange in manner, rambling and talking to herself, and fumbling aimlessly with the buttons of her clothes. She was found to be suffering from belladonna poisoning, the deadly nightshade having evidently been accidentally included among the herbs. Although there was no alarm as regards this patient's life, she was badly shaken for a week or two and never quite regained her previous health.

A man aged 62 was in the habit of treating attacks of gout affecting his great toe by rubbing in the liniment of belladonna. One day he rubbed in linimentum A.B.C. (alcohol, belladonna, and chloroform) in addition. This apparently increased the absorption, as on the following morning he had the typical low muttering of belladonna poisoning. He had no recurrence and no ill effects.

A man was about to have a lipoma removed by a relatively inexperienced operator. I looked in to supervise just after the injection had been given, and found the patient a trifle fidgety and muttering to himself. The pupil was seen to be dilated. The solution that had been injected was inspected, and it was found that by mistake an eye lotion containing atropine had been used. Within a few hours this man had a temperature of 106° F. (41.1° C.). He made a rapid recovery.

A consulting physician informed me that he had been called in a case of pneumonia as the patient had become delirious. The type of delirium suggested belladonna poisoning, and he found that the medicine which was being given contained belladonna. This was stopped and the patient recovered.

These cases all occurred during the six years 1911 to 1917, and I have not seen a case since then. The symptoms are so characteristic that the condition can be recognized at a glance; they are clearly described in Hamilton and Sclare's article.—I am, etc.,

Bradford

PETER MCEWAN.

SIR,—When I was R.M.O. at what is now called the Princess Beatrice Hospital two boys about 15 came into casualty. One was continuously talking quite incoherently; the other knew nothing of the patient but was doing the good Samaritan by taking him to hospital. The patient's pupils were noticed to be extremely dilated. He was treated for belladonna poisoning and quickly recovered. It turned out that he was a chemist's boy whose job it was to wash bottles, and he tasted some sticky black stuff that looked like liquorice and tasted sweet (? belladonna and glycerine).

During the last war when M.O. of a tube shelter I was called to an old lady who was talking incoherently, and it was suggested that drink might be the cause. Thinking of a possible central nervous disturbance I looked at the pupils, which were much dilated but equal. I thought of belladonna poisoning, and her pockets were searched for medicines or tablets. Eventually she was found wearing belladonna plasters on ulcerated varicose veins.

It might seem to be advisable to tighten up the regulations for the sale and dispensing of belladonna. Our friends the

Russians have set us an example in this direction. In Archangel in 1916 one of our party had lumbago and we thought of an application of belladonna. A fellow M.O. and I hunted the chemists' shops exhibiting our passports, red crosses, etc., but to no avail. Regulations were regulations, and only a Russian doctor's prescription would be recognized. The last chemist we went to was a friendly soul who asked us whether we really wanted belladonna, and we replied in the affirmative. He advised us to go to the beauty and cosmetic shop round the corner, where, he said, we could get a pound without any permit at all. We took his advice and carried off the goods.—I am, etc.,

London, N.1.

LINA M. POTTER.

### Genetics and Science in the U.S.S.R.

SIR,—The leading article on the Lysenko controversy (Oct. 18, p. 616) contradicts itself to its own destruction as follows. In the fifth column of the article Darlington is commended for putting on record the "facts" of the liquidation of certain Soviet biologists and scientists since 1928, when "Marxist orthodoxy began its ideological incursions into the domain of science," Lysenko being the "new genetic prophet." At the bottom of the third column the article states that "the Lysenko school has many opponents" (meaning Soviet opponents). Therefore either the liquidation was ludicrously inefficient, or else it never happened. Further, how can one have both a "iron curtain" and also the detailed knowledge of Soviet affairs claimed by such as Darlington? These aspects of the and similar matters are irreconcilable.

The whole matter has recently been discussed in three articles in *Modern Quarterly* of Autumn, 1947, in which reference is made to an earlier article of Darlington's in *Discovery*, 1947. He is quoted as saying: "These are no longer questions which can be argued about in Russia. All those who have been prepared to argue have been put away." Yet "the Lysenko school has many opponents"!

I conclude that the *B.M.J.* article is simply another set-piece of anti-Soviet pyrotechnics. Fireworks make much noise, but have little effect on any structure of solidity. And one looks foolish (at best) in praising Hudson and Richens for being "clear, temperate, and impartial" and then falling so obviously short of that standard oneself.—I am, etc.,

London, N.W.11.

R. R. WILSON.

SIR,—In the issue of Aug. 30 (p. 339) the editorial policy of the *British Medical Journal* was stated to be governed by "a sincere desire to inform British readers of the advances and contributions of Russian medicine." As one who deplores the scarcity of news of these matters in the British Press, I heartily welcome this declaration, and it was with keen anticipation that I hastened to read in the *Journal* of Oct. 18 (p. 616) your leading article devoted to the important genetics controversy in the U.S.S.R.

I found, however, that the article omitted to mention the continued official recognition and encouragement of orthodox Mendelian genetics in the Soviet Union. Furthermore, it was rounded off by an acclamation, as a great service to truth, of the wild charges of Darlington published in such a periodical as the *Nineteenth Century*. Thereby, in my view, the editorial deserted the field of objective scientific criticism and entered that of political aggression against an allied nation. It may be helpful to those who wish to study this important subject objectively to mention the valuable series of articles contained in the current issue of *Modern Quarterly*. In one of these there is stressed, with evident pertinence, the importance of reading the original work of Hudson and Richens.—I am, etc.,

Crossnac, Glam.

J. B. ATENS.

SIR,—The core of the article "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616) is a quotation of the assertion by C. D. Darlington that Vavilov and others were imprisoned and murdered because of their scientific views. Hudson and Richens in their monograph, which is mentioned in the article as "clear, temperate, and impartial," could find no evidence that this was so, and surely the only verdict that a reasonable man can pronounce at the present time is one of "not proven."

The weaknesses of Lysenko's *New Genetics* and the inadequacy of the scanty experimental results on which it is based cannot be disputed. It is understandable, however, that the prestige of such a man, whose earlier work was so brilliant and achieved substantial practical success, should be great, and that he should have a considerable following among lesser biologists and agriculturists. We have had a somewhat parallel case in this country in MacBride, who held equally heterodox genetical views based on equally unsound experimental data, but who retained his chair and published books on the subject until his death. The non-scientific taunts that have been hurled by each side can also be paralleled in previous scientific controversies in other countries. Until Darlington produces his "sufficient documentary authority," or further evidence is forthcoming from other sources regarding the death of Vavilov, the only scientific attitude one can adopt is an open mind on the matter.—I am, etc.,

Orpington, Kent.

F. H. BRIGHTMAN.

SIR.—There are a number of controversial statements in the leading article (Oct. 18, p. 616) on the above subject. I would like to refer to one general question, but I hope that the other points will be taken up by the experts in the different fields concerned. The statement which I would question is the one in which you attribute a comparatively recent growth to an alleged state of philosophic calm on the part of scientific investigators. Surely it was only in times before the introduction of the scientific method that the investigator was able to isolate himself in an atmosphere of "philosophic calm." Such a calm could only be derived from seclusion from the outside world and could only result in the elaboration of an idealist philosophy and dogmatic teaching. As a result of their energetic turning back to reality and their iconoclastic attitude to dogma, revolutionaries such as Newton and Darwin were able to dispel the philosophic calm of the armchair "investigator." From then on, to borrow your own phrase, idealism could only be preserved for scientific workers by an "alogical" process—a divorce between religious views on the one hand and the practical results of their own investigations on the other.

It was by an application of the scientific method to political economy, similar to that which Newton and Darwin had achieved in physics and biology, that Marx and Engels were able to dispel the philosophic calm of the pre-Marxist economists. The essence of their teaching was a refusal to recognize the immutability of the present structure of human society, just as Darwin refused to recognize that the world had been created precisely as he found it in the 19th century. Dialectical materialism has often been dismissed by those who do not understand it, or who find it inconvenient, as a "new religion." There is no doubt that the introduction of the use of meteorology in the countries of the Middle East and India to regulate crop sowings in lieu of reference to the priest is regarded by some as the substitution of one religion for another, since to the uninitiated it is just another mystery. I do not think, however, that this should be regarded as a valid reason for classifying meteorology with alchemy and Zoroastrianism rather than with geology and botany.

You state that doubtless a Communist (among others) tacitly accepts some form of realist or material philosophy. Surely, however, it is evident that, whereas this acceptance may be tacit in the case of a professed idealist—e.g., Oliver Lodge—in the case of a Communist scientist—e.g., J. B. S. Haldane or Joliot Curie—this acceptance is by no means tacit. On the contrary, it is clearly and explicitly expressed by the mere fact that the scientist in question professes himself a Communist and thus declares publicly that he has accepted a materialist outlook.

The recent discoveries in atomic physics and spheres of dynamic biology such as genetics have made the mechanical materialism of the scientists of the last century appear inadequate. This has resulted in a turning back towards idealism, as evidenced by the popularity of neo-mystical writers such as Jung. For those, however, who wish to continue to rely on the experimental and scientific method rather than to seek to explain the natural phenomena of psychology and sociology by some hypothetical "Einsicht," dialectical materialism offers a satisfactory method of arranging the facts resulting from

experimental work, a method which, by seeking to expose the contradictory forces operating in a natural process, reveals its dynamic nature. Thus the attention of the dialectical materialist is focused, not upon the ideological conflict between the protagonists of "nature" and "nurture," but upon the organism itself as the seat of the interaction of these material forces.

It is one of the essentials of dialectical materialism as stated by Marx, Lenin, or any other of its main exponents that no theory can be wholly adequate to its purpose and that it will need revision or perhaps complete replacement as new facts are discovered. This applies equally to the theories which Lysenko uses to explain his results and for which no permanent validity can be claimed. The best method of assessing the work of such scientists is, surely, not to accuse them without adducing any material evidence of liquidating their opponents, but rather to point to the successes which have been achieved by the use of their methods in acclimatizing useful plants to the wastes of the Arctic or of the Kara Kum and in evolving new strains of domestic plants which will help to banish for ever the spectre of famine which has haunted mankind for so long.—I am, etc.,

St. Mary Cray, Kent.

BRIAN H. KIRMAN.

### The Extent of Neurosis

SIR.—Was there really so little neurosis in the Victorian age as Dr. H. Crichton-Miller (Oct. 25, p. 669) tells us? And has fear, economic and social, really been gradually "eliminated"? and also the response of effort to the fear motive? If developments, as visualized by Dr. Crichton-Miller, should have reduced the extent of neurosis, why have they not?

The replacement of individual anxiety by passive solidarity with the group, and of individual effort by "talk of strikes," could not have led to increased anxiety and conflict unless the individual would subconsciously recognize that his striving for collective security through constitutional channels is either wicked or unwise. Do the working people really suffer from this conflict?—I am, etc.,

London, N.W.11.

B. SAALER.

### Treatment of Varicose Veins

SIR.—I have read with much interest the article by Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) on the passage of sclerosing fluid through communicating veins of the thigh and leg when injections are made into varicose veins. But I do not think that sclerosis of a deep vein ever occurs in consequence, and it has not occurred in over 20,000 injections that I myself have given. Oedema of the lower leg may occur, but this is due to lymphatic block caused by periphlebitis. Even this will not occur if the leg is firmly strapped up with "flexoplast," which has been my invariable practice for many years now after injecting all but the very smallest leg veins. In fact I consider that it is an essential part of the treatment.

The two main communicating veins are at the junction of the middle and lower thirds of the thigh and at the junction of the middle and lower thirds of the leg for the internal saphenous vein. Of these, the latter is the more important and the more difficult to sclerose. It is usually below this that ulcers and other complications usually occur. If I find it patent after the injection of the main trunk, I inject it directly with 2 ml. quinine and urethane with the leg in a horizontal position, and after pressing on the vein for some minutes I apply strapping to the whole leg. This is usually sufficient to sclerose the communicating vein and the trunk below it, but on occasions I have had to resort to a "twin" injection of "lithocaine," 5 ml., and quinine and urethane, 3 ml., and even this massive and powerful injection has failed to produce any sclerosis in the deep veins, though the local result has been excellent. A running stream will not freeze as readily as the stagnant ditch near it, and it is probable that the increased flow in the deep vein quickly dilutes the sclerosing fluid and renders it innocuous.

I agree with much that Mr. Harold Dodd (Nov. 1, p. 708) writes, especially when he stresses the importance of varicose veins. But I fail to understand his objection to clinics. We who work in them probably see ten times as many cases of varicose veins and their complications as come to a hospital surgeon's out-patient clinic. I once had to deal with 104 in one afternoon, and I rarely see fewer than 40. A considerable amount of experience is thus built up.

I find that injection treatment properly performed will give as good results as ligation with injection and better than ligation alone. Many of the cases that come to me have scars of operations—in

one case five—and are in a worse condition than they were before their operations. Moreover, operation is not without its danger to life and limb, and many fatal results have been reported. In seventeen years that I have been doing injections I have had no fatality nor lost a limb. Injection therapy is so simple and safe that scarifying the intima, as described by Mr Riddock, seems to be unnecessary and even barbarous, though it may give excellent results when performed by his skilled hands. Nor is it necessary to pass a long catheter down a vein to enable a sclerosing fluid to reach its furthest point. If the injection is made into the highest part of the vein, simple massage will drive a wave of fluid down the main trunk, its branches, and also into the communicating veins. In this way the complete internal saphenous system can be soundly and lastingly sclerosed from the groin to the ankle.

But I will admit that in a small minority of cases injections seem to have little or no effect. These unfortunate people must submit to operation or wear stockings for the rest of their lives.—I am, etc.,

London, S.W.7,

R. SIMPSON HARVEY.

### Balantidiasis

SIR,—I have read with considerable interest Dr. M. Shun-Shin's article on "Balantidial Dysentery in Rodriguez and its Treatment with Mercury Biniode" (Sept. 13, p. 417). I should like to associate myself with the suggestion of Dr. Shun-Shin, and the following case report would not be out of place.

A Hindu male aged 40 consulted me on Oct. 9, 1947, for an attack of intractable diarrhoea of three months' duration, the number of motions being 20-30 per day. Stool examination revealed *Balantidium coli* and giardia cysts. He was put on emetine injections 1 gr. (65 mg.) daily, methylene blue 2 gr. (0.13 g.) in capsules twice a day, and mepacrine tablets, one tablet thrice daily for five days. With this treatment, though the giardia cysts disappeared, the balantidia continued to be present in highly motile forms. Then on the suggestion of Dr. Shun-Shin I gave an intramuscular injection of 1/6 gr. (11 mg.) of biniode of mercury, and stool examination four days later revealed complete absence of the ciliates. In spite of negative stool findings another injection was repeated, and two subsequent stool examinations on different dates failed to show the balantidia. The patient at the time of reporting had been passing 2-3 normal motions per day and was feeling very well.

The application of hydrarg. biniode in the treatment of balantidiasis has opened up new prospects of cure and eradication of an otherwise very intractable and persistent infection, and further reports in support from members of the profession would be welcome.—I am, etc.,

Saahpur, West Bengal.

S. PRAMANIK.

### Anticoagulants in Coronary Thrombosis

SIR,—The annotation on dicoumarol (Oct. 25, p. 662) and John T. MacLachlan's letter on heparin for coronary thrombosis (Nov. 1, p. 709) will, I fear, raise hopes which are doomed to bitter disillusionment. I have nothing but praise for the action of dicoumarol in peripheral phlebotrombosis and thrombophlebitis. Not one of my cases has developed an embolism, and I have a strong impression that the local manifestations subside more rapidly. Although there has been an alarming drop in the prothrombin index in one or two cases, there have been no untoward results.

With this experience of dicoumarol it was with high hopes that I commenced to use it in cases of coronary thrombosis a few months ago. The first two cases in which I used it had each had more than one lung infarct before treatment was started, and each had phlebotrombosis in one leg. Despite a satisfactory drop in the prothrombin index both patients developed further lung infarcts. One occurred when the index was 54%, the second while the index was rising over a period of three days from 43% to 74%. In each case the illness ran a particularly stormy course, and occasioned greater anxiety than the average patient with coronary thrombosis and lung infarction. In addition to these two cases two patients with hypertensive heart failure and lung infarct were given dicoumarol. One of them had two further infarcts during the treatment, the first on the day when his prothrombin index stood at 76%, the other with a prothrombin index of 43%. The second patient had an extension of thrombophlebitis during an intermission in her treatment, and had another lung infarct after the treatment was resumed.

The fifth patient to receive this drug completed my discomfiture and disillusionment. A woman aged 57 who suffered from hypertension with angina of effort was admitted to the ward for thiocyanate treatment. On the fourth day, when her blood pressure had fallen

from 220/110 to 180/94, she developed a severe attack of coronary thrombosis. Within half an hour of the onset of her pain she had profuse haemoptysis, attributed at the time to pulmonary infarct though necropsy subsequently showed that it was due to pulmonary congestion. Thiocyanate was immediately discontinued and dicoumarol was started two days later. On the eighth day after her attack (sixth day of dicoumarol treatment) she seemed to be progressing satisfactorily, and her prothrombin index stood at 38% when she suddenly had another attack of coronary thrombosis and died after a few hours. Necropsy showed the original thromb in a coronary artery with widespread recent extension, which according to the pathologist, had taken place a few hours before death.

This last case makes it clear that the blood coagulability is not the only factor which influences extension of a coronary thrombosis, perhaps not even the most important factor. Figures which I hope to publish in due course, from a series of 242 cases, indicate that the mortality from all causes within the first three months is closely related to the degree of shock accompanying the attack itself. In 154 cases there was no shock, though pain in many was severe; the mortality in the first month was nil and in the first three months was only 2.4%. In 88 cases with shock the mortality was 27% in the first month (29% at ages below 50, 19% at age 50 to 59, and 48% at ages over 60).

It would seem, therefore, that the most hopeful line of attack lies in the early and effective treatment of the initial shock. I am experimenting along these lines, making use of a slow intravenous glucose-saline drip to which an ampoule of "cardophyllin" (0.48 g.) is added by injection into the rubber tubing. Treatment has so far been confined to seriously shocked patients, and they have been given morphine when required for pain. While it is too early as yet to make any claims, the results so far are highly encouraging. There have been two dramatic recoveries in patients whom I regarded as moribund, and a third striking recovery in one whom I thought seriously ill though not hopeless. One of these three patients later developed an embolism at bifurcation of abdominal aorta.—I am, etc.,

Glasgow.

ALBERT A. FITZGERALD PEEL.

### Knee-jerk Examination

SIR,—I have been using a simple method of eliciting the knee jerk during the last few years. Recently other colleagues to whom I have demonstrated it have shown interest. Their interest has prompted me to describe it. In this method no percussion hammer is required.

The middle finger of the left hand is placed carefully over the patella tendon, and then the middle finger of the opposite hand is brought sharply down on to the dorsum of the left middle finger as in percussion elsewhere. A positive response is felt by a tightening of the tendon under the examining finger.—I am, etc.,

London, W.5.

J. J. SHIPMAN.

### Yeast Extracts and Fat Absorption in Sprue

SIR,—I was interested to see the conclusions of Drs. D. A. K. Black and L. P. R. Fourman (Oct. 25, p. 645) regarding the effect of yeast extracts on fat absorption in sprue. Cases such as they referred to were in the Sprue Research Unit at Poona, where their fat balances and treatment were carried out under my direction. The biochemical estimations were performed by Drs. Black and Fourman as described by them. In a group of cases treated by yeast extract, examined statistically by Mr. Dilwater, the period of treatment was shown to coincide with improvement in fat absorption. These cases had been previously treated by parenteral liver extract in large doses, parenteral nicotinic acid, and riboflavin shortly before yeast extract was used. In my view this finding showed that the whole pattern of therapy may have decreased fat excretion, not the yeast extract alone, as has been concluded. For example, the possible necessity for previous or coincidental liver therapy for the reduction of fat excretion on yeast extract is not considered by them in their article.

The issue could be easily settled by the use of yeast extract alone. I would like to ask if Drs. Black and Fourman have investigated cases other than those on the Sprue Research Unit, as yeast extract alone was never used on these cases. I think it

relevant to point out that yeast extract was not used on patients in the relapse phase of the disease, and that careful clinical observation revealed no beneficial effects from it during remission.—I am, etc.,

Staines, Middlesex.

K. D. KEELE.

### Hospital Treatment of School-children in Shropshire

SIR.—I wish to bring to the notice of the profession at large a situation which has recently developed in Shropshire, which this Branch regards as one of the utmost gravity in its bearing on the everyday work of the general practitioners of the area, and the implications of which are widespread and ominous. The Education Act, 1944, imposes on local education authorities "the duty to make such arrangements for securing the provision of free medical treatment for pupils in attendance at any school or county college maintained by them as are necessary for securing that comprehensive facilities for free medical treatment are available to them."

The Education Committee of the Shropshire County Council, in drawing up its scheme, has decided that all hospitals with which it proposes to enter into arrangements for the treatment of school-children shall comply with the following conditions:

"(1) There shall be on the staff of the hospital a resident medical or surgical officer, or both, according to the type of case to be dealt with.

"(2) Treatment for eye, ear, nose, and throat conditions shall only be carried out by, or under the supervision of, a specialist in the appropriate condition, who shall be of consultant status.

"(3) Surgical cases of all categories, whether requiring operative treatment or not, shall only be treated by, or under the supervision of, a Fellow of the Royal College of Surgeons of consultant status, who will himself be expected to carry out any operative treatment required unless it is of a very minor nature.

"(4) Medical cases shall only be treated by, or under the supervision of, a physician of consultant status."

It will be plain to all that the application of these conditions results in the complete elimination of the general practitioner from any part in the treatment of such children, which now may only be carried out in such hospitals as have an active staff of consultant status. In Shropshire this has resulted in a remarkable state of affairs. The county is a large one, covering an area of 1,346 square miles, and having a population of 262,000. Within its borders there is only one hospital available for general medical and surgical cases which fulfils the conditions laid down. It contains 280 beds, is already hard pressed for accommodation, and has long lists of patients awaiting admission—nearly 500 in fact.

On the other hand Shropshire is fortunate in having no less than eleven smaller hospitals of the "cottage hospital" type, widely distributed over the county, with a total of about 250 beds, staffed by the general practitioners residing in their vicinity, and in a high state of efficiency, with consultants available when expert assistance is required. In these hospitals much excellent work of an unspectacular nature has been and is being carried out to the satisfaction of the public, the convenience of patients and their relatives, and, not least, to the relief of the major hospital.

As a result of what I can only describe as the deplorable decision of the local education authority, taken without any approach having been made even to the authorities of the main hospital, these 250 beds will no longer be available to children of school age, since the edict has gone forth that none may treat them who is not of consultant status.

I ask you, Sir, is not this an outstanding example of planning gone mad? And I believe that when the matter is raised at the Representative Meeting it will be dealt with in such a way as to convince those concerned and any others—if such there be—of a like mind that the profession will not submit to such treatment.—I am, etc.,

H. W. BANBRIDGE.

Wellington, Salop.

President, Shropshire and Mid-Wales Branch.

### Fowl Paralysis and Poliomyelitis

SIR.—I was most interested to read Dr. J. A. Goodfellow's account of his experiments on fowl paralysis (Oct. 11, p. 586). In 1937 I saw a child with poliomyelitis on an isolated farm in Herefordshire and was surprised to find a hen lying paralysed in the farmyard at the same time. There were no other cases of

infantile paralysis notified in the district and no more chicken paralysis on the farm. I removed the brain and spinal cord from the hen and sent these to the National Hospital for Diseases of the Nervous System, Queen Square, for histological examination. It was reported that no abnormality could be found.

No doubt the simultaneous occurrence of the two diseases was a pure coincidence, especially as fowl paralysis is not an uncommon disease, but it would be interesting to hear from county doctors whether such a phenomenon is often observed.—I am, etc.,

London, S.W.1.

F. L. KING-LEWIS.

### Homosexuality and "Sexual Trauma"

SIR.—Those who are concerned with the social and clinical problems of homosexuality will welcome Mr. D. Stanley-Jones's able refutation (Oct. 25, p. 671) of the theory that seduction in childhood or early adolescence is an important aetiological factor in these cases. In addition to his cogent reminder of the frequent occurrence of homosexual experiences amounting to "seduction" in the early life-history of many well-adjusted heterosexual adults it is possible to adduce further evidence in support of the view that the "traumatic" significance of sexual seduction or assault in childhood has been greatly over-emphasized. The usual tendency has been to argue *a priori* on the basis of certain subjective ethical and moral concepts that, because such assaults are deemed to be morally "wrong," therefore they cannot fail to produce disastrous effects on their victims.

(1) As A. J. Rosanoff<sup>1</sup> has stated, "such evidence as is available would seem to indicate that such seduction can only be of lasting effect, if its direction corresponds with the inherent sexual tendencies of the subject"—i.e., psychiatric investigations tend to show that any "lasting effect" is produced, not by the seduction, but by (a) constitutional and endocrine factors, (b) psychosexual immaturity resulting from disturbances in the child-parent relationship in early childhood, or (c) more probably (in the light of contemporary research into psychosomatic interrelationship) a combination of both factors.<sup>2</sup> In all true adult homosexuals who have been thoroughly investigated there has been some indication that one or both of these factors have long been present *prior* to any seduction or assault. Furthermore, psychiatric experience shows that many true homosexuals have never been subjected to seduction in childhood and, indeed, have never had any physical relationship whatsoever.

(2) Psychiatric investigations have established beyond doubt that, in very many cases of childhood "seduction," it is the so-called "victim" who is in fact the seducer, and that the sexual act with the adult may be actively sought by the child as an expression of the latter's unconscious impulses and fantasies<sup>3</sup>—i.e., that a predisposition in the child may not infrequently be the cause of the alleged seduction. K. Friedlander<sup>4</sup> states that "it is very rare for boys who do not already display homosexual tendencies to be exploited in this way. . . . More often than not, young boys will offer themselves, if not in words then by gestures, to older men."

(3) There is considerable evidence that the large majority of children and young adolescents who have been seduced or assaulted, either by adults or by other children, and whether the act be homosexual or heterosexual, show in adult life no sign whatsoever of sexual or psychological maladjustment or abnormality. Doshay<sup>5</sup> found that, among 108 unselected cases who between the ages of 7 and 16 had been involved in sexual delinquencies, there was "not a single instance of a known sex violation in adult life"; and of 148 additional cases, all of whom at the same age had been involved in both sexual and other offences, only 8 committed known sexual offences (of a minor type) in adult life, whereas no less than 25% committed further non-sexual delinquencies. Doshay states that the most frequent sexual offence (in over 40% of his cases) involved sodomy with adult men, older and younger boys, or with girls, and observes that "these practices . . . ought not, when occurring among juveniles, to be regarded in too morbid a light, nor should the boys be considered 'perverts' or 'homosexuals,' as noted in some of the texts. The vast majority of offenders engage once or a few times in these unwholesome affairs and turn from them spontaneously with disgust, shame, or fear of

exposure. . . . Of 256 cases, only two . . . revealed such deep interest in and craving for homosexual practices as to warrant the designation of 'homosexual' (and, one may add, the assumption of a fixed inherent predisposition). These findings are largely confirmed by the very thorough investigations of Bender and Blau,<sup>4</sup> and Rasmussen (in girls).<sup>7</sup>

(4) Finally, in attempting to evaluate, in adult homosexuals, the aetiological significance of alleged early seduction or assault (particularly where the history is based on relatives' accounts or official records of the patient's evidence as a child), it is necessary to bear in mind the notorious unreliability of children's evidence, especially with regard to sexual matters, which has long been stressed by many medico-legal authors.<sup>8, 9, 10</sup> The child is frequently incapable of differentiating reality from fantasy (and this may equally apply to the adult's "reminiscences"). Furthermore, the relatives of an adult homosexual who is involved in legal action may be very ready to assert, in reply to legal or medical inquiries, that such a "sexual trauma" was responsible for his present predicament, just as others may, with equal force, proffer "evidence" of physical trauma as the alleged cause of cancer or of mental illness.—I am, etc.,

R. H. AHRENFELDT.

London, S.W.3.

#### The Bedtime Meal

SIR,—“Milk and biscuits at bedtime are the cause of tonsils and adenoids”—is there any truth in so extreme a statement? A bedtime meal is followed, like any other, by the gastro-colic reflex. That in its turn is followed shortly by the filling of the rectum. But, except in infants, there the sequence ends. The final event, evacuation, is discouraged in early childhood and its inhibition becomes habitual. The rectum remains full all night, as is now usual, instead of empty, as is normal. Thus the astringent functions of the lower bowel are in play for some hours. Nothing more happens until, after breakfast, the rectum is filled still further and the sequence terminates in the ordinary way with the morning action. But the unduly firm consistency of the stool calls for a lubricant, which is supplied. The call for mucus is responded to—in the rectum, where it is needed—but the response to that call does not discriminate accurately between the sites needing supply. The nose and throat are apt to receive mucus at the same time as the rectum.

If the only result of the twelve-hour constipation were an occasional sneeze or a brief rhinorrhoea, the penalty might be thought negligible. But the constantly recurring exudation of a little mucus makes the nasopharynx more liable to receive and harbour infective organisms. That chronic catarrh should result and the tonsils enlarge, as armament factories do in war-time, is to be expected—in the way of attack and defence.

To enucleate the tonsils because they have responded to the call is nowadays seen to be bad practice; for, intact, they protect the child—against infantile paralysis certainly and, likely, against a host of other pathogens. Removal is reserved for any that are overwhelmed and stuffed with pus or “cheese” and for those few that are seriously obstructive. But *caveat sanitatis custos*. I have removed, thinking them guilty, tonsils which have proved innocent, and felt shame to take the county council's guinea. I tried to find consolation in Sir Thomas Browne: “Where I do him no good methinks it is scarce honest gain, though I confess 'tis but the worthy salary of our well-intended endeavours.”

How come the children to tolerate the twelve-hour constipation? It is certainly because their food is denatured. From the wheat destined for bread half the offals are taken. That is 15% of the weight of the grist. From that destined for manu-

facturing flour all the offals are still taken, just as they were for the pre-war flour. All the crease-dirt is removed from both. “Offals” and “crease-dirt” are opprobrious words for items of our optimum diet. In the first are the cellulose, some of the semolina, and all the vitamins. The second consists of the minerals the plant has sucked from the soil and stored under the crease in the seed. Deprived of these the gut is languid. That answers the question.

If the child's supper were prepared from the whole grain, ground finely if you will, and made into any chosen form—bread, biscuits, wheaten porridge (though for that it should be merely broken into rather large fragments), or creed and made into frumenty, which is good but forgotten—and if before bed the final reflex of the digestive sequence, the action, were completed, all would be well. For this to happen there must be some interval. Theseus (*A Midsummer Night's Dream*) asked:

“What dances shall we have  
To wear away the long age of three hours  
Between our after-supper and bed-time?”

That is too long, but Shakespeare's hint deserves attention in the nursery.—I am, etc.,

Holmes Chapel, Cheshire.

LIONEL JAS. PICTON.

#### R.M.B.F. Christmas Appeal

SIR,—I gratefully acknowledge many generous contributions towards this year's Christmas Gift Fund, but we are still far short of the sum needed to ensure that all of our regular beneficiaries are remembered. May I make a further appeal to those readers who are in sympathy with our work and who have not yet sent a contribution to forward their donations to: Royal Medical Benevolent Fund, Christmas Gifts, 1, Balliol House, Manor Fields, Putney, London, S.W.15, as soon as possible, as the distribution of gifts is made some days before Christmas.—I am, etc.,

ALFRED WEBB-JOINSON.

President, Royal Medical Benevolent Fund

#### The Lazy Eye

SIR,—May I venture to suggest that the wider implications of the discussion as to the value of occlusion in the treatment of “amblyopia” in children merit further study. Recent surveys of recruits called up under the national service scheme show that 6–8% manifest defects of sight as gauged by (uncorrected) visual acuity of not higher than 6/18 (Snellens) in one eye. Thus, after elimination of congenital and other factors, some 5% of the young male population have by the age of 18 incurred an “amblyopia” associated with squint or high refractive error.

A large proportion of these men state that either they have never had their eyes “tested” or else that they have joyfully discarded their glasses at the first opportunity. The recent discussion held at Leeds by the School Health Service Group of the Society of Medical Officers of Health concerning “Ascertainment of Visual Defect in Children” (*Public Health*, 1947, 60, 215) would indicate some of the ways to tackle this very real problem.—I am, etc.,

London, S.W.1.

G. C. DANSEY-BROWNING.

#### Ourselves and the Russians

SIR,—You published (Aug. 30, p. 339) a leading article entitled “Ourselves and the Russians” in which you criticized an article in the Soviet periodical *Meditsinsky Rabotnik* of July 3, 1947. In the Soviet article Dr. Radbil had castigated the *B.M.J.* for what he described as its “sham political neutrality.” At the time I was impressed by the spirited reply of the Editor of the *B.M.J.*, though the sneering manner in which Dr. Radbil was referred to personally made me wonder how the quotations from his article would have sounded in their original context. Unfortunately the *Meditsinsky Rabotnik* cannot easily be referred to in this country, and it was finally only owing to the courtesy of the Editor of the *B.M.J.* that I was able to see the Soviet article.

I have no desire now to open a discussion of the merits (or demerits) of either article, and, indeed, having read both articles, I would be perfectly prepared to defend either—

**AMECHOL**

TRADE MARK

BRAND

Acetyl-β Methyl-choline Chloride

An effective parasympathetic stimulant having a more pronounced action on the cardiovascular system.

Of service in the treatment of scleroderma and vasospastic conditions of the extremities, including Raynaud's disease and chronic ulcers; also in auricular paroxysmal tachycardia and locally in the treatment of chronic rheumatoid arthritis.

**MORYL**

TRADE MARK

BRAND

Carbachol

A synthetic analogue of acetylcholine with a more specific influence on the gastro-intestinal tract. Has the advantage of being more prolonged and more powerful in its action.

Of particular value in post-operative intestinal stasis and urinary retention, "Moryl" is also effective in eclampsia, pre-eclamptic conditions, hypertonia, anxiety neurosis and tobacco amblyopia.

Applied locally in atropic rhinitis and as a miotic in glaucoma.

Full details of the above

By Appointment  
Suppliers of Aga Cookers to H.M. The King

## The Aga Cooker for Doctors

### NEW PRIORITIES SCHEME

IN THE NATIONAL interest, Aga Heat Limited have inaugurated a scheme of priority deliveries of Aga Cookers and Water Heaters, as follows:—

(1) Exports (2) Farmers (3) Doctors

The reasons for the first and second of these priorities are obvious. British exports must be increased to the utmost, if the country is to be saved from disaster; farmers need every help in their effort to make the country more nearly self-sufficient in food.

Of all servants of the public, doctors—and frequently also their wives—are the most overworked. It is therefore nationally desirable that they should have prior claim to any household equipment that saves labour and in general makes domestic conditions more agreeable. The Aga requires only a couple of minutes' attention a day, and saves any amount of domestic mess and worry.

Many doctors require cooking and water-heating facilities at all hours. The Aga burns continuously and so is always ready for immediate use, day and night, without extra trouble or increasing the fuel consumption.

In relation to their services to the community, few doctors can be said to be lavishly paid. The Aga cuts household fuel-consumption and fuel-bills by anything up to 60%. Aga Cookers are not, as some people seem to think, luxury toys for the well-to-do, but an engineering invention of national importance. Incidentally, besides saving solid fuel, they also relieve the load on gas and electricity undertakings.

For these reasons, Aga Heat Limited believe that the inclusion of doctors in their priorities scheme benefits the country as a whole.

AGA HEAT LTD.

(Proprietors: Allied Ironfoundries Ltd.)

has won the approval of Doctors everywhere

TAMPAX LTD., BELVUE ROAD, NORTHOLT, MIDDLESEX

TRADE MARK

**'SULPHATRIAD'**

BRAND

*compound sulphonamide tablets*

'SULPHATRIAD' contains, in each tablet:

sulphathiazole ..	0.185 gramme
sulphadiazine ..	0.185 gramme
sulphamerazine ..	0.130 gramme

We are pleased to announce that supplies of 'SULPHATRIAD' are now available through the usual trade channels.

'SULPHATRIAD' is suggested in the treatment of acute infections due to pneumococci, gonococci, meningococci,  $\beta$ -haemolytic streptococci, *Bact. coli*, *H. ducreyi* and in gas gangrene. It may also be used as an adjuvant to penicillin therapy in grave *S. aureus* infections and in the treatment of localised staphylococcal infections such as boils, carbuncles and whitlows.

Since the solubility in the urine of each of the constituents of 'SULPHATRIAD' is not affected by the presence of the other two, the risk of renal complications such as crystalluria during treatment with this combination of sulphonamides is greatly reduced. Such a combination may also have certain advantages from the point of view of therapeutic activity.

L.A.B.

rather would have been until I opened the *B.M.J.* of Oct. 18 and read the leading article on "Genetics and Science in the U.S.S.R." (p. 616). This is an important subject, and Hudson and Richens have, as you say, performed a useful service in expounding the views of the opposing schools in their book *The New Genetics of the Soviet Union*. Dealt with in this "temperate and impartial" way, it would seem clear that Lysenko and his followers have allowed their enthusiasm for a new idea to outstrip the conclusions that can reasonably be drawn from their experiments. Dealt with in the manner of your leading article the only effect is to take the *B.M.J.* out of the class of scientific periodicals and align it with that section of the Press which is devoting itself to spreading international hatred.

What exactly did you wish to say? That Vavilov, Levitsky, etc., were sentenced for their scientific beliefs? If this was your intention, it is odd that you should choose as your witness Dr. Darlington, whose partiality is evidenced by his statement in *Discovery* of February, 1947, that "the leading Russian geneticists" . . . have been liquidated in the course of this long political intrigue. These are no longer questions which can be argued about in Russia. For all those who have been prepared to argue have been put away." Hudson and Richens (whose book you praise) point out that Zhebrak and Serebrovski have been "consistent and fearless critics" of Lysenko and that many others, whom they name, have frequently published papers expressing the views generally accepted elsewhere. No, presumably your intention was the more generous one of providing stronger evidence for Dr. Radbil's next article.—I am, etc.,

London, W.1.

RICHARD DOLL.

### Medical Photography

SIR,—The letter from the Deputy Chairman of the Medical Group of the Royal Photographic Society (Nov. 1, p. 710) referred to the excellent reproductions in the photogravure plate in the *Journal* of Sept. 27, and made a plea for individual acknowledgment of the medical photographer. The gastroscopic pictures included in the plate were photographs made from paintings by Miss D. Barber, and unfortunately her name was omitted during the photographic process. I am glad of this opportunity to apologize for the omission, and I wish to support their request for encouragement of medical photographs—and for medical artists too. There is a real need for developing this ancillary service for hospitals, not only for illustrating publications and clinical meetings but also for aiding the long-term study of the natural history of disease. It is hoped that other county authorities will follow the example of the Middlesex County Council in appointing whole-time artists and photographers.—I am, etc.,

London, N.W.10.

F. AVERY JONES.

### POINTS FROM LETTERS

#### Edible Fungi

Major-Gen. A. H. HARRY (Bombay) writes: I read with interest the article in the *Journal* of Aug. 23 (p. 304) "Some Edible Fungi," by Dr. John Ramsbottom. . . . I remember reading some years ago in, I think, a popular magazine that if all the following points are satisfied the mushroom is certainly edible: (1) It must be gathered in open spaces—e.g., a wind-swept meadow; (2) the skin must peel readily from the cap; (3) the stalk must be solid and not hollow; (4) the gills must not touch the stalk—i.e., there must be a complete circular space, however narrow, between gills and stalk. I have myself eaten fungi which satisfy all these points, but have often felt, while discarding others that failed to do so, that I was being overcautious. Will Dr. Ramsbottom be pleased to give us some practical working rules, and to confirm or refute the four tests given above?

#### The Last Straw—Unholy Smokes

Dr. IAN N. SAMUEL (London, S.W.11) writes: Perhaps Dr. Stokes's (Nov. 1, p. 710) patients find solace in smoking to make up for their irritation in seeing his door covered with notices. Although I agree that it is an imposition to expect medical men to sign such forms as the pensioners' tobacco form, it is obvious that a refusal to sign hurts only the applicant: the bureaucrat remains unscathed. The other named persons empowered to sign the form are generally out of reach for the patient. I know the police won't sign, on the grounds that they have no personal knowledge of the applicant. . . .

## Obituary

### SIR ARTHUR STANLEY, G.C.V.O.

The Hon. Sir Arthur Stanley, G.C.V.O., G.B.E., C.B., died at his home in Eastbourne on Nov. 4 at the age of 77. He had been closely associated with St. Thomas's Hospital for twenty-six years and for an even longer period with the British Red Cross Society and the King Edward's Hospital Fund for London. His death brings to an end a long-sustained and unselfish devotion over many years to the welfare of the wounded and the sick.

The Hon. Arthur Stanley, third son of the sixteenth Earl of Derby, was educated at Wellington and began his career in the Diplomatic Service. He left the service for a short time to become private secretary to Mr. Balfour, but by 1895 he was third secretary in Cairo under Lord Cromer. In 1898 he was elected to Parliament by the Ormskirk Division of Lancashire, which he continued to represent until his resignation in 1918. His connexion with the King Edward's Hospital Fund for London began in 1908. He was made chairman of the British Red Cross Society in 1914, and two years later he was elected the first chairman of the Royal College of Nursing. When in 1917 he also became Treasurer of St. Thomas's Hospital he decided to leave Parliament and to devote his energies entirely to the care of the sick and of those wounded during the 1914-18 war. His services were recognized by a presentation in 1919, when Princess Christian paid tribute to his chairmanship during the war years of the joint council of the British Red Cross Society and the Order of St. John of Jerusalem. Edinburgh made him an honorary F.R.C.P. and Leeds awarded him its honorary LL.D. His devoted work for St. Thomas's Hospital and for the British Red Cross Society came to an end only in 1943, when failing health compelled his retirement.

### W. H. KAUNTZE, C.M.G., M.D., F.R.C.P.

#### Chief Medical Adviser, Colonial Office

Dr. William Henry Kauntze died at Woking on Nov. 4 at the age of 60 after a painful illness courageously borne. Educated at Victoria University, Manchester, and London University, he graduated in 1911 and after holding resident appointments at the Manchester Royal Infirmary and in Salford he joined the West African medical staff in Nigeria in 1912. In the war of 1914-18 he served in both the West and East African Forces. In 1919 he was appointed senior bacteriologist and deputy director of laboratory services in Kenya Colony and remained there until 1932, when he was promoted to be director of medical services, Uganda. He had proceeded M.D. in 1921 and he was elected F.R.C.P. in 1945. In 1941 he was appointed assistant medical adviser to the Colonial Office and in 1944 became chief medical adviser. He was awarded the M.B.E. in 1918 and the C.M.G. in 1937. He was also a Knight of the Order of St. John of Jerusalem. As chief medical adviser to the Colonial Office he was *ex officio* chairman of the Honorary Managing Committee of the Bureau of Hygiene and Tropical Diseases from 1945 onwards, and in this capacity he was concerned with the publication of the *Bulletin of Hygiene*, the *Tropical Diseases Bulletin*, and the *Bulletin of War Medicine*.

Kauntze was a man with the highest ideals who never spared himself in the work of the service which he loved and to which he subordinated all things. After his appointment in London he travelled widely in the colonies, visiting Africa, the West Indies, and the Far East to see for himself conditions in these places and to discuss possible improvements. His capacity for work was very great and he drove himself relentlessly. His last tour in the Far East undoubtedly precipitated his final illness, and, although he was aware of this probability, his high sense of duty compelled him to carry it out. As a result of his journeys and his studies he was convinced that in the application of the principles of social medicine lay the solution of the tropical problem, and even at the end in periods when free from pain he strove to further this policy. With his deep insight into colonial problems he realized that for real success the co-operation of the local people was essential,

and he was a strong advocate for higher education in colonies and insistent that the standard be the highest attainable. He had no use for second bests. Convinced of the necessity of international action in matters of health, he was keenly interested in the building up of the World Health Organization and was a member of the British delegation at all meetings of the Interim Commission. Setting before himself only the highest standards, he expected the same lofty ideals from others, and it was a privilege and inspiration to work with him.—A.M.W.R.

#### FRÉDÉRIC F. BURGHARD, C.B., M.D., M.S., F.R.C.S.

Mr. Frédéric F. Burghard died in Cambridge on Oct. 31 at the age of 83. He had been on the staff of King's College Hospital from 1889 until his retirement in 1923, when he was appointed consulting surgeon to the hospital and emeritus lecturer in clinical surgery in the medical school.

Frédéric François Burghard was born on Feb. 27, 1864, and educated at Christ's College, Finchley, and at Guy's Hospital, where he was awarded the Treasurer's Gold Medal in surgery. He graduated with first-class honours in 1886, and took the London M.S. in 1887 and the F.R.C.S. in 1888, a year before he proceeded M.D. At Guy's Hospital he was resident obstetrical assistant, house-surgeon, and in 1888 surgical registrar. He was appointed assistant surgeon to King's College Hospital in 1890. It will be recalled that Sir Joseph Lister only retired finally from King's College at the end of the summer session in 1893. Mr. Burghard was promoted surgeon to the hospital in 1898, and in 1902 became teacher of operative surgery in King's College. He was actively concerned in the movement which led to the transfer of the hospital from Portugal Street, and in 1904 represented the Watching Committee of the Medical Board on the Building Committee of the new hospital at Denmark Hill. It was mainly due to his efforts that the various clubs and societies of King's College Hospital were amalgamated to form the Clubs and Societies Union of King's College Medical School. He was elected first president of the Union and held that office until his retirement. For many years also he was president of the hospital rugby football club. In his student days he had played for the Guy's Hospital XV.

During the 1914-18 war he was a colonel in the A.M.S., and consulting surgeon to the B.E.F. from 1914-16. In 1919 he became senior surgeon to King's College Hospital and lecturer in clinical surgery; three years later he was made director of surgical studies. At this time, too, he served on the committee of management of the hospital. Mr. Burghard was a member of the council of the Royal College of Surgeons of England from 1915 to 1923 and was for some years a member of the Court of Examiners. For many years he was one of the examiners in surgery at Cambridge and at London University. With Sir Watson Cheyne, Burghard wrote a *Manual of Surgical Treatment* and he also edited a *System of Operative Surgery*. He had been elected a Fellow of King's College in 1909, and on his retirement in 1923 he was appointed consulting surgeon and emeritus lecturer in clinical surgery. On retiring from practice he went to live at Rolleston, Burton-on-Trent, where he became consulting surgeon to the Burton-on-Trent General Infirmary.

#### A. M. WEBBER, M.S., F.R.C.S.

Mr. Alexander Moxon Webber, for a number of years one of Nottingham's most eminent surgeons, died at his home in Sandown, Isle of Wight, on Oct. 26. He retired and went to live there in December, 1945, but before then he had been in failing health for some time. He was born in South Africa, and he came to England and received his medical education at Guy's Hospital. He graduated M.B., B.S. in 1903, and two years later he took the London M.S., and in 1906 the F.R.C.S. The following year he settled in Nottingham in partnership with Mr. Chicken, who was one of the surgeons at the General Hospital. At Guy's Hospital Mr. Webber had held the post of house-surgeon and obstetric resident. He was also clinical assistant at Great Ormond Street for a short period.

After settling in Nottingham he rapidly became well known and was appointed in succession assistant surgeon to the Children's Hospital, to the Nottingham General Hospital, and

to the Women's Hospital, and later on he rose to the full staff. In the first world war he served abroad with the R.A.M.C., principally in East Africa, with the rank of major. Mr. Webber was always an active member of the British Medical Association. He was secretary of the Nottingham Division from 1922 to 1925, and chairman in 1931-2. He had been a member of the Council, and had served on a number of central committees. He was also a representative at the A.R.M. for ten successive years from 1919-28.

R.G.H. writes: My closest association with Mr. Webber was, of course, when he acted as secretary for the Annual Meeting in Nottingham and I was president. Nobody could have had a better secretary. He was a born administrator, and in addition to that he never quarrelled with anyone, so that at the Nottingham meeting we never had any dispute before or during the meeting and everything went smoothly and well. All this was due to Mr. Webber, and he was most ably supported by a very clever, capable, and devoted wife, who survives him. As a medical colleague he was always understanding and very human. He had a most retiring nature and never pushed himself forward. I never heard him say an unkind thing about anyone, and I have never known a surgeon who was better liked by his patients. In Nottingham he is greatly missed and will be long remembered.

#### JOHN CHARLES, M.D.

Dr. John Charles, who died suddenly on Oct. 15 at the age of 83, was born in Elgin. In 1888 he graduated M.B., C.M. at the University of Glasgow, and proceeded to the doctorate in 1895, with commendation. After qualifying, he took an assistantship in Sunderland before starting in general practice at what was then just a small colliery village at Stanley, in Durham, and there he lived and worked for the remaining fifty-two years of his life. During that time he saw the place grow from a collection of houses round the colliery until it became one of the twelve largest urban areas in the county. For years Dr. Charles's partner was his brother-in-law, Dr. Dewar. It was a typical colliery practice, but of rather a new type. For many years the medical work in the colliery districts in Durham and Northumberland had been carried on largely by unqualified assistants who lived in the hamlets round about the collieries while the principal, who might employ several of these assistants, would reside in the older, well-established villages or small townships. But just about the time that Charles started in practice one of the Medical Acts had brought that system to an end, and the opportunity was provided for a new and better arrangement. The miners were not slow to appreciate the advantages of the change, and from the outset Charles set out to give them a first-rate service. An early event after his arrival in Stanley was a dispute between the colliery doctors and the miners regarding the amount of the fortnightly subscription to the medical fund. The contribution, which was deducted at the colliery offices from the men's pay, was 6d., which, as a result of prolonged and tedious negotiations, was eventually raised to 9d. The dispute affected considerable areas of the northern coalfield.

The cause of the colliery doctors was loyally championed by Rutherford Morison, who was then rapidly becoming the leading surgeon in the North and with whom Charles was closely associated as secretary of the Colliery Practitioners' Association. A great deal of work was involved and many meetings were arranged and attended up and down both counties. At that time there was no easy transport by motor-car, and local train services were poor, so that many of the journeys had to be made by bicycle, which was no easy task in the hilly parts of County Durham. Morison and Charles formed a good combination, and their work was appreciated.

Dr. Charles was devoted to his professional work and carried out his duties as a colliery doctor conscientiously and systematically. He was one of those who kept in touch with the work at the old Infirmary in Newcastle and used often to come in to see his patients. Over the years Charles acquired an intimate insight into the miner's mind based on a close knowledge of his way of life with its difficulties and dangers. Strikes, lock-outs, and political upheavals deeply affected the colliery doctor, and the calm, steadying effect of men like Charles was

then invaluable. Whenever problems had to be adjusted in the relationship of doctor and miner he was called in as consultant, adviser, and mediator. One particular hazard of the miner's life was experienced in February, 1909, when an explosion at the West Stanley Colliery resulted in the loss of the lives of 168 men and boys. Charles took part in the grim work of rescue, descending the pit at an early stage after the explosion and remaining underground as long as there was a glimmer of hope that any of the victims might be found alive.

Early in his career Dr. Charles began an association with the Consett Division of the B.M.A., for which he acted as honorary secretary for a quarter of a century. All the honours of the Division and of the North of England Branch eventually came to him, and he was President of the Branch in 1923-4.

Although Charles was mild and not in the least aggressive, he was a man of sterling courage and was always prepared to back up his own opinion when he felt he was in the right. When the National Health Insurance scheme was first under discussion there was a great deal of opposition in the North, but at a large and obviously hostile meeting Charles had the courage to get up and make a speech in support of what he conceived were some valuable features in what was then a novel scheme. About 1904 he began to interest himself in local government and served on the district council for some nine years. He was also for some years chairman of the local municipal association. In 1923 he was made a justice of the peace, and he took a great interest in his magisterial duties until well on in his seventies. He was also one of the originators and, for the long period of 44 years, the founder-chairman of the local building society.

He married the sister of his future partner in 1892, and his widow survives him. His family consists of two sons and a daughter. The sons both followed his profession, but the younger predeceased him in 1937; the elder took up a public health career, and is now in the Ministry of Health. Until a few months ago Dr. Charles enjoyed wonderful health and was able to carry on many of his activities. His death came suddenly and unexpectedly, and was a severe blow to the neighbourhood, where he was so well known, respected, and beloved.—G. G. T.

Dr. HERBERT HENRY WARREN died on Oct. 11 at the age of 67. A son of W. H. Warren, professor of engineering in the University of Sydney, he graduated at Birmingham in 1907, and after a period as resident medical assistant at Jaffray Hospital he settled in Portsmouth in 1909 in partnership with the late Dr. Marwood. During the 1914-18 war he served in the R.A.M.C. with the rank of major and was mentioned in dispatches. He had a lifelong connexion with the St. John Ambulance Association, and became county surgeon in 1942, being made an officer of the Order of St. John of Jerusalem only a few months ago. He had been secretary of the Portsmouth Division of the British Medical Association from 1925-7 and chairman from 1929-30. He was president of the Southern Branch in 1944-5, and on seven occasions had been a representative at annual meetings.

Dr. A. Brownlee writes: By the death of Mr. J. W. GEARY GRANT there has passed away one of the ablest surgeons associated with Cardiff. Geary, as we affectionately knew him, retired from active practice about a year ago to live in Weymouth. His health was failing when he left Cardiff. He began to get heart attacks, and it was obvious to his intimate friends that he could not go on for very long. The end came suddenly on Oct. 23, with symptoms of cerebral haemorrhage and cardiac failure. On his professional attainments I do not intend to dwell; these speak for themselves. He came to Cardiff Royal Infirmary in 1900 as resident medical officer. After a year's residency he went into general practice in Llanwrtyd-Wells for some years. Returning to Cardiff about 1909, he became assistant surgeon and later surgeon to the infirmary. He held many other appointments, including those of surgeon to Porth Hospital, Glan Ely Hospital, and several others. But it was of his private life that I wish to speak. Geary Grant was one of the straightest men I ever knew and was utterly incapable of performing a mean action of any kind. He will be sadly missed by his widow and daughters, to whom the deepest sympathy is extended in their loss.

## Medico-Legal

### CERTAINTY IN SURVIVORSHIP

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Since the new property legislation of 1925, where two or more persons die in circumstances which make it uncertain which of them survived the other or others, the deaths are presumed to have taken place in order of seniority and the court supposes, for the purpose of distributing the estate, that the younger survived the elder. The working of the rule was illustrated by the well-known cases in which a number of persons died in the same bomb explosion, and the House of Lords delivered a set of lengthy, highly involved, and conflicting judgments on whether two deaths can at law ever be simultaneous.<sup>1</sup> A recent case concerning not air-raid deaths but a double gas-poisoning dealt with the evidence required to prove certainty or uncertainty.<sup>2</sup>

An old couple were found by a neighbour dead in their kitchen, with the tap of the gas-oven slightly turned on and a cooked joint in the oven. The medical evidence was conflicting. Dr. John Taylor said that the blood of the husband, aged 83, was 57% saturated. He was healthy except for some cerebral atheroma. The wife, aged 75, was healthy except for granular kidneys, and her blood was 47% saturated. The witness therefore concluded that she had died first. The concentration of carbon monoxide in the blood tended to rise with the length of exposure and after death no more gas was absorbed; therefore, when two people were exposed to the same concentration, it was reasonable to suppose that the person with the higher concentration died later than the other. Dr. R. D. Teare said that errors might arise before a sample of blood reached the laboratory: the gas in the blood escaped, and so the analysis revealed a lower figure than it would have given at the time of death. The error varied with the amount of air left in the bottle, the degree of shaking of the bottle in transport, and the time intervals between death, the taking of the specimen, and the analysis. The concentration generally accepted as lethal was between 60 and 80%—much higher than that in either sample. He therefore said that Dr. Taylor's figures could not represent the concentrations in the bodies of the deceased persons at the time of death, that gas had been lost from both specimens, and that the figures were no guide to which of the two had died first.

Sir Bernard Spilsbury confirmed that 57% was a low saturation in a fatal case, and said he was very doubtful whether 42% saturation could cause death. The low concentrations raised a suspicion of a loss of gas from the samples before they were tested. This, he said, occurred readily unless the samples were collected with great care. Like Dr. Teare, he did not regard the tests as a reliable indication of which of the two died first: nor did he find any medical facts to indicate which would be likely to die before the other, except the greater age of the man. Dr. Taylor, in reply, testified that some gas might well have been lost during the two days between the taking and the testing of the samples. In any event, however, it was reasonable to suppose that both samples were affected to the same extent. The considerable difference between the two could not have been accounted for by anything that had happened after the death. He added that once the brain cells had been sufficiently damaged by the effect of the gas, death could occur even after all traces of gas had been removed from the blood. The degree of damage would depend on the period of exposure as well as on the concentration. For this reason the percentages of saturation were relatively significant and, apart from any other circumstances, indicated a strong probability that the wife died first.

The learned judge, Mr. Justice Jenkins, quoted some of the opinions of the Law Lords on the nature of "uncertainty" within the meaning of the section. Lord Simon had said that it was an uncertainty not removed by evidence leading to a definite and warranted conclusion. Lord Macmillan had said it denoted a reasonable element of doubt. The judge thought

<sup>1</sup> *Hickman v. Plessery*, 1945 A.C. 304.  
<sup>2</sup> *Re Bate*, 1947 2 All E.R. 418.

that, to come to a definite conclusion that the husband survived his wife, it was not enough for him merely to find that that was the more reasonable conclusion. He must come to a conclusion of fact on grounds that so far outweighed any grounds for a contrary conclusion that this could be ignored. He could not do so on the present evidence with its conflict of medical opinion. As there was no reliable ground on which he could find that either died before the other, the presumption must prevail that the younger, the wife, survived the elder, her husband.

## Medical Notes in Parliament

### Medical Organization in the Services

On Nov. 5 Dr. SEGAL asked when the Minister of Defence would institute a unified medical organization for the three Defence Services, in order to economize in manpower and medical supplies. Mr. ALEXANDER replied that, as he had said on July 9, it had not yet been established that the institution of a unified medical service was to be preferred to the maximum degree of co-ordination between the existing Services.

Sir HENRY MORRIS-JONES said officers of the R.A.F. and the Army wrote to the medical journals week by week to say they had nothing to do. (Under the heading "Working Day in the Services," letters have appeared in the *Supplement* of Oct. 18, p. 93; Nov. 1, p. 101; and Nov. 8, p. 113.)

Mr. ALEXANDER said he had seen such comments, but they did not agree with the advice given by the senior professional advisers. He added that steps were already being taken to co-ordinate the specialist services of the three Defence Forces.

**Release of Medical Officers.**—Col. STODDARD-SCOTT asked on Nov. 4 whether in view of the Government's decision to reduce the size of the Services Mr. Bevan would reduce the age limit of medical and graded specialists now liable to be conscripted up to the age of 40, in view of the shortage of specialists in civil life. He further asked Mr. Bevan if he would accelerate the release of doctors and dentists now serving with the Forces; and if he would assure the House that there was a proportionate reduction in the number of those now conscripted in view of the shortage of doctors and dentists in civilian practice. Mr. JOHN EDWARDS replied that Mr. Bevan was advised on the recruitment and release of doctors by the Medical Priority Committee under the Chairmanship of Dr. Haden Guest. He awaited its advice on the effect of the recently announced reductions in the size of the Forces.

**Veneral Disease.**—Dr. SEGAL on Nov. 4 asked for figures for the incidence of venereal disease among Army personnel in the United Kingdom and the various theatres overseas for each of the first three quarters of 1947. Mr. SHINWELL, in reply, circulated this table:

JANUARY-JUNE, 1947  
(Quarterly Rates per 1,000 Strength)

	1st Quarter	2nd Quarter
United Kingdom .. ..	5.2	5.5
Germany .. ..	36.4	34.8
Italy .. ..	23.7	34.1
Austria .. ..	36.8	34.7
Middle East .. ..	6.7	27.7
Far East .. ..	32.6	46.8
Japan .. ..	61.2	

Figures for the third quarter are not yet available. As a result of administrative changes, Middle East includes Malta and East Africa as from April 1, 1947. The sharp fall in the second quarter is at least partly attributable to a reduction in the number of troops in Greece, where the rate of venereal disease was high. The number of troops in Japan is small and sharp fluctuations are therefore to be expected.

**Calories.**—The most recent dietetic survey results (July, 1947) show an average intake of 2,287 calories for working class households from food eaten at home. The figure for July, 1946, was 2,282 calories.

**Calories Again.**—Dr. EDITH SUMMERSKILL said on Nov. 3 that the estimated national average calorie intake from all foods, rationed and unrationed, was 2,870 per head per day. Consumption by individuals within this total differed widely. To calculate the average daily calorie intake of rationed and points goods, and hence that of unrationed foods, would involve lengthy calculations which she did not think would be justified, since the result would have no relation to individual cases.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on Oct. 16 the following degrees were conferred:

B.M.—W. L. Gordon, G. E. Mann, N. C. Hughes Jones, O. M. Wong, Mrs. Mercy I. Healey, D. C. Bernstein (in absence).

### UNIVERSITY OF LONDON

The following awards have been made to students of the course for the Academic Diploma in Public Health at the London School of Hygiene and Tropical Medicine during the session 1946-7: *Chadwick Prize*, Dr. J. H. F. Brotherston; *Association of Industrial Medical Officers' Prize*, Dr. J. N. Morris; *Hecht Prize*, Dr. M. E. R. Balfour and Dr. T. McL. Galloway.

### UNIVERSITY OF EDINBURGH

At a Graduation Ceremony on Oct. 25 the degree of Ph.D. (in the Faculty of Medicine) was conferred on Y. Y. Akrawi, M.B., Ch.B., and the degree of B.Sc. in Pathology (in the Department of Pure Science) on G. M. Wilson, M.B., Ch.B. (with first-class honours) G. A. C. Summers, M.B., Ch.B., B.Sc., has been admitted to second-class honours in pathology, after graduation.

The following diplomas were granted:

D.P.H.—K. A. Brahmabhatt, \*V. D. R. Martin, \*J. A. Miller.  
DIPLOMA IN MEDICAL RADIOLOGY.—\*T. A. B. Mason.

\*In absentia.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

A series of lectures on anatomy, applied physiology, and pathology will be delivered at the College (Lincoln's Inn Fields, London, W.C.2) on Mondays to Fridays from Nov. 24 to Dec. 19, both dates inclusive, at 3.45 p.m. and 5 p.m. each day. The fee for the course is £10 10s.; but Fellows and Members of the College and Licentiates in Dental Surgery will be admitted for £8 8s. Admission cards may be obtained from the secretary of the Postgraduate Education Committee of the College.

A series of lectures in ophthalmology will be delivered daily at the College from Monday, Dec. 29, to Tuesday, January 13, 1948, at 5 p.m. (both dates inclusive, but Saturdays and Sundays excepted). The fee for the whole course is £5 5s. (single lecture, 10s.), but Fellows and Members of the College and Licentiates in Dental Surgery will be admitted for £3 3s. (single lecture, 7s. 6d.). Applications should be sent to the Secretary of the Postgraduate Education Committee of the College.

The Council of the College invites applications by Dec. 31 for the Sir William H. Collins Professorship of Human and Comparative Pathology, at a salary of not less than £2,000 per annum. Particulars and terms of appointment may be obtained from the Secretary of the College.

The Museum of the College in Lincoln's Inn Fields, London, W.C.2, is again available for the use of medical practitioners, medical students, etc. It is open daily from 10 a.m. to 5 p.m. (1 p.m. on Saturdays), but visitors are warned that on account of shortage of accommodation the Anatomy Museum is sometimes in use during parts of the afternoon for lectures or meetings. Revised catalogues are in course of preparation and in the meanwhile specimens are marked with descriptive labels.

The collections are still much depleted by enemy action, but the following series are sufficiently complete for exhibition: *Anatomy*.—On the ground floor in Room I specimens illustrating the nervous system and integument are arranged and labelled. (In the galleries of this room specimens illustrating other systems are available for study but are not yet permanently arranged or labelled.) *Pathology*.—Diseases of the skeleton; diseases of the nervous system; diseases of the alimentary system; teratology; a special group of selected Hunterian specimens. Other series are still so fragmentary that they are of little value to students.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College, held on Oct. 30, with the President, Lord Moran, in the chair, Prof. F. J. Nattrass, Dr. W. Russell Brain, and Dr. R. D. Curran were elected Councillors. The following were elected representatives of the College: Sir Adolphe Abrahams on the committee of management of the Conjoint Board; Dr. F. S. Langmead on the Central Midwives Board; Dr. G. President, Sir Leonard Parsons, Dr. H. E. A. Boldero, Dr. W. G. Barnard, and Sir Allen Daley on the standing joint committee of the three Royal Colleges; Dr. C. M. Hinds Howell, Dr. M. F. Shaw, Dr. J. B. Harman, and Dr. J. C. Hawksley on the Committee

of Reference; Dr. C. M. Hinds Howell and Dr. J. B. Harman on the Central Medical War Committee; Sir Arthur MacNalty on the Aliens Committee of the Central Medical War Committee (in succession to Sir Robert Hutchison who had resigned); and Dr. J. Hay (re-elected) on the court of governors of the University of Liverpool.

Dr. Marc Daniels was appointed Milroy Lecturer for 1949, his subject being "Tuberculosis in Post-war Europe."

The President announced that the Gilbert Blane Gold Medal for 1947 had been awarded to Surgeon Commander G. H. G. Southwell-Sander, R.N., and the Jenks Memorial Scholarship to M. B. Watts, late of Epsom College.

#### Memberships

The following candidates, having satisfied the Censors' Board, were elected Members of the College:

E. B. Adams, M.B.; G. F. Adams, M.D.; H. St. C. C. Addis, M.B.; K. D. Allanby, M.B.; H. Angelman, M.B.; R. C. Angove, M.B.; J. W. Beattie, M.D.; G. A. Bedwell, M.B.; R. B. Blacket, M.B.; P. J. A. Blaney, M.B.; J. J. Bourke, M.B.; W. H. Bradley, D.M.; J. F. Buchan, M.B.; G. MacG. Bull, M.D.; W. E. Church, M.B.; J. A. K. Cunningham, M.B.; G. R. Davies, M.B.; E. G. Donovan, M.B.; L. Eales, M.B.; V. Edmunds, M.B.; C. H. Edwards, L.R.C.P.; C. G. Fagg, M.B.; Elizabeth de C. Falle, M.B.; H. G. Farquhar, M.D.; E. Fletcher, M.D.; J. O. Forfar, M.B.; T. G. Fox, M.B.; P. Frankel, M.B.; E. S. Frazer, M.B.; A. Freedman, M.B.; O. Garrod, M.B.; J. W. Genard, B.M.; F. S. Gorrill, M.D.; H. J. Hambling, M.B.; H. C. Hamilton, M.B.; G. F. Harrison, M.B., Lieut.-Col., R.A.M.C.; M. F. Hart, M.B.; M. A. Hassanein, M.B.; Hung-chiu Ho, M.B.; Q. J. G. Hobson, B.M.; A. Hollman, M.B.; S. Hunter, M.B.; J. Jacobs, M.D.; D. Jamieson, M.B.; J. M. Jefferson, B.M.; P. B. Kunkler, M.B.; D. N. Lawson, M.B.; D. N. Leeming, L.R.C.P.; J. Lister, M.B.; K. R. Llewellyn, M.B.; P. M. Lohar, M.B.; B. McConkey, B.M.; J. P. McGladdery, M.D.; I. C. K. Mackenzie, M.B.; J. G. Millicap, M.B.; G. E. Milne, B.M.; J. N. Milnes, M.B.; C. H. Naik, M.B.; Catherine A. Neill, M.B.; S. G. Nelson, M.B.; M. H. Oelbaum, M.B.; J. F. Pantridge, M.D.; J. C. S. Paterson, M.B.; Florence R. Pillman, M.B.; J. B. Randall, M.B.; P. C. Reynell, B.M.; J. A. Robertson, M.B.; C. A. Rumball, L.R.C.P.; V. E. Sampson, M.B.; C. G. R. Sell, M.B.; M. L. Sharma, M.B.; J. R. Simpson, M.B.; J. F. P. Skrimshire, M.B.; J. S. Staffurth, M.B.; S. W. Stanbury, M.B.; I. McD. G. Stewart, M.B.; P. E. Sundi, L.R.C.P.; J. Sutcliffe, M.B.; P. H. Sulton, M.D.; R. D. Sweet, M.B.; B. Fitz A. Swynnerton, B.M.; P. E. D. S. Wilkinson, M.B.; I. P. Williams, M.B.; J. M. G. Wilson, M.B.; R. B. Wilson, M.B.; Joan D. Wrigley, M.B.; J. B. Wyon, M.B.; Judith C. M. Yuill, M.B.

#### Licences

Licences to practise were conferred upon 129 candidates (including 30 women) who have passed the final examination in Medicine, Surgery, and Midwifery of the Conjoint Board and who have complied with the by-laws of the College:

K. J. Adams, B. P. Appleby, D. E. Argent, E. M. P. Ball, T. W. Barnes, A. F. Barnett, D. W. G. Bartlett, R. W. A. C. Barton, Barbara Baxter, Kathleen M. Beth, A. Beck, Audrey Beder, Evelyn M. P. Bedwell, J. Bendas, Nancy L. C. Berry, J. B. Binks, T. D. Breninall, D. J. Brewer, Margaret L. M. Bridges, G. B. Brown, G. B. Burchell, Evangeline Burgess, A. R. P. Calder, Emily M. Collingridge, S. Compton, E. P. Cooke, M. H. D. Cooper, D. J. Cowan, I. W. Crown, D. M. Curtis, Phyllis Dagnall, E. T. Dakin, D. W. Davies, A. M. Dickinson, A. E. Dossetor, Evelyn S. Elliott, J. Elstrib, H. R. Erskine, E. J. Fairlie, G. F. Faulkner, R. A. W. Feakes, Rosalind Fellows, Margaret M. F. Fitzpatrick, Mary E. Forester, R. French, P. S. Gardner, F. P. A. Garton, J. Gay, M. Ghousuddin, N. M. Gibbs, Elizabeth M. Gost, D. B. Goss, G. Hacking, Jean Hansell, J. L. Hardman, M. A. Hassman, A. G. Henderson, Mary M. Herley, Miriam Hirtzel, Eleanor M. Hoole, J. B. Howard, Jean A. Infield, L. J. Ison, W. B. James, A. L. Jeanes, J. G. Jeffs, M. S. Johnson, C. Jones-Morgan, Ruth V. Kemp, D. W. Kennard, J. V. Kilby, Alwin C. B. Latham, W. C. Lathbury, R. H. N. Long, D. Lonsdale, Mary A. J. Lourie, K. N. H. Low, W. E. MacBean, D. Y. Mackenzie, D. L. M. McNeill, R. I. Maitland, D. N. Mitchell, D. C. Morley, Sybil M. Murray, Hannah Mushin, Selty S. Natayana, J. E. Noble, H. R. Odlum, E. G. Old, Barbara Oldham, J. H. H. Oliver, R. L. Osmond, R. D. Pearce, Eileen M. Pearson, L. Phillips, B. G. Pickles, A. Pilling, J. S. Porterfield, F. Rassim, W. H. Rees, M. C. T. Reilly, Doreen M. Reside, P. W. H. Robinson, D. J. H. Rogers, J. R. Scholey, B. K. Scott, Margot Shiner, Elisabeth Shoenberg, R. Sloman, R. I. L. Smallwood, C. W. Smith, P. H. A. Sneath, D. J. R. Snow, W. Spector, H. B. Stafford-Kemp, D. P. P. Thomas, B. Towers, E. J. Trimmer, D. K. Tucker, Betty M. L. Underhill, J. H. B. Urmonst, C. W. J. Usher, J. K. Walker, A. L. Farlow, B. M. Watney, F. E. Weale, J. S. Weiner, A. W. Weller, H. D. Yauner.

#### Diplomas

The following diplomas were conferred jointly with the Royal College of Surgeons of England:

DIPLOMA IN CHILD HEALTH.—Isabella M. Almond, L. Apter, M. W. Arthurton, N. C. Begg, Marjorie Bell, P. C. Bhattacharjee, Evelyn L. Billings, Ruth Blackwood, M. P. Bourke, Phyllis E. M. Bowen, Rosemary R. M. Brawmore, Lilian M. Burdiche, Angela E. D. Burns, Mary W. Coxon, D. G. Crawshaw, Agnes A. Crone, D. E. Cullington, Enid Curran, J. E. A. David, Gwendoline E. Davidson, G. K. Dharwal, E. M. Dimock, D. Eglin, H. H. A. Elder, Norah C. Elphinstone, B. E. G. In, H. C. Falcke, O. D. Fisher, S. Ghosh, Mary E. Goodson, R. R. Gordon, Muriel D. Graham, J. Griffith, D. Hilson, Helen C. Humphreys, S. Hunter, A. F. Huston, Margaret Inglish, H. Isenberg, I. P. Jaffe, R. T. Jenkins, S. T. H. Jenkins, G. G. Jones, Megan P. Jones, R. S. Jones, Amy K. Jungswalla, S. E. Keldan, J. J. Kempton, I. Kessel, Beryl E. Lewis, Joyce R. Lewis, J. M. Librach, D. Macaulay, Grace E. McClafferty, W. E. MacLean, R. F. Mages, Margaret D. C. Martin, J. D. H. Matthews, W. R. May, Kate Menashe, J. A. W. Miller, W. J. Moffett, N. G. Mojmudat, I. Morris, Sheila M. Murray, T. N. Nauth-Muir, Sheila M. Niall, L. Pannall, Diana G. Paradise, C. V. Patel, I. E. Phelps, Rosa M. Pigott, J. N. A. Pritchard, H. S. Provis, Margaret Readman, P. A. H. Rivett, Cecilia M. Robinson, Sheenah J. McK. Russell, E. Sanders, M. J. A. Sandström, S. S. Schmulian, Elizabeth M. Sefton, J. Shein, S. C. Sherif, Rosemary J. S. Siegel, J. C. Simson, Margaret Slater, Evelyn A. Souter, M. Stein, J. MacP. Stuart, J. H. Tan, Sheila R. Tange, W. F. J. M. Thom, P. A. Thorp, R. B. Tull, G. S. Udall, Elizabeth G. Vaughan, C. K. J. Vautier, Glenys J. Wade, B. D. R. Wilson, Lydia A. Wilson, E. R. Winton, B. Wolman, L. G. Woods, Marjorie Wright, T. Wright.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—E. Heffernan, J. McClelland, and those whose names were printed in the *Journal* of Oct. 11 (p. 593).

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—The names of the successful candidates for this diploma were published in the *Journal* of Aug. 23 (p. 313) and Oct. 11 (p. 593).

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS.—I. Ap Thomas, E. Batley, J. L. Boldero, J. S. Campbell, P. S. G. Campbell, A. F. Crick, C. G. Edwards, J. B. Fawcitt, D. Hector-Jones, A. K. Lamballe, M. W. H. Mackay, Elsie L. Mettam, W. R. Parker, J. N. Pattinson, E. N. Pearlman, S. P. Rawson, D. Sutton, B. W. Thomas, J. M. W. Wells, C. G. Whiteside.

DIPLOMA IN MEDICAL RADIOLOGY.—K. W. Beetham, D. G. Bratherton, E. C. Easson, J. M. W. Gibson, H. Holden, K. S. Khambata, N. S. Lockyer, J. Li. E. Millen, T. K. Morgan, B. A. Stoll.

DIPLOMA IN PUBLIC HEALTH.—A. MacFarlane.

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—B. Cohen.

DIPLOMA IN PHYSICAL MEDICINE.—A. C. Boyle, M. C. Woodhouse, A. Zinovieff.

#### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Prof. John Morley, F.R.C.S., will deliver the Dr. John Burns Lecture in the Hall of the Faculty (242, St. Vincent Street, Glasgow) on Wednesday, Nov. 19, at 5 p.m. His subject is "Abdominal Pain as an Aid to Diagnosis in Abdominal Disease."

At the annual meeting of the Faculty the following officers were elected for the ensuing year: *President*, Dr. Geoffrey B. Fleming; *Visitor*, Dr. William R. Snodgrass; *Honorary Treasurer*, Mr. Walter W. Galbraith; *Honorary Librarian*, Dr. Archibald L. Goodall; *Representative on General Medical Council*, Mr. Andrew Allison.

#### EPIDEMIOLOGICAL NOTES

##### Poliomyelitis

The decline in notifications continued, and in the week ended Nov. 1 there were 221 (251) cases of poliomyelitis and 22 (29) cases of polio-encephalitis. It now seems probable that incidence will remain at a much higher level than is usual in winter for the remainder of the year, as the decline in prevalence is considerably less steep than was the rise.

In the week ended Oct. 25 no large variation from the preceding week was recorded in individual areas; the largest decline was 11 in Lancashire. The largest returns were those of the county boroughs of Birmingham 9, Salford 7, Manchester 4, Northampton 4, and Croydon 4. Four cases of polio-encephalitis were notified from Gloucestershire, Lydney R.D.

##### Cholera in Egypt

The cholera epidemic which began at El Kurein, a village in Sharkya Province, on Sept. 22 appears to have passed its peak. There are now fewer than 150 deaths and 300 new cases reported daily, as against 400 deaths and 800 cases a few weeks ago.

The present epidemic and the steps taken to control it are reviewed in the *Chronicle of the World Health Organization* (October, p. 141). Energetic measures taken by the Egyptian Government, summarized under 28 headings, and the co-operation of other governments confined the epidemic during its first weeks to a relatively small area in the Nile Delta. Not till Oct. 16 and 17 were cases reported from Kena and Beni Suef (Upper Egypt). The total cases and deaths notified provisionally were:

Week Ending	Cases	Deaths
Sept. 29 .. .. .	523 .. .. .	156 .. .. .
Oct. 6 .. .. .	859 .. .. .	378 .. .. .
Oct. 13 .. .. .	1,303 .. .. .	551 .. .. .
Oct. 20 .. .. .	4,566 .. .. .	2,075 .. .. .
	7,281 .. .. .	3,160 .. .. .

The meeting of the Expert Committee on Quarantine of W.H.O. was held during Oct. 13-16 instead of on Nov. 24 so that problems arising from the cholera epidemic might be discussed. The question of an international certificate to avoid revaccination of a traveller and quarantine restrictions were discussed and a formula agreed upon. The committee were opposed to the issue for persons travelling on urgent business of the wartime "Provisional International Certificate," since this might break down the international system of quarantine protection. Quarantine procedure and the health regulations governing air travel were described by R. H. Barrett in our issue of Nov. 8 (p. 741). A discussion on the epidemiology of cholera is reported elsewhere in this issue (p. 785).

So far 1,400,000 doses of cholera vaccine have been sent from this country to Egypt, most of it manufactured in September and October. The War Office supplied 25,000 ml. to the Egyptian Air Force; 220,000 ml. were sent to G.H.Q., Middle East, and to the Embassy in Cairo for inoculating members of the Forces and British civilians. The balance

was supplied by British firms to the order of the Egyptian Government.

There have been no cases of cholera among British troops in Egypt, but there have been two cases among native African troops under British command.

A report that a case of cholera has been diagnosed at Dubai Air Station on the Persian Gulf has not yet been confirmed.

### Typhoid at Harrow

On Sept. 10 one child fell ill in a Harrow nursery which houses 25 children, all under 5, and all the sons and daughters of European refugees. The nursery is a building not properly adapted for its purpose. On Sept. 20 the child was admitted to hospital, and on Sept. 23 the diagnosis of typhoid fever was confirmed bacteriologically. All admissions to the nursery were stopped, and 13 children and two members of the staff were admitted to hospital for investigation. There were some cases of gastro-enteritis, and altogether 4 cases of typhoid. The source of the infection is believed to have been the mother of a child who was not affected. The mother works at a convalescent home outside Harrow, and Vi-phage type F1 bacilli were found in her case, as in the 4 patients, though in one child only the sixth examination of the stools proved positive.

### Influenza Control in U.S. Army

Vaccination of all U.S. Army personnel began last month, and those entering the service before April, 1948, will receive influenza vaccine along with their initial immunizations. Precautions will be taken to avoid administering influenza vaccine to men with a history of egg allergy. Suspected outbreaks of the disease occurring in a military installation or command are to be reported to the Surgeon General. Laboratory tests will be made in the field on early cases. In addition to the A and B viruses the vaccine contains an A-variant cultured from the distinctive type of influenza that occurred at Fort Monmouth, New Jersey, last year. It is possible that other new strains may be demonstrated this year.

### Discussion of Table

In *England and Wales* an increase was reported in the incidence of dysentery 294, measles 184, scarlet fever 100, and diphtheria 36. There were decreases in the number of notifications of acute pneumonia 49, poliomyelitis 25, paratyphoid fever 13, and cerebrospinal fever 10.

The large rise in the notifications of dysentery was due to an outbreak involving 260 persons in Berkshire, Wallingford R.D. The other large returns for dysentery were Surrey 15, Lancashire 16 (Liverpool C.B. 13), and Yorkshire West Riding 12 (Aireborough U.D. 8).

The only large rises in the incidence of measles were those in Northamptonshire 42, and Yorkshire West Riding 36. Little change occurred in the local incidence of scarlet fever. The only fluctuation of any size was an increase of 44 in Lancashire. The returns for diphtheria were the largest for 30 weeks: the largest increases during the week were Durham 14, and Middlesex 11. Notifications of whooping-cough remained practically unchanged, except for a decrease of 33 in Essex.

In *Scotland* decreases were recorded in the incidence of dysentery 17, diphtheria 15, and cerebrospinal fever 5, while increases were reported for acute primary pneumonia 54, scarlet fever 41, whooping-cough 26, and measles 21. Five further cases of dysentery were notified from the outbreak in Aberdeen county, where 22 cases were reported in the preceding week. The largest return for dysentery during the week was Edinburgh 13. The fall in the incidence of diphtheria was in the Western area. The increase in cases of scarlet fever and acute primary pneumonia was mainly due to the experience of the city of Glasgow. An outbreak of whooping-cough in the city of Dundee accounted for the increase in this disease.

In *Eire* an increase was recorded in the notifications of measles 21 and typhoid fever 14, and a decrease for diarrhoea and enteritis 17. A small rise in the notifications of measles was general throughout the country districts. Of the 17 cases of typhoid fever 6 were notified in Monaghan, Castletown R.D.

In *Northern Ireland* the only variation of any size in the returns of infectious diseases was a decrease of 9 for measles.

### Week Ending November 1

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,529, whooping-cough 1,037, diphtheria 178, measles 2,052, acute pneumonia 502, cerebrospinal fever 39, acute poliomyelitis 221, acute poliomyelitis 22, dysentery 126, paratyphoid 15, and typhoid 4.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 25

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the figures are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire

## Medical News

### National Insurance for the Self-employed

Speaking at the London Rotary Club on Nov. 5, Mr. James Griffiths, Minister of National Insurance, said that in the great majority of cases self-employed men would be coming into national insurance for the first time. The scheme would come into force next July, and, unlike the present unemployment, health, and pensions schemes, would cover everyone, whether working for an employer or not. There would be three classes: (1) those employed under a contract of service—no matter how high their salaries; (2) those gainfully occupied on their own account—the self-employed; and (3) those who are not gainfully occupied in any way. For each class there would be different contributions and benefits. The self-employed included street hawkers, small shop keepers, some independent artisans, many of the professional classes, the heads of businesses, and partners in businesses.

Everyone who was not already insured under either the health, pensions, or unemployment schemes would have to register early next year. The self-employed man would get his contribution card, and when the scheme started in July he would have to stamp that card each week. That weekly stamp was his contribution to the scheme. The Class 2 contributions were 6s. 2d. for a man and 5s. 1d. for a woman each week. Now what would the self-employed man or woman get in return for these contributions? The bare list was: sickness benefit, maternity benefit for his wife, benefit for his widow if he died, guardian's allowance for his children if both parents died, retirement pension in old age, and death grant to help with the funeral expenses. The right to benefit of course depended on his having fulfilled the contribution conditions for each benefit.

### Award for B.C.G. Research

Dr. Joseph Aronson, of the U.S. Bureau of Indian Affairs, has been awarded the Alvarenga prize by the College of Physicians of Philadelphia for his studies on the evaluation of B.C.G. vaccine in the control of tuberculosis. Pedro Francisco da Costa Alvarenga, of Lisbon, an associate fellow of the College, made arrangements in his will for the prize "to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883."

### Fuel Allowance for Tuberculous

The Joint Tuberculosis Council has adopted a resolution asking the Minister of Health to reconsider as a matter of urgency the fuel allowance for the families of tuberculous persons in view of the steep rise in fuel prices since the original scale was fixed.

### Supply of Penicillin

Until recently about 40% of the penicillin produced in this country was exported, but owing to the fact that complaints of shortages have been received exports are now restricted to 30% of production. The amount of penicillin manufactured continues to increase, and was in August 409,000 mega units, as compared with 344,000 in March. Owing to the increasing demand for larger vials, distributors of penicillin have found difficulty in complying with orders from hospitals, and the Ministry of Health requests, therefore, that if only the smaller sizes are available they should be used. Only a small proportion of the penicillin being produced at the moment is white (or crystalline), and, since it is much more expensive than the yellow variety, the Ministry suggests that it should be reserved for intrathecal, ventricular, and subconjunctival administration.

### Storage of Penicillin

The useful life of dry penicillin will probably exceed the expiry date shown on the package if the instructions for storage are complied with. Solutions should be kept in a refrigerator. It is destroyed by acids and alkalis; by metals such as zinc, lead, copper, and aluminium. It is inactivated by the primary alcohols, and by oxidizing agents such as hydrogen peroxide and potassium permanganate. Prolonged boiling destroys it, but it is not affected by heating to 60° or 70° C. for several minutes.

### Bristol's Old People

A conference on the care of old people, arranged by the Bristol and District Divisional Hospitals Council and the Bristol Council of Social Service, was held at Bristol University on Oct. 29. It was resolved that the Council of Social Service should investigate the conditions under which the aged and infirm are living in the city, and what might be done to improve them, and that the Divisional Hospitals Council should discuss with the University the possibility of their undertaking a survey to measure the size of the problem.

### International Pharmacopoeia

Arrangements for an international pharmacopoeia have been made at a Geneva meeting of the World Health Organization of the United Nations, states Dr. C. H. Hampshire, secretary of the Pharmacopoeia Commission.

### Inquiry into Hospital

The Minister of Health has appointed Mr. V. Zachary Cope and Miss M. F. Dykes, S.R.N., to hear the appeal announced in Parliament and reported in this *Journal* on Nov. 8 (p. 752) by the London County Council against the decision of the General Nursing Council to withdraw recognition of St. Leonard's Hospital, Shoreditch, as a nurses' training school. The appeal will be heard on Nov. 18 at the Ministry of Health.

### Public Health in Russia

The public health authorities in Moscow claim that prophylactic measures have rendered typhus extremely rare and smallpox non-existent in Russia. A network of air-ambulance services is being extended even to remote villages, and special attention is being given to the public health problems found in rural districts.

### Wills

Dr. John Thomson MacCurdy, lecturer in psychopathology in the University of Cambridge, left £30,557. Dr. Henry Litherland, formerly of Wigan, left £4,249. Dr. Harold Edwards Flint, for many years a C.M.S. medical missionary, left £54,410. Dr. James Harrison, of North Shields, an alderman of the Tynemouth Council, left £36,968. Dr. Edgar Alfred Field, for many years in practice in Darwen, Lancs, left £494. Dr. Henry Carter, late of Ripon, left £69,997.

## COMING EVENTS

### Ernest Jones Lecture

The British Psycho-Analytical Society invites all members of the medical profession to attend the annual Ernest Jones lecture entitled "Science and Belief" which will be given by kind permission of the Royal Society of Medicine in the Barnes Hall at 1, Wimpole Street, London, W., on Wednesday, Nov. 19, at 8 p.m., by Prof. C. H. Waddington, F.R.S.

### London Association of M.W.F.

The annual general meeting of the London Association of the Medical Women's Federation will be held at the Royal Free Hospital School of Medicine, 8, Hunter Street, London, W.C., to-day (Saturday, Nov. 15), at 3 p.m.

### Royal Microscopical Society

A meeting of the Royal Microscopical Society, which will be devoted to communications on "Electron Microscope Studies of Tissues from High- and Low-breast Cancer Strains of Mice," will be held at B.M.A. House, Tavistock Square, London, W.C., on Wednesday, Nov. 19, at 5 p.m. for 5.30 p.m. Prof. R. D. Passey, M.D., will present a general introduction to the subject and will be followed by Dr. L. Dmochowski, Prof. W. T. Astbury, Sc.D., F.R.S., and Dr. R. Reed.

### Radiological Meetings in London

A meeting of the Therapy Section of the Faculty of Radiologists will be held at the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Friday, Nov. 21, at 2.15 p.m., when there will be a discussion on "Carcinoma of the Vulva," to be opened by Prof. E. Berven (Stockholm), Miss M. C. Tod, and Dr. Frank Ellis. The Radiological Section of the Royal Society of Medicine will meet at 1, Wimpole Street, London, W., on the same day at 8.30 p.m., when Prof. Berven will discuss "Methods and Results in the Radiological Treatment of Malignant Tumours in the Radiumhemmet, Stockholm."

### Royal Sanitary Institute

A sessional meeting of the Royal Sanitary Institute will be held at Dewsbury Town Hall on Saturday, Nov. 22, at 10.15 a.m., when Dr. E. D. Irvine will read a paper on "The Local Authority and the Promotion of Health."

### Middlesex County Medical Society

The next general meeting of the Middlesex County Medical Society will be held at the Royal National Orthopaedic Hospital, Stanmore, on Friday, Nov. 28, when there will be visits to the hospital school, cripples' workshops, and a demonstration of physiotherapeutic apparatus. Short papers will be read by Mr. John A. Cholmeley, medical superintendent of the Hospital's Country Branch, on "The Management of Anterior Poliomyelitis—Early and Late," and by Dr. J. O. F. Davies on "Epidemiology of Anterior Poliomyelitis."

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tuesday, Nov. 18, and Thursday, Nov. 20, 5 p.m. Croonian Lectures by Dr. E. R. Boland: The Administration of Medicine.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—Friday, Nov. 21, 5 p.m. Thomas Vicary Lecture by Dr. I. Harvey Flack: Lawson Tait.

## ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tuesday, Nov. 18, 5.30 p.m. Ballot for election to the Fellowship.

Section of Pathology.—Tuesday, Nov. 18, 8 for 8.30 p.m. Laboratory Meeting at the Royal Army Medical College, Johnslip Street, Millbank, S.W.—Demonstrations by Lieutenant-Colonel J. T. L. Archer: 1. Typhoid Vi Phage; 2. Action of Polyvalent Dysentery Phage Correlated with Agglutination Tests as a Diagnostic Stile; 3. Preservation of Phage by Chemical Agents. Major A. C. Cunliffe: Plate Methods of Demonstrating Bacterial Proteolysis. Lieutenant-Colonel J. A. Manifold: Tropical Anaemias. Lieutenant-Colonel E. W. Hall: The Manufacture of Alcoholized T.A.B. Vaccines. Major K. B. Rogers: An Explanation of Some Discrepancies in "Sedimentation Rates." Major G. B. S. Roberts: Cerebral Tumours and Brain Injuries. Mr. Leach: Malaria Demonstration, Helminthology Demonstration, Visual Aids in Teaching. Major A. R. T. Lundie: "Quiz." Mr. J. H. Grundy: Arthropoda and Other Animals of Medical Importance and Visual Aids in Entomological Teaching.

Section of Dermatology.—Thursday, Nov. 20, 5 p.m. (Cases at 4 p.m.)

Section of Obstetrics.—Friday, Nov. 21, 8 p.m. Short Paper by Prof. James Miller and Prof. Chassar Moir: A Note on the Centenary of the Use of Anaesthesia in Obstetric Practice by J. Y. Simpson. Communications by Dr. J. Dumoulin: Cervical Proliferation in Pregnancy Resembling Carcinoma; Dr. Magnus Haines: Pregnancy and Adenomyoma; Mr. Ian Jackson: Two Cases of Carcinoma of the Bartholin's Glands; Dr. D. Jeffries: A Practical Problem in the Differential Diagnosis of Endometriosis; Dr. T. L. T. Lewis: Pregnancy and Colostomy; Dr. D. S. Matthews: Case of Intestinal Obstruction in Pregnancy; Dr. P. Mitchell: Case of Fibroma and Granulosa-cell Tumours Occurring in the Same Ovary; Mr. John Thurston: A Bacteriological Symphony; and Dr. S. H. Ritterband: Unusual Case of Dermoid Cyst in Puerperium.

Section of Radiology.—Friday, Nov. 21, 8.30 p.m. Paper by Dr. Elis Berven (Stockholm): Methods and Results in the Radiological Treatment of Malignant Tumours in Radiumhemmet.

BRISTOL UNIVERSITY.—At Large Physics Lecture Theatre (Royal Fort), Bristol University, Tuesday, Nov. 18, 8.15 p.m. XXXVI Long Fox Memorial Lecture by Prof. G. Hadfield: Subacute Bacterial Endocarditis. Admission to the lecture is free.

BRITISH INSTITUTE OF PHILOSOPHY.—At Eugenics Theatre, University College, Gower Street, London, W.C., Friday, Nov. 21, 7.30 p.m. Prof. E. A. Milne: The Present Outlook in the Astronomical Universe.

EUGENICS SOCIETY.—At Royal Society's Rooms, Burlington House, Piccadilly, London, W., Tuesday, Nov. 18, 5.30 p.m. G. C. L. Bertram, M.A., Ph.D.: Eugenics, Population Trends, and the World's Resources.

HUNTERIAN SOCIETY.—At Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, London, E.C., Monday, Nov. 17, 8.30 p.m. Motion: That Our Present Diet is Undermining the Health of the Nation. Proposed by Drs. Franklin Bicknell and Kenneth McFadyean; opposed by Sir Jack Drummond and Mr. Magnus Pyke.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Tuesday, Nov. 18, 5 p.m. Dr. M. Sydney Thomson: Parasitic Affections—Animal and Vegetable. Wednesday, Nov. 19, 5 p.m. Dr. C. W. McKenny: X-ray Technique.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Leeds General Infirmary, Friday, Nov. 21, 8.30 p.m. Prof. H. J. Seddon: A History of Scrofula.

LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.—Tuesday, Nov. 18, 5.15 p.m. Dr. Bernard Katz: Transmission of Impulses from Nerve to Muscle.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.—Wednesday, Nov. 19, 3.30 p.m. Mr. L. Z. Cosin: Modern Methods in the Care of the Aged (illustrated).

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Friday, Nov. 21, 8 p.m. Dissertation by Mr. C. W. M. Wilson: Ancient and Modern Views on Water Metabolism.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At London School of Hygiene and Tropical Medicine, Keppel Street, W., Thursday, Nov. 20, 7.30 p.m. Laboratory meeting: Demonstrations.

## POSTGRADUATE DIARY

EDINBURGH ROYAL INFIRMARY.—Thursday, Nov. 20, 4.30 p.m. Honyman Gillespie Lecture by Mr. J. N. J. Hartley: The Story of a Museum

INSTITUTE OF LARYNGOLOGY AND OTOLGY, 330-332, Gray's Inn Road, London, W.C.—Tuesday, Nov. 18, 2.15 p.m. Dr. E. H. R. Harnes: Respiratory Tract in Infectious Diseases.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Nov. 21, 5 p.m. Mr. V. C. Thompson: Mediastinal Tumours.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, W.—Monday, Nov. 17, 5 p.m., Dr. K. V. Ball: Treatment of Prolapse in the Child-bearing Age; Tuesday, Nov. 18, 5 p.m., Prof. R. J. Kellar, Toxaemia of Pregnancy; Wednesday, Nov. 19, 5 p.m., Mr. C. D. Read, Choice of Treatment in Carcinoma of the Cervix; Thursday, Nov. 20, 5 p.m., Prof. H. Sheehan, Pathology of Obstetric Shock; Friday, Nov. 21, 5 p.m., Dr. G. Marshall, Survey of Pregnancy Associated with Pulmonary Tuberculosis. Admission to lectures by ticket only. Fees: 10 lectures, £2 2s.; single lecture, 10s. 6d.

## APPOINTMENTS

Dr. D. Campbell has been elected vice-chairman of the St. Helens Executive Council and, for the thirteenth consecutive year, chairman of the St. Helens (National Health) Insurance Committee.

CANT, WILLIAM H. P., M.B., B.S., M.R.C.P., Physician to Out-patients Children's Hospital, Birmingham.

CONNOLLY, EUGENE V., M.B., B.Ch., D.P.H., D.C.H., Medical Officer Health, Borough of Oldbury, Worcestershire.

LONDON COUNTY COUNCIL.—The following appointments have been made to the Council's mental health services at the hospitals indicated in parentheses: Senior Registrar, F. Kraupl, M.D., D.P.M., and J. H. Rey, M.B., B.S. (Maudsley Assistant Pathologist, C. K. McDonald, M.B., Ch.B., D.P.H. (Epsom Pathology Laboratory); Assistant Physician, F. Post, M.B., B.S., M.R.C.P., D.P. (Maudsley). The following appointments have been made in the London School Health Service: Assistant Medical Officer, C. B. Grimaldi, B.M., B.Ch.; Part-time Consultant Psychiatrist, W. Lindesay Neustatter, M.D., M.R.C.P.

MIDDLESEX HOSPITAL, W.—Professional Medical Unit: First Assistant, J. Paulley, M.D., M.R.C.P.; Second Assistant, R. Semple, M.B., Ch.B., M.R.C. Professional Surgical Unit: First Assistant, R. S. Lawrie, M.D., F.R.C. Second Assistant, L. P. Le Quesne, B.M., B.Ch., F.R.C.S. Senior Assistant Department of Thoracic Surgery, G. C. L. Pile, M.S., F.R.C.S.

PHILPS, A. SEYMOUR, F.R.C.S., Assistant Ophthalmic Surgeon, St. Bartholomew's Hospital, London, E.C.

ROTH, M., M.D., M.R.C.P., Senior Psychiatrist, Crichton Royal Mental Hospital, Dumfries.

WHELTON, W. F., M.Ch., N.U.I., F.R.C.S. (Ed.), Honorary Surgeon to Eye Department, North Infirmary, Cork.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

DERRETT.—On Oct. 16, 1947, at Fernwood House, to Pearl (née Penith), M.B.S., wife of Rev. L. J. Derritt, a son.

GERRIE.—On Nov. 2, 1947, at Rubislaw Nursing Home, Aberdeen, to Mr. Mrs. John Gerrie, twins—a son and daughter.

McGOWAN.—On Nov. 4, 1947, at St. Brenda's Nursing Home, Bristol, Dr. Rosalind S. McGowan (née Barclay), wife of Dr. G. K. McGowan, daughter.

## MARRIAGE

DENT—TEMPLETON.—On Nov. 1, 1947, at Aberdeen, Ronald V. Dent, M.M.R.C.P., to Maty A. Templeton, M.B.

## DEATHS

BARNES.—On Nov. 1, 1947, at Greentree, Collyton, Devon, Henry John Barnes, M.R.C.S., Lieutenant-Colonel, R.A.M.C. (retired).

BIRKETT.—On Oct. 28, 1947, at The Ghyll, Grange-over-Sands, George Thomas Birkett, L.R.C.P., L.R.C.S. (Ed.).

BRAMWELL.—On Oct. 30, 1947, at Richmond, Yorkshire, Dan Cunningham Byrom Bramwell, M.B., Ch.B., aged 30.

BURGHARD.—On Oct. 31, 1947, at 7, Causewayside, Cambridge, Frédéric Henri Burghard, C.B., M.D., F.R.C.S., Colonel, R.A.M.C., aged 83.

DOWDING.—On Nov. 7, 1947, at 17, Westex Gardens, London, N.W., Frederick Charles Dowding, M.R.C.S., late Major, R.A.M.C., aged 73.

DURRANT.—On Oct. 30, 1947, at Walmer, Norbert Sidney Durrant, L.R.C.P. (A). Goble.—On Nov. 1, 1947, at Chidham Cottage, Hayling Island, First George Goble, M.R.C.S., L.R.C.P., Surgeon-Captain, R.N. (retired).

GREEN.—On Oct. 31, 1947, Edgar Francis Stephen Green, M.B., Ch.B. GREGORY.—On Oct. 31, 1947, in Woodleigh, Bramhall, Cheshire, Arnold Gregory, M.R.C.S., L.R.C.P., aged 68.

HAIO.—On Nov. 2, 1947, at Crieff, William Haio, T.D., D.S.O., M.B., C.M. HOWKINS.—On Oct. 30, 1947, Cyril Henry Howkins, C.B.E., D.S.O., M.R.C.L.R.C.P.

HUNTER.—On Nov. 7, 1947, at Thirladene, Bridge of Allan, Walter King Hunter, M.D., D.Sc., LL.D., Emeritus Professor of Medicine, Glasgow University.

KAUNTZE.—On Nov. 4, 1947, at Woking, William Henry Kauntze, C.M. M.B.E., M.D., F.R.C.P.

McCULLOCH.—On Oct. 26, 1947, at South Park, Hexham, Colin McCulloch, L.R.C.P., L.R.C.S. (Ed.), L.R.F.P.S. Glas.

MALLETT.—On Oct. 29, 1947, at The Gables, Minchinhampton, Street, G. Sir Frederic Rowland Mallett, M.D., aged 78.

NEWTON.—On Oct. 29, 1947, at South Broomhill, Morpeith, Duncan G. Newton, F.R.C.S. (Ed.).

ROBERTS.—On Nov. 7, 1947, at 28, Radnor Park Road, Folkestone, H. Trehanne Llewellyn Roberts, L.R.C.P., L.R.C.S. (Ed.), aged 69.

STRICKLAND.—On Nov. 3, 1947, at Roqueville, Mont Cantel, St. Helier, J. Cyril Strickland, M.D., aged 66.

VOST.—On Nov. 2, 1947, at 22, Manor Way, South Croydon, William V. M.B., C.M., Lieutenant-Colonel, I.M.S. (retired).

WHITE.—On Nov. 9, 1947, John Richard White, L.R.C.P., L.R.C.S. (Ed.), aged 71.

WILLIAMS.—On Oct. 29, 1947, at Mount Auburn, Killybeg, Herbert Arthur Williams, D.S.O., M.B., B.Ch., Lieutenant-Colonel, I.M.S. (retired).

YOUNG.—On Nov. 5, 1947, at Edinburgh, William Allan Young, D.S.O., M.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Prevention of Colds

**Q.**—Patients often ask about the efficacy of inoculations to prevent colds. Can you recommend any preparation suitable for administration to a number of people?

**A.**—Various controlled trials in the use of "anti-catarhal" stock bacterial vaccines for the prevention of the common cold have shown that such vaccines are not to be relied on as a prophylactic measure. It is now generally accepted that the common cold is due to a virus or a number of viruses, and a bacterial vaccine containing organisms like the pneumococcus, streptococcus, and influenza bacillus could obviously not prevent the primary attack. Whether such a vaccine could prevent or modify secondary bacterial infection due to these organisms is also debatable, since there is great variety in the types of pneumococcus and streptococcus which might be involved. However, practitioners claim that they have seen good effects from the prophylactic use of anti-catarhal vaccines which are available from a number of commercial firms.

### Aspirin and Cerebral Congestion

**Q.**—Is there any evidence to show that aspirin and related drugs may increase cerebral congestion? Has any simple correlation been established between increased intracranial and intraocular tension, and is there any known correlation between variations of these pressures and changes in barometric pressure, is a matter of normal physiology?

**A.**—Aspirin and related drugs do not increase cerebral congestion. There is no simple correlation between intracranial and intraocular tension, nor is there any known connexion between barometric and intracranial pressures.

### Mortality Statistics of Pneumonia

**Q.**—Could you either give me statistics showing the mortality from lobar pneumonia and bronchopneumonia in children under 2 years before and after the introduction of antibiotics, or let me know where I might obtain such information?

**A.**—Mortality statistics are published in quinquennial age groups, and it is not possible to obtain figures for children under 2 years of age. Deaths from lobar pneumonia and bronchopneumonia in the following age groups—under 1, 1-5, 5-10, 0-15, etc.—are published in Table 21 of the Registrar-General's Statistical Review. The continuity of these statistics has been broken by a change in classification in 1940, when, in the case of multiple causes of death, the physician's choice was accepted in place of set procedure. The Registrar-General has given a factor to convert to the recent classification.

### Mixed Feeding for Babies

**Q.**—Is it now considered wise to introduce patent cereals, craped carrot, sieved vegetables, and purées, including prune purée, with visible roughage, into National dried milk or other milk foods for babies under 8 months? Unchanged particles of these extra foods can be recognized in the stools of babies, who are often restless and sleep badly.

**A.**—Mixed feeding can safely be started long before 8 months of age; some authorities suggest about 4 months, and certainly most of the items mentioned could be started at 6 months. They should not be put "into" the milk feeds used (except cereals made with milk) but gradually utilized as steps towards a full mixed diet. The stools will, of course, change in character when articles other than milk are given, and cellulose material will appear more or less unchanged. But this is a normal state of affairs, and possibly teething is a more likely explanation of the restlessness and poor sleep of babies at this age.

### Trilene in Obstetrics

**Q.**—What are the latest views on trilene in obstetrical practice?

**A.**—Trilene administered with a well-constructed inhaler gives very satisfactory results as an analgesic in obstetrical practice. It must, however, be administered under the supervision of a medical practitioner; midwives are not allowed to use it on their own. The inhaler, of which there are now several patterns, limits the strength of trilene vapour inhaled, so that no more than analgesia is produced. Trilene should never be used in a carbon-dioxide absorber, for in the presence of alkali very toxic breakdown products may be formed. The simple inhalers used for obstetric analgesia do not employ soda lime and therefore this danger does not exist.

### Removal of Superfluous Hair

**Q.**—What would you recommend to young women for removing hairs on the chin and upper lip? Are there improvements on electrolysis, removal by wax, or simply pulling them out? If removed by electrolysis do the hairs recur? If hairs are repeatedly pulled out, do they become stiff and short like a man's beard? Is the belief fallacious that the pulling out of hairs causes an increased number to grow?

**A.**—If the patient does not approve of the electric razor, which is probably the best treatment, the other measures enumerated are satisfactory. None of these measures increases the number or calibre of the hairs. There is no new treatment for simple hirsuties.

### D.D.T. as an Anthelmintic

**Q.**—The usual anthelmintics (santonin, diphenan, and gentian violet) do not always cure and are valueless in preventing reinfection. It occurred to me that in the latter case D.D.T. might be more satisfactory than smearing the anus with ointment—if the theory is correct that the female worm emerges at night to lay eggs. The worm is certainly susceptible to D.D.T., as I proved by exposing a faecal mass swarming with worms to D.D.T. solution: all were killed. I suggest powdering the anal fold at night with D.D.T., which I have carried out without any irritant effect on the skin. The next step is obviously the internal use of D.D.T., but I hesitate to carry this out experimentally in children. Are there any findings available regarding the toxicity of D.D.T.? Has it been used for this purpose, and, if so, what dosage is recommended?

**A.**—The questioner does not state what parasite he is attempting to eradicate, but it seems likely that *Enterobius vermicularis* is concerned. There do not appear to be any data regarding the toxicity of D.D.T. to nematodes. One would hesitate to conclude that powdered D.D.T. was toxic to worms because they were killed by a solution of the chemical, unless it had been shown that the solvent itself was innocuous. Certainly by analogy with insecticidal work D.D.T. is unlikely to affect the eggs. Powdering the anal fold with D.D.T., suitably diluted, is unlikely to be harmful, though perhaps of doubtful efficacy. D.D.T. should not be used internally. A good review of the toxicity of D.D.T., by F. M. G. Stammers and F. G. S. Whitfield, will be found in the *Bulletin of Entomological Research* (1947, 38, 1).

### Food Value of Gelatin

**Q.**—Am I right in thinking that gelatin, though absorbed, has no food value, and that consequently bone broth is not nutritious?

**A.**—Gelatin, a degradation product of the animal protein collage, is inadequate by itself as a source of the nine or ten amino-acids essential for the normal nitrogen metabolism of man and other animals. It can, however, exercise a "sparing" action on the use of biologically adequate protein, for it is a fair source of arginine and lysine, besides being rich in certain non-essential amino-acids—namely, glycine, proline, and oxyproline. Its content of essential amino-acids, moreover, is such that it can show "supplementary" action with certain vegetable proteins also not able by themselves to satisfy nitrogen requirements.

## Onychia

**Q.**—In a case of onychia, removal of the finger-nail with antiseptic treatment of the nail-bed and several courses of x-ray therapy has been ineffective. What further treatment do you suggest?

**A.**—It is presumed that coecal or monilial or ringworm infection of nail, nail-bed, and perionychial spaces is implied by this question. A general overhaul of the patient and of his skin for other sites of disease or infection may be fruitful. For coecal infections general treatment with penicillin and sulphonamides is indicated, and locally dry heat, short-wave diathermy, or fractional doses (120 r.) of unfiltered x rays and painting with spirituous solutions of the dyes. Lotions, ointments, and water should be avoided. For fungous disease removal of the nail and subsequent irradiation with unfiltered x rays in fractional dosage at monthly intervals offers most hope, provided there is continuous treatment with effective fungicides. Alternating the following in weekly periods is suggested:

R Ung. dithranol. B.P.

R Ung. iodi denigrescens B.P.

R

Benzoic acid	..	..	..	..	24 gr. (1.6 g.)
Salicylic acid	..	..	..	..	30 gr. (2 g.)
Soft paraffin	..	..	..	..	1 dr. (4 g.)
Coconut oil	..	..	..	..	to 1 oz. (31 g.)

Make into an ointment

R

Mercury perchloride	..	..	..	..	1/2 %
Brilliant green	..	..	..	..	1/2 %
Industrial spirit	..	..	..	..	to 100 %

Make into a paint

## Loss of Finger

**Q.**—A man aged 25, a handyman-mechanic, recently had the distal and middle phalanges of the middle finger of the right hand removed at operation. He has a satisfactory stump with good movement. The other fingers are normal. What is his disability, and is he entitled to claim workmen's compensation? Could you recommend a book dealing with this subject?

**A.**—Loss of the middle and distal phalanges of the right middle finger would constitute a permanent partial disability of the order of approximately 5 to 8% as compared with a normal working man. Disability would be increased by undue tenderness of the stump or by its "getting in his way" at work. If the loss was sustained as the result of an accident occurring in the course of his work he should be entitled to a claim for workmen's compensation. An authoritative account of industrial medicine, disability, and compensation is contained in *Occupational Diseases*, by R. T. Johnstone (W. B. Saunders Company).

## Resection of Small Intestine

**Q.**—What is the present surgical opinion as to the largest amount of small intestine that can safely be removed, leaving reasonably normal digestive and absorptive functions? What is the best diet once the patient has got over the operation?

**A.**—Without knowing more details of the particular operation it is not easy to answer this question categorically. Most surgeons would probably agree that the loss of more than 10 to 12 feet (3 to 3.6 m.) of small intestine makes a reasonable post-operative metabolic life difficult; but this statement must be qualified to some extent by the portion of small gut concerned, massive excisions of jejunum being more detrimental than those of ileum. During the war a number of cases were reported where greater lengths than those quoted above were removed and the patient survived. The problem of feeding in such cases is undoubtedly a difficult one; they are relatively so few in number that it cannot be said any general agreement has been reached on the quantity of or form in which amino-acids, predigested fats, and vitamins (all of which are necessary) should be supplied. Some help may be obtained from a recent article by H. W. Meyer on "Recovery Following Extensive Resection of Small and Large Intestine" (*Arch. Surg.*, 1946, 53, 298).

## NOTES AND COMMENTS

**Bates on Better Eyesight.**—Dr. RONALD KERR (London, N.W.) writes: As one who has in the past made a serious effort to practice Bates's eye treatment, may I comment on the answer on this subject (Nov. 1, p. 717)? I agree entirely that it is not possible to alter refractive errors in adults. In cases of the larger errors with defective vision, Bates's treatment often enables patients to see better without their glasses than they did before, but normal vision is not attained, and the improvement is presumably due to an increased ability to interpret blurred images, and is not due to any decrease in the refractive error. Though Bates's claim is quite untenable, that once "strain is relieved" refractive errors disappear, nevertheless he did produce something of value, and that is the idea that there is a right and a wrong way of using the eyes. The right way of looking, according to Bates, is (1) to avoid making effort, peering, staring, and straining to see; (2) to pay attention only to that part of the image which falls on the macula; and (3), which is a corollary of (2), to shift the attention rapidly about from point to point of the object regarded.

Lack of space forbids further discussion of this idea, but I should like to record that I believe it is physiologically sound, that bad habits of staring, not blinking, and not "shifting" can and do produce symptoms of ocular discomfort, and that the benefit which patients often get from being taught good habits is not entirely due to suggestion. In cases where patients complain of discomfort rather than defective vision there appear to be three factors concerned: (1) the refractive error; (2) the presence or absence of adequate convergence power; (3) the way in which the eyes are used. Oculists have paid much attention to refractive errors, and are now beginning to realize the importance of convergence deficiency. They have not yet recognized the existence of bad habits. In these cases treatment of convergence and/or the inculcation of good habits usually relieve the symptoms completely. The small refractive error remains, but by itself produces no symptoms, and can be ignored. These are the cases in which the Bates practitioners get their undoubted successes. Patients are enabled, without recurrence of symptoms, to discard the glasses which have been unnecessarily prescribed by those who are not familiar with the alternative treatment.

In cases of presbyopia and moderate degrees of hypermetropia the need for glasses can be postponed by compelling the ciliary muscle to go on working. If the convergence is good and the habits right, it can be done without undue symptoms with the aid of some of the Bates "exercises." Whether it is worth the effort is another matter, but to show what can be done I will cite the case of a Bates practitioner whom I have refracted. She has no appreciable error, and at the age of 60 has never had glasses. She can read ordinary print comfortably in a good light, and in fact read a great deal, though poor print in a poor light defeats her.

**Confidence Trick.**—A consultant in Liverpool received a letter from a Mr. Andrew M. Hadjipavlis, of Famagusta, Cyprus, who asked a number of questions about a patient said to have syphilis. The consultant replied that he could give no advice on a patient whom he had not seen and who was under the care of another doctor. He quite properly went on to make some general remarks about the treatment of syphilis. He then received a letter from Mr. Hadjipavlis, who apologized for not informing the consultant in the first place that he was "a Press Correspondent, and that there was no any patient in reality." Mr. Hadjipavlis said that although the consultant's letter was very brief there was something in it which he might use in his papers. "My intention," he added, "was to run a campaign in the local and Middle East newspapers toward the treatment which is being carried out by Government Hospitals." We are indebted to the consultant in question and the Medical Defence Union for allowing us to put these details on record so that they may serve as a warning to other practitioners.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 15 1947

## STATE MEDICINE IN EIRE

The Department of Health of the Government of Eire has issued a White Paper<sup>1</sup> entitled "Outline of Proposals for the Improvement of the Health Services." It states that the proposals have been approved in principle by the Government and are in accordance with the undertakings given by Mr. De Valera to Parliament. They are put forward for public information and discussion. The first reaction of the *Journal of the Medical Association of Eire* is that, although the Government has refrained from introducing a universal free medical service, the proposals are too much in the direction of State paternalism.

### Present Health Services

The White Paper begins by tracing the evolution of health services from the setting up of local health authorities, called Boards of Health, in 1818, to the establishment last year of a Government Department under a Minister of Health. It then proceeds to a review of the present health services available. The local authority services consist of a general-practitioner or dispensary service administered by public-assistance authorities; county, district, and fever hospitals also administered mainly by such authorities; a mental-hospitals service; and the usual public-health organization for the control of infectious disease, the school medical service, and anti-tuberculosis measures. Medical assistance provided by the public-assistance authorities employs 646 general practitioners, and the service, which is free to all those who cannot afford to provide for such medical care out of their own resources, is regarded as covering about one-third of the population. Participation in the benefits of this service is subject to a means test, though this is not rigidly applied.

With regard to the services other than those of the local authorities, including the work carried on by voluntary hospitals and other voluntary agencies, it is stated in the White Paper that the sphere of voluntary treatment and private practice is being progressively invaded by the official services. Voluntary hospitals and nursing associations are being increasingly associated with schemes which are subject to official supervision. Many private practitioners seek part-time employment under local authorities to supplement their income from private practice. Thus the scope of voluntary and private activity tends to be circumscribed by the normal growth of public services. It should be explained that in Eire general-practitioner treatment for insured persons is not one of the statutory benefits of the Insurance Acts, though other forms of medical care are provided through a scheme of additional benefits. At the same time the White Paper acknowledges many gaps and shortcomings in the public services and points out the need for a new approach to health problems in view of the present high mortality in the younger age groups of the population and the economic waste involved in illness and disability.

### The Health Act, 1947

This year a new Health Act has been passed in Eire. Its aim is not to deal with the question of a comprehensive State service, which may come later, but to simplify and improve the present preventive measures, such as the infectious-diseases service and the supervision and standardization of food supplies. The most contentious part of the measure is the establishment of a comprehensive health service for mothers and children. The Act provides that a health authority—that is, a council of a county or a corporation of a county borough—

shall make arrangements for safeguarding the health of women in respect of motherhood and generally shall provide attendance for children, a child being defined for the purposes of the Act as a person who is less than 16 years of age. Apparently this service is to be entirely free irrespective of income level. The primary responsibility for inspection and treatment will rest with the district medical officer in each dispensary district.

It is understood that the details of the operation of this service will not be finally settled until representatives of the medical profession and other interested bodies have been consulted. But the opinion of the medical profession, as given in the source quoted at the beginning of this article, is that the arrangement appears to deny the principle of free choice. Parents should have the right to decide who is the most suitable doctor to have supervision and control of the health of their children. Why should the principle of payment for private attendance in this sphere be abolished? The dispensary health services were originally set up for the poor, who were unfairly and invidiously denied free choice of doctor if a member of their household became ill, and now it appears that the arrangement is being enlarged to include more and more of the population; and even the service of the voluntary hospitals is threatened by the same sort of regimentation.

### Proposals for a Comprehensive Service

The universal mother-and-child service under the new Health Act is only a foretaste of further proposals, an outline of which is given in the final section of the White Paper. These are proposals for a reorganization and extension of health services generally. It is admitted that from the point of view of affording optimum benefit the simplest solution of the problem of a comprehensive medical service and its finance would be to make the service available to all citizens free of charge. The Government, however, stops short of this and acknowledges that many persons who are able to meet the cost of providing medical care for themselves would prefer not to participate in the scheme, and that some members of the medical profession would prefer to remain independent. "Generally, therefore, it appears desirable in existing circumstances that a certain upper-income field should be left for private practice."

It is considered imperative, however, that a full range of medical care should be made available to a very greatly extended proportion of the population. Those who choose to have a private general practitioner to attend them will be responsible for his fee, but the practitioner will be able to obtain for them free access to the specialist, hospital, and other facilities provided under the scheme.

The points in the scheme recommended for discussion are as follows:

- (1) Local health administration to be conducted in each county or larger unit by a specially constituted local health authority.
- (2) Existing health services to be extended and supplemented and the improved services to be co-ordinated.
- (3) All personal services dealing with prevention and treatment of infectious disease and the mother-and-child service to be provided free of direct charge to individuals of all classes.
- (4) The entire range of medical care under the scheme to be made available to all recipients of home assistance, unemployment assistance, pensions under social-assistance schemes, and similar classes of the population.
- (5) General-practitioner service by district medical officers, together with institutional care and specialist advice and treatment, to be available free in cases in which the annual income does not exceed £250.

<sup>1</sup>The Stationery Office, Dublin. 1s.

(6) Institutional care and specialist advice and treatment (but not general-practitioner service) to be available in cases where the annual income exceeds £250 but does not exceed £500.

### County and Regional Administration

It is proposed to develop the health services in two main sections. The county service will be based on the district medical officer and administered under the control of the local health council. Each county will be divided into a number of district health units based on available personnel and organization and built up gradually to optimum requirements. The old dispensary districts would be adopted first, but more suitable boundaries might presently be determined. The normal health unit would provide for a health clinic with doctor, nurse, and midwife. The district medical officers will find their duties altered and enlarged, and an increase in their remuneration will be necessary. Private practice will be allowed, but the prior claim of the public service on the medical officer's time must be recognized. Private practitioners outside the service may avail themselves of the specialist, hospital, and laboratory facilities provided under the scheme on behalf of their patients who are entitled to such services free, and higher-income patients may also participate in them, through their general practitioner, on payment of appropriate fees. The number of persons for whom a district medical officer is responsible will be so adjusted as to take account of his extended duties, which will include a general-practitioner service for eligible classes, a maternity service, and such preventive work as immunization measures and case-finding of infectious diseases.

County and district hospitals will provide the general medical, surgical, and obstetrical service for each local area, but the specialist and regional hospital services will be on a wide basis and will be generally associated with the university medical schools. As conditions permit, regional hospitals will be provided at Cork and Galway, and an auxiliary regional hospital at Limerick; while at Dublin, it is hoped, with the co-operation of the teaching and voluntary hospitals, special co-ordinated arrangements for regional hospital services will be made. It is expected that there will be, on a regional basis, sanatoria, laboratory services, a public-health institute, facilities for the early diagnosis of cancer, and centres for the investigation and treatment of rheumatism. For Dublin city and county a unified health service is proposed which will link together the health services at present carried on by the health authorities, the private-practitioner groups, and the voluntary hospitals and other agencies. Health clinics are projected to provide a general-practitioner service and the maternity-and-child service. Each clinic will have the daily services up to an agreed hour in the afternoon of a district medical officer, and, with an assistant medical staff, a round-the-clock service will be given. Larger consultative centres for difficult cases are also envisaged. The local health councils and regional health boards will have a majority of direct representatives of the authorities, but there will be co-optation of other persons knowledgeable and interested. The cost of the service will be met equally from the rates and from State grants. It is expected that at the end of the first ten-year period it will amount to £9,000,000 a year.

The comment of the *Journal of the Medical Association of Eire* is that there is neither rhyme nor reason in making the maternity and child health services free to all.

"We fear that in its anxiety to expand the public health services the Government is attempting to train a generation accustomed to State paternalism from its very cradle. The purpose should be the health of the population, not the policy of nationalization and regimentation."

But in Eire, as in this country, the scheme cannot be fully implemented for some years to come because of the demands of the building programme. To meet the capital cost of institutional construction the authorities are hoping for an increase in the annual amounts derived from sweepstakes.

A circular from the Ministry of Health to port health authorities and riparian authorities reminds them of their powers under the Public Health (Imported Food) Regulations, 1937, to appoint, with the consent of the Minister, an assistant officer to work under the direction of the medical officer of health.

## THE DAIN FUND

### REPORT OF THE TRUSTEES

During the past year the work of the Dain Fund has been continued and increased. Many inquiries have been received and advice has been given and in certain cases assistance has been arranged through other funds, such as the Medical Welfare Relief Fund and the Royal Medical Benevolent Fund and Royal Medical Foundation of Epsom College.

Five new applications have been considered by the Trustees and in each case it has been possible to give financial help. In so many cases, the same story is told: the prolonged illness or sudden death of the practitioner leaves his widow in great financial difficulties.

*Case 1.*—The sudden death of the practitioner forced his widow to apply for help for her daughter, who had one year to complete at college. Although the mother was trying to obtain employment at a school or hotel, the girl's career would have had to be abandoned unless help was forthcoming. In this case the Trustees decided on a grant of £195, of which £45 has been paid.

*Case 2.*—Application was made by the mother of a fifth-year medical student for assistance to enable her son to complete his training. For four years since the death of his father, a general practitioner, the applicant had struggled to maintain the boy, and during the last year some help had been given by other bodies. A sum of £50 was required to meet the financial position until the date of qualification in 1948. The Trustees gladly granted this sum.

*Case 3.*—A medical practitioner, who had been ill for many months, applied for assistance in the education of his son aged 11 years. The applicant died suddenly and the application was renewed by his widow. A sum of £45 was required for school fees. The local panel committee made a grant of £25, the Trustees of the Dain Fund agreeing to make up the balance of £20. The Trustees also intimated that they would be prepared to consider a further application for the continuation of the grant in 1948 should it be necessary.

*Case 4.*—In 1941 a medical practitioner died leaving his widow with four children. The widow joined the A.T.S. and by a great effort has been able to provide for the three elder children. The youngest child was 12 at the date of the application for £100. By arrangement with the local panel committee, which most generously offered to help, this sum was divided—£50 being given by the panel committee and £50 by the Dain Fund. The Trustees have recently reconsidered this case and a further grant of £50 has been made for the school year beginning September, 1947.

*Case 5.*—An application was received from the wife of a medical practitioner who is now unable to work owing to illness for financial assistance for her son, a medical student who has passed his 1st M.B. and is about to enter a London medical school. The application was for a considerable sum of money to cover all expenses. The Trustees felt unable to provide the whole sum; a grant of £40, however, was allowed subject to his acceptance by the medical school—the grant to be continued if necessary during his training, subject to a satisfactory report from the dean of the medical school.

In addition to the cases listed above the Trustees have been able to continue assistance to three cases who have received help in previous years. These three children have all done well. To one, a girl, a grant of £50 has been given for two years (1946 and 1947). She has taken her School Certificate and intends to make medicine her career. The second case is of a boy who has been helped by a grant of £50 per annum for five years during his school career. He has done well, passing London matriculation and gaining his Higher School Certificate. He is now hoping to obtain admission to a medical school if not called up for military service. The third case of this group is of interest. The Trustees have allowed £100 per annum to the son of a deceased doctor to assist in the fees for his dental training, subject to satisfactory reports from the dean. Up to the present time this boy's progress and work have been very satisfactory.

From the above report it will be seen that £565 has been given in grants of varying sums during the year (October, 1946–September, 1947). This has been possible by the continued support of both individual members of the profession and panel committees. Following the successful negotiations with regard to the capitation fee, the Bristol Panel Committee in a letter to the *British Medical Journal*, which was also sent to all panel committees, suggested that panel committees might wish to express their satisfaction by giving financial support to the Dain Fund. A number of committees responded to this suggestion. The Trustees, in considering the financial position of the Fund

agreed that in future, of all sums received for the Dain Fund, 50% should be invested, the remainder being placed in the current account.

The Trustees would like to take this opportunity of thanking all who have been so generous in the past. They are satisfied that the cases quoted show beyond doubt the need for the Fund, and they must ensure that this support will be continued and extended in order that in the future no suitable application for assistance need be refused for lack of funds.

September, 1947.

## THE UNATTENDED TELEPHONE

The Association, conscious of the difficulties which doctors experience in securing adequate domestic help, has for some time been exploring various facilities that are claimed to solve the problem of the unattended telephone. Members will therefore be interested to learn of the various services that have been brought to the notice of the Association. The facilities in question fall into two main groups—namely, direct recording instruments and message-taking bureaux; the former being equally effective in any part of the country, the latter, because of possible delays in the trunk- and toll-telephone systems, being effective only in the immediate area of the bureau.

### Direct Recording Apparatus

A description of the robot telephone has already been published in the *Supplement* (Aug. 23, p. 57), and it is sufficient to add that this apparatus was demonstrated at a recent meeting of the General Practice Committee, when the impression was gained that it is a very effective message recorder, amply justifying the claims made on its behalf.

As with all inventions, the initial cost of putting the apparatus on the market is not inconsiderable. The manufacturers have indicated, therefore, that in the first instance they would be prepared to manufacture 100 of the instruments if they could be assured of this number of purchasers. Up to the present time only some 30 to 40 practitioners have signified their interest in the apparatus, and the Secretary would be pleased to hear of any other interested practitioners. As soon as the list of probable purchasers reaches 100 it is proposed to pass the names to the manufacturers, who will then make direct contact with the practitioners concerned. The price of the instrument is £80, plus a small charge for installation.

A very compact and portable dictaphone, manufactured by Miles Aircraft, Ltd., is also available. While this instrument does not solve the problem of the unattended telephone, it is possible that it might be adapted later for the purpose. Apart from this, the ease with which this dictaphone can be carried around makes it an ideal instrument for the busy practitioner who finds it difficult to set aside the time for dictating correspondence.

### Message-taking Bureaux

There are in the London area a number of bureaux which claim to offer an efficient service for the reception and re-transmission of telephone messages. Although each of the organizations mentioned below differs in detail, the main principle is the same. The doctor notifies his patients that, if they are unable to obtain a reply to a telephone-call to his house or surgery, they should ring an alternative number—i.e., the number of the service. Messages will there be recorded and relayed back to the doctor at his request. Each of the organizations provides a 24-hour service, and in cases where the practitioner contemplates being absent from his surgery for a period of not less than 24 hours the G.P.O. will, at his request, automatically intercept calls and pass them to the alternative number. (Presumably this applies only in the case of manual exchanges.)

Interested members are advised to address their individual inquiries to the organizations concerned, from whom full details are available; and it is suggested that they should at the same time inquire whether the service has obtained from the Postmaster General a licence to operate.

Finders, Ltd., 77, Dean Street, W.1. Tel., Gerard 9050 (20 lines). Subscription (special service) £12 12s. per annum, plus the cost of calls incurred on the subscriber's behalf.

Per-Call Service, Ltd., 387, London Road, Mitcham. Tel., Balham 3331 (5 lines). Subscription £5 5s. per annum, cover-

ing 150 1d. calls within the Metropolitan area or their equivalent in trunk or toll calls.

Telasco, Ltd., 20, Queen Street, W.1. Tel., Mayfair 5401. Subscription £18 18s. per annum, plus the cost of trunk and toll calls incurred, and 1s. for each four local calls over 30 per month.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils.*—Barnsley, Gateshead.

*Metropolitan Borough Councils.*—Fulham, Hackney, Poplar.

*Non-County Borough Councils.*—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

*Urban District Councils.*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs.*—Motherwell and Wishaw.

## Correspondence

### Working Hours in the N.H.S.

SIR,—My friend Stanley Turner (Oct. 18, p. 92) has done the profession a useful service in pointing out the probability that the normal work of the doctor in the new Health Service will be enormously increased. When the insured person discovers, as he must do before long, that he is in fact paying, through the compulsory insurance, a levy at the rate of from 12s. to ultimately 17s. a week per person, he will undoubtedly and rightly do his best to get his money's worth by increased demands upon the doctor.

I have endeavoured, without success, to get a reply from the Minister to Parliamentary questions asking him for estimates as to the number of registered medical practitioners which his Act will require. Similar estimates as regards teachers were readily forthcoming from the Minister of Education, but not from the Minister of Health. But there are some pointers which may make possible an approximate estimate of this requirement. A 24-hour medical service is promised by the Act to include specialist and institutional service as well as the general practitioner service supplied by the old N.H.I. Act. The Socialist Medical Association (S.M.A.) has justifiably claimed that its advice has been largely instrumental in moulding the Act. The 5-day 40-hour week is an essential plank in the Socialist programme, and concrete proposals were actually made by the S.M.A. that the medical day of 24 hours should be worked by three 8-hour shifts. It is to be noted that this does not meet the week-end demand, and in the experiment in New Zealand, where the 5-day 40-hour week is generally imposed, it has been observed that "it is extremely difficult for the public to secure medical attendance in New Zealand over the week-end."

Turner mentions that there are 70,000 names on the *Medical Register*, but an authoritative estimate places the number of doctors in *active practice* at approximately 50,000. With a day divided into three shifts, and taking into consideration the increased demand on the doctors' services, I submit that an estimate which places the total medical personnel required by the Act at three times the present number in active practice errs on the side of moderation. If the Minister succeeds in roping in the whole existing body in active practice, he will on this basis still need a further 100,000 doctors to implement the promises of the Act.

My estimate that the present active strength of the medical profession would have to be trebled to meet the needs of the Act receives an independent corroboration. Lord Teviot, who was for two and a half years chairman of the Inter-Departmental Committee on Dentistry, declared that an authoritative estimate to meet the new Act maintained that the intake of dentists would have to be three times as great as at present (*Lords Hansard*, Oct. 8, 1946, column 45).—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

## National Health Service

SIR,—I, like many others, feel that the sands are running out in connexion with the nationalization of the medical profession. At the moment all is apparently quiet on the horizon. The Minister of Health is being entertained by certain of the royal medical societies and all is peaceful. But one morning we shall wake up to find the profession in the position of a third-rate Civil Service, and all is lost. The Socialist Medical Society is working quietly but effectively in spreading their propaganda in town and country, and unless we rouse ourselves we shall find ourselves "too late"—as Carlyle remarked, "the two saddest words in the English language." May I suggest, that, as the vast majority of the profession in the British Isles oppose the nationalization of the profession, it is a duty incumbent upon all of us, to the public and to ourselves, to inform the public upon every possible occasion of the position of affairs. Many opportunities occur—to the general practitioner especially—in the course of casual conversation after purely medical questions are settled. The public are intensely interested in all matters associated with illness and the cure and care of the sick, especially women, and naturally so.

Having been qualified just on fifty years, I can definitely say that I have never personally known a medical man put his comfort or self-interest before that of his patient, and I believe the public have that same point of view. The influence of the medical profession in this country is enormous, and should now be used to further the best interests of both the public and the profession, which are identical.—I am, etc.,

Burwash, E. Sussex.

HOWARD M. STRATFORD.

SIR,—May I request a little space in which to take up one or two points raised by Dr. C. Grantham-Hill and Dr. A. E. Moore (Oct. 25, p. 97), the more so since circumstances have prevented my seeing the earlier letters to which they refer and I may therefore hope to be unprejudiced in comment on theirs? Although I cannot claim Dr. Grantham-Hill's length of experience in a Government medical service I can claim half that length much more recently—in the R.A.M.C. during the last war, following six years' general practice, which followed nine years' mixed experience of hospital and general work. I have not yet, even in the orderly medical officer system of the Army, or in co-operation with others in practice, found a rota system in which the man on duty was not glad to have his duty taken for him; and more than once found it was becoming customary to ask officers known to be accommodating to "hold on," with the sanction (verbal and easily obtained) of higher authority, for periods of a few minutes to hours or even to a complete exchange of duty. On occasion reciprocal courtesy was asked and received.

I am, if I may say so, entirely at one with Dr. Grantham-Hill's argument and attitude, but I cannot share his fears that any system, if introduced, will not prove as flexible. I would suggest that the trivial cases, after trying to get their money's worth, will—also because they are human—revert to waiting till they know their own doctor is available instead of calling in a stranger, that it will not do the rota doctor any harm to find out what is wrong with the borderline cases, and that he will have enough common sense and courtesy to pass on the serious case immediately he knows it belongs to a man who wishes to see such cases for himself, on or off duty.

Nor can I, wrong though I may be, easily visualize even the camarilla of Dr. Moore's nightmare attempting to interfere with reasonable flexibility of a rota system or anything else tending to improve the efficiency of the service. Except for the self-seeking politicians whose colour is not quite clear, all these bogies belong to the party which will, by the patients who are electors, be judged responsible for the Service. Hardly anything could contribute to the downfall of the present Government more certainly than a breakdown of a service they claim as peculiarly theirs—which it is therefore to be presumed they would wish to avoid. And a politician who from a place of power in any other party sought to destroy it by undue interference after it was working well would clearly be courting too much unpopularity to be anything but quixotic. Nor, whether Dr. Moore is right or wrong as to the result of the Government becoming the owner of all private practice in England, can that

come about under the present or, one may say, any foreseeable future Act. It is, I understand, anticipated in the present Act that everyone will continue private practice among people who do not wish to take advantage of the Act; and it is, I find, also thought that some practitioners will desire to stay outside it altogether, which it leaves them open to do.

A man who really believes that he surrenders professional independence by joining any service will probably receive the reward of his convictions by finding a competence outside it. I can well remember as a boy being told by a very senior practitioner that his son, then in practice, would of course not touch the panel and therefore had no need of the expense of a car. For Government to become the owner of all private practice in England a directly confiscatory Act like that concerning the railways would be necessary, with, in our case, prohibition of practice outside the Service, with about as much result as any prohibitive legislation there may now be against faith healing or herbalists.—I am, etc.,

Bristol.

C. T. NORRIS.

SIR,—The time is now approaching when we have to make up our minds whether we are prepared to serve in the new Health Service. I understand that when the N.H.I. Act was brought into force a number of those who had been most vociferous in opposing the Act were the first to join up, and I consider it most important that such a fiasco should not occur again. I therefore suggest that each vote against accepting service should be accompanied by a legal agreement binding the voter to pay a substantial sum to the defence fund in the event of his accepting service without the consent of the B.M.A. or a further plebiscite. The amount should be at least one year's emoluments under the new Service or the compensation value of his practice, whichever is the greater, and he should agree to pay over 25% of each panel cheque until the whole sum has been paid.

If such a guarantee were given against the breaking of one's pledge it would make each signatory much safer, and further it would enormously enhance the value of the plebiscite, for in the event of a substantial majority against acceptance it would show that the profession really meant business. I for one do not intend to bind myself to stop out of the Service unless I can be sure that others will not vote "No" and then later sign up. This time it is a question not only of the loss of large numbers of patients but also the loss of compensation for our practices.—I am, etc.,

Birmingham.

C. H. HEATON.

## Association Notices

AREAS OF MID-ESSEX AND SOUTH-EAST ESSEX  
DIVISIONS

Notice is hereby given by the Council to all concerned that the urban district of Burnham-on-Crouch and the rural districts of Southminster and Bradwell-on-Sea have been transferred from the South-east Essex Division to the Mid-Essex Division.

CHARLES HULL.

Secretary.

## Branch and Division Meetings to be Held

GREENWICH AND DEPTFORD DIVISION.—At Seamen's Hospital, Greenwich, S.E., Wednesday, Nov. 19, 8.30 p.m. Clinical meeting.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Nov. 20, 7.15 p.m. Clinical Demonstration in the Dental Hospital by Prof. J. Boyes: Diseases of the Oral Mucosa; 8.45 p.m., Address by Mr. R. C. L. Batchelor: The Role of Penicillin in the Treatment of Venereal Diseases.

SUNDERLAND DIVISION.—At Sunderland Royal Infirmary, Thursday, Nov. 20, 3.30 p.m. Annual Address by Prof. Sydney Smith: Alcohol and Behaviour. 7.30 p.m. Annual Dinner.

Correction.—In our report of the Annual Panel Conference (Supplement, Nov. 8, p. 106) Dr. F. E. Gould was incorrectly said to be representing Wolverhampton. The city should of course have been Birmingham.

LONDON SATURDAY NOVEMBER 22 1947

## SHERRINGTON'S IMPACT ON NEUROPHYSIOLOGY\*

BY

JOHN F. FULTON, M.D.

Professor of Physiology, Yale University

It has been said that *The Integrative Action of the Nervous System* ranks in importance with Harvey's *De Motu Cordis*, for it, like the classic on the circulation, marked a turning-point in the history of physiological thought.

The new printing of Sherrington's great monograph, which appeared earlier this year at the time of the Seventeenth International Physiological Congress, has served to remind the physiological world not only that Sir Charles is still following the main currents in the field—as is brilliantly indicated in his foreword to the new printing—but that he has retained his youthful outlook and the crisp critique which his friends and admirers have always learned to expect from his pen.

### His Early Work

An appraisal of his many contributions to neurophysiology and his position in the history of the subject is no easy task, for Sherrington has touched upon so many of its important phases. He began to publish in his late twenties. His first paper, which was issued in conjunction with J. N. Langley in 1884, had to do with the degenerations in the medulla oblongata and the spinal cord of one of the decorticate dogs which had been exhibited by Goltz

at the International Medical Congress of 1881. Thereafter, and until the beginning of the Second World War in 1939, he continued to publish papers and books, his titles averaging from one to fifteen a year. There are

few parallels in the history of medical literature to such sustained productivity. His output appeared to drop off during the war years, when he was engaged on two monumental works of scholarship—*Man on His Nature* and the biography of the sixteenth-century French physiologist and physician Jean Fernel which was issued by the Cambridge University Press in 1946—works that have brought him widespread acclaim.

Although his first paper had to do with the nervous system, Sherrington did not immediately confine his attention to this field. In 1885 he accompanied C. S. Roy and J. Graham Brown to Spain to observe an epidemic of Asiatic cholera. The following year he went to Italy on a similar mission and took the necropsy material to Berlin, where he began to cut the sections in Virchow's

laboratory. After two unsatisfactory months Virchow, who was then chiefly interested in politics, looked into Sherrington's work and sent him to the laboratory of Robert Koch, where he took the prescribed six-weeks preliminary course in technique and eventually stayed with Koch for nearly a year (1887). During this time he attended Waldeyer's lectures in histology. On these various trips to the

Portrait of Sir Charles Sherrington, O.M., in the possession of the Royal Society. Sir Charles Sherrington is 90 on Thursday, Nov. 27.

\*The first of three invited contributions to celebrate the ninetieth birthday of Sir Charles Sherrington on Nov. 27.

The portrait, painted by the late Mr. R. G. Eves, R.A., is reproduced by the kind permission of the Council of the Royal Society

Continent he also worked under Goltz at Strasbourg in 1885 and again in 1895, and he spent a month with Pflüger at Bonn.

Sherrington's clinical work had been done at St. Thomas's Hospital, where he was appointed Lecturer in Physiology. In order to support himself, however, he became, in 1891, professor and superintendent at the Brown Institution, a veterinary hospital of the University of London financed by those concerned with the prevention of cruelty to animals. Sherrington believed that when an animal had mercifully to be put away it might serve the interests of its fellow creatures if observations could be made upon its basic physiological functions while under terminal anaesthesia. Such was his tact in persuasion and such was the confidence he inspired that he was permitted to conduct the affairs of the experimental laboratory almost completely unmolested. Here it was that he began his classic studies on motor and sensory segmentation. In analysing the distribution of the ventral nerve roots he laboriously stimulated each ventral root from the first cervical down to the last sacral and recorded which muscles were thrown into action. Although begun on cats and dogs, this work was later extended to the monkey; and the observations on the monkey were found closely applicable to the human subject. The sensory dermatomes were similarly mapped by studying the "area of remaining sensibility" when three dorsal roots above and three below the dermatome under study were severed. Once again he included all dermatomes from the high cervical to the sacral, and the sensory maps that resulted have proved the basis of all later work on sensory levels, both of man and of animals.

### A Classic of Modern Physiology

It was while engaged in these studies that Sherrington became interested in the sensory nerves to muscle, and in a paper published in 1894, "On the Anatomical Constitution of Skeletal Muscles," he laid the foundation of our knowledge of what he later termed the "proprioceptive" system. Prior to 1894 anatomical textbooks had tacitly assumed that all nerves going to muscle were motor nerves. With his characteristic habit of studying anatomical relations first (and then attempting to turn his anatomical facts into physiological language), Sherrington found that when dorsal root ganglia supplying nerves passing to a given muscle were removed a large proportion of the nerve fibres of the muscle nerve in question degenerated. He concluded that one-third to one-half of the nerve fibres passing to skeletal muscle nerves are sensory in character. What then, he asked, are the functions of the afferent fibres originating in skeletal muscle?

At that time it had not been established that the various highly differentiated endings, such as the muscle spindles and the other end-organs described by Ruffini and Golgi, were actually sensory in nature. Sherrington severed the ventral nerve roots supplying a particular muscle and reported: "In muscles from which all motor fibres have been entirely removed by degeneration I have never in a single instance failed to find every spindle met with in the muscle still possessed of perfectly sound myelinate nerve fibres. These myelinate fibres are traceable from sensory roots, and penetrate into the spindles and terminate within them." On the other hand, when he deganglionated the dorsal roots at corresponding levels all muscle spindles and Golgi tendon organs degenerated and disappeared.

This paper, as does that on decerebrate rigidity which appeared in 1898, stands as one of the classics of modern physiology. It led Sherrington at once to study the effects in animals of severing the dorsal nerve roots. He found

that the cutaneous nerves of a cat's paw could be completely severed and the animal would suffer no locomotor deficit. Indeed, the cat could walk up the rungs of a sloping ladder and drink a bowl of milk at the top of it without experiencing any difficulty; even though its paws were completely numb. If, on the other hand, the extremities were de-afferented by dorsal root section, the animal, although still possessing motor power, was ataxic in the extreme and was quite unable to negotiate the sloping ladder. Study of the animal's behaviour made clear that it had lost all awareness of the position of the extremities in space. Further examination revealed that tendon reflexes, such as the knee-jerk, were lost, and this incidentally served to establish the fact that the knee-jerk was a true reflex. These studies also shed important light on the clinical condition of tabes dorsalis, in which ataxia develops as a result of impairment of sensory pathways at the dorsal root level.

While the work on the dermatomes and sensory nerves to muscle was progressing Sherrington was also studying the reflexes observable in the spinal and also in the decerebrate state. The celebrated series of papers on reciprocal innervation of antagonistic muscles began to appear in 1893 and continued until after the turn of the century. It was the analysis of the reflex behaviour of antagonistic muscles that led him to the concept of integration. By 1895 his papers had attracted such wide attention that he was called in that year to the Chair of Physiology at Liverpool, where he remained for eighteen years until he went to Oxford in 1913. Before leaving the Brown Institution he had begun to study the motor cortex of monkeys, but since his observations were in rather sharp disagreement with those recorded a few years earlier by Sir Victor Horsley he at first published them only in preliminary form. Sherrington's painstaking map of the motor area had indicated sharp restriction of the motor foci to the precentral convolution, and only when very strong stimuli were used could responses be obtained from the postcentral convolution. The more diffuse maps which Horsley had published Sherrington believed to be due to spread of stimulating current.

### His Silliman Lectures

These early phases of Sherrington's work culminated in his Silliman Lectures at Yale University, delivered in 1904 and issued in 1906 under the title already mentioned, *The Integrative Action of the Nervous System*. Here we find a host of new terms and phrases that have become household words in modern neurophysiology. He had introduced the term "synapse" when writing for Sir Michael Foster's *Text-Book of Physiology* in 1897, but the word did not really take hold until the Silliman Lectures had been published. The term "proprioceptive" was also given general currency in the Silliman Lectures, as was the related term "noeceptive." The cerebellum he described as the "head ganglion of the proprioceptive system."

The influence of *The Integrative Action* proved to be far-reaching in many spheres. The chapter on the motor cortex contained the first general summary of Sherrington's studies on stimulation and ablation of discrete areas. He pointed out that in chimpanzees, oranges, and gorillas the foci of motor representation were arranged in accordance with a definite pattern and that the same general pattern must obtain in the human being. He stressed the fact that the finer movements of the digits had a greater area of representation than the coarser movements such as the hip flexion; and by the same token that lesions of the motor area caused greater deficit for finer movement patterns of the digits than for the coarser movements of the

and shoulder. It is not surprising, therefore, that movement patterns having the least representation in the cortex were the first to recover after a cortical lesion. These observations proved immediately applicable in accounting for the clinical picture of hemiplegia in man, where recovery of motor function proceeds from the proximal to the more distal musculature—i.e., the hip muscles commonly recover motor power before the knee and the knee before the ankle.

### Work on Decerebrate Rigidity

"The integrative action" also revived the Hughlings Jackson concept of release of function to account for decerebrate rigidity and the rigidity of hemiplegia. Thus he says: "Hughlings Jackson with characteristic penetration of thought argued nearly thirty years ago that rigidity ensuing in hemiplegia (hemiplegic contracture) is not owing to the cerebral lesion nor to the lateral sclerosis." Jackson concluded rather that the extensor rigidity stems from unantagonized activity of subcortical centres, possibly from the cerebellum.

Sherrington's analysis of decerebrate rigidity itself, which followed the pattern of his celebrated paper on the subject published in 1898, is characteristic of his approach to a scientific problem. He began with a lucid description of the attitude assumed by the decerebrate monkey: "The hand of a monkey is turned with its palmar face somewhat inward. The hind limbs are similarly straightened and thrust backward; the hip is extended, the knee very stiffly extended, and the ankle somewhat extended. The tail in spite of its own weight, and it is quite heavy in some species of monkey, is kept either straight and horizontal or often stiffly curved upward." He then added that when limbs or tail, head or jaw, are pushed from the pose they have assumed, considerable resistance is felt, and "on being released, they spring back at once to their former position and remain there for a time more rigid than before." He found that deep anaesthesia abolishes the rigidity, but section of the dorsal columns of the spinal cord fails to abolish it; section of one ventro-lateral column of the cervical spinal cord, on the other hand, destroys the rigidity in the fore and hind limbs of the same side. It was also destroyed in a given extremity by posterior root section. This classical analysis of the decerebrate state stands as the corner-stone of modern neurophysiological teaching.

### The Stretch Reflex

After accepting the chair at Oxford, Sherrington devoted his attention to a more minute analysis of individual reflexes. With Frederick Miller he described the swallowing reflexes of the decerebrate cat, pointing out that one of the most effective stimuli of the swallow was a few drops of 30% alcohol. Probably his most important discovery in this later period was that of the stretch reflex, made in 1924 with his colleague, E. G. T. Liddell, who has succeeded to his chair. It had never been entirely clear to Sir Charles why the antigravity muscles could continue in a state of persistent contraction for an indefinite period without some obvious source of stimulation. He had found that the labyrinth could be destroyed, the neck muscles denervated, and the antigravity action still continued. In a given extremity he could denervate the skin and every other muscle save for the one under study—e.g., quadriceps—and the rigidity still continued in that muscle so long as its nerves were intact. Hence the stimulus for maintaining rigidity must arise in the muscle itself, presumably through some of the sensory endings which he had studied so successfully in 1894. When the quadriceps was detached from its insertion in the patella

and allowed to shorten, the sustained contraction of the decerebrate state disappeared; if now the tendon were pulled upon, a sustained reflex contraction ensued—a "stretch reflex" had developed. The stretch of the muscles imposed by the muscle's normal anatomical attachments thus proved a sufficient stimulus to cause sustained contraction. The analysis of the stretch reflex was typically Sherringtonian, and the paper describing it proved as significant as anything that had appeared from Sherrington's pen since *The Integrative Action*.

While preoccupied with the stretch reflex Sherrington turned once again to an early interest—namely, the nature of central inhibition—and in 1925 published his principal paper on the subject. Another interest, which began with his study of sensory-nerve endings in 1894, was the ultimate unit of reflex action. In the case of the stretch reflex it seemed probable that the muscle spindle was the afferent receptor, but the morphological character of the motor unit had received little attention. It was known that following degeneration of sensory-nerve fibres in a muscle nerve the remaining motor fibres were far fewer in number than the muscle fibres in the muscle itself. With J. C. Eccles in 1930 Sherrington discovered that the average motor unit—i.e., the ventral horn cell and the group of muscle fibres which its branching axone innervates—is capable of developing some 10 grammes of tension. Sherrington's pupil, Dean Clark, made nerve and muscle fibre counts of the de-afferented preparations that Eccles and Sherrington had used to determine the contraction values of the motor unit, finding that the ratio of nerve to muscle fibres was approximately 1 to 140—so that on an average a single anterior horn cell controls more than a hundred muscle fibres.

### The Philosophical Aspect

The philosophical implications of Sherrington's studies on the nervous system have often been discussed by his contemporaries, but Sherrington himself remained almost stubbornly silent on the subject until his Rede Lecture, delivered at Cambridge in 1933. Here we find him discussing the brain as an organ of the mind. He has allowed himself similar liberty in the Foreword to the 1947 edition of *The Integrative Action*. In the Rede Lecture he sounds somewhat frustrated when he asks:

"But indeed, what right have we to conjoin mental experience with physiological? No scientific right; only the right of what Keats, with that superlative Shakespearian gift of his, dubbed 'busy common sense.' The right which practical life, naive and shrewd, often exercises. To many of us a mere juxtaposition of the two sets of happenings proclaims their disparity. On the one side changing electrical potentials with thermal and chemical action making a physiological entity held together by energy relations; on the other, a suite of mental experience, an activity no doubt, but in what if any relation to energy? As for me, what little I know of the how of the one, does not, speaking personally, even begin to help me toward the how of the other. The two, for all I can do, seem to remain disparate and disconnected."

In 1947 one detects a similar note:

"In all those types of organism in which the physical and the psychological coexist, each of the two achieves its aim only by reason of a *contact utile* between them. And this liaison can rank as the final and supreme integration completing its individual. But the problem of *how* that liaison is effected remains unsolved; it remains where Aristotle left it more than 2,000 years ago. There is, however, one peculiar inconsistency which we may note as marking this and many other psychological theories. They place the soul in the body and attach it to the body without trying in addition to determine the reason why, or the condition of the body under which such attachment is produced. This, however, would seem to be a real

question.' Instead of, as is usual in physiology, leaving that impasse unmentioned, it seemed better to draw attention to it by the experimental observations in this book's final chapter."

### Conclusion

And so we deem it a rare privilege to hail the man whose intellectual integrity has never allowed him to accept as truth anything that he has not proved to his own satisfaction. To the most profound student of the nervous system the world has yet known, the mind of man remains still unexplained. There are some, however, who may take issue with Sherrington when he modestly insists that the problem remains where Aristotle left it more than two thousand years ago; for many feel that Sherrington himself has pointed the road that will one day lead us to that goal. Some lines from *Ulysses* seem not irrelevant:

Come, my friends,

'Tis not too late to seek a newer world.  
Push off, and sitting well in order smite  
The sounding furrows; for my purpose holds  
To sail beyond the sunset, and the baths  
Of all the western stars, until I die.  
It may be that the gulfs will wash us down;  
It may be we shall touch the Happy Isles,  
And see the great Achilles, whom we knew.  
Tho' much is taken, much abides; and tho'  
We are not now that strength which in old days  
Moved earth and heaven, that which we are, we are—  
One equal temper of heroic hearts,  
Made weak by time and fate, but strong in will  
To strive, to seek, to find, and not to yield.

For a complete bibliography of Sherrington's writings see appendix to the new edition of *The Integrative Action of the Nervous System* (Cambridge University Press, 1947). A full bibliography is also to be found in Denny-Brown's *Selected Writings of Sir Charles Sherrington* (London, Hamish Hamilton, 1940).

## SHERRINGTON—THE MAN

BY

T. GRAHAM BROWN, M.D., F.R.S.  
Professor of Physiology, University of Wales

"Such old enchantment as a boy's  
when life first whispers use of life  
entranced me . . ."

The words are from Sherrington's own verses on Ifley Church, and they confess a spell which in his case has been so strong and lasting that it is almost impossible to believe that we are called on to celebrate the ninetieth birthday of a heart so young. The occasion indeed calls for celebration, but it is difficult for a friend to pay adequate tribute to so essentially living a man, and the task is made the harder by Sherrington's own unself-conscious modesty, which springs from his intense interest in the outside world but nevertheless makes him vulnerable to shafts of honest praise. But he belongs to the world, and not to himself.

Sherrington was born on November 27, 1857. After leaving his school at Ipswich he began his medical studies at Edinburgh, where he was happy, but whence he was soon transferred to Cambridge to be there with his brother. On entering Caius College, his real Alma Mater, in 1880, he took his full part in its life—intellectual, social, and physical. Although slight of build he was fast on his feet and wiry, and in spite of his lightness he played as a forward in the college XV—a fact which says much for his athletic quality. His short sight, which forced him to use glasses, prevented him from taking much part in other games, but later in life he climbed in the Alps until about the time of his marriage, and it is easy to understand how he has retained an interest in, and a sympathy with, athletic games and sports.

### Early Influences

He was at this time greatly influenced by the men, such as Michael Foster and Gaskell, who were then playing their great parts in advancing the young British school of physiology and were bringing the spirit of experimental science into medical research and education as a whole. That spirit ultimately derived from the great experiments of this country who had formed the Royal Society in the seventeenth century; but so far as medical science was concerned, the experimental method had flourished more vigorously in Germany during the period just before the Franco-Prussian War of 1870-1, when it had been brought back from Germany to its original home. In Sherrington's undergraduate days the heaven had so far chiefly affected physiology: anatomy remained a purely topographic study; pathology, not yet established as a chair at Cambridge, was largely a matter of the post-mortem room and the museum.

We may picture the young Sherrington as at first captured by the experimental spirit rather than by physiology as a special field for its adventure; but the picture will also show an unusually keen, inquiring, and zealous undergraduate who not only took a catholic interest in many subjects, but was also urged by his curiosity to learn what he could about the objects of his manifold interests. Above all, he projected himself, as it were, on to the external world, and to that are due his absence of self-consciousness and, closely related thereto, the modesty, too unstudied to be shy, which is sometimes almost an embarrassment to his friends.

Towards the end of his time at Cambridge he was Demonstrator in Anatomy, and then, having taken Part II of the Natural Sciences Tripos with first-class honours, he went on to London in 1884 for his clinical studies at St. Thomas's Hospital. In that year also he held the George Henry Lewes studentship for physiological research at Cambridge, and his first scientific paper, a largely histological examination of the nervous system of one of Goltz's decorticated dogs, was written in collaboration with J. N. Langley. During the winter of 1884-5 Sherrington worked for a time in Goltz's Physiological Institute at Strasbourg, where C. S. Roy had held the post of assistant a few years before.

### Experience Gained Abroad

In 1885 Sherrington obtained his membership of the Royal College of Surgeons, and in the same year he was sent by the Royal Society with C. S. Roy and J. J. Graham Brown to investigate the outbreak of Asiatic cholera in Spain, where these lifelong friends spent the summer and autumn. Of the three, Sherrington proved to be the best linguist, and to him fell the difficult and aggravating negotiations with the various officials who, properly prevented access to the cordoned-off villages, but who could be induced with equal propriety, and by the traditional local method, to let the investigators pass. His mastery of the language led Sherrington to take an interest in Spanish literature, and particularly in the Spanish dramatists; and to it he also owed his friendship with Ramón y Cajal, who stayed with him in London some years later. The obituary notice of Cajal which Sherrington wrote for the Royal Society in 1935 is a tribute not only to that friendship but also to his own capacity for deep feeling. Not least among Sherrington's merits is his gift for solid and disinterested friendship.

After these pathological studies, and during the winter of 1885-6, Sherrington returned for a time to physiology at Cambridge, where Roy, who had been the first George Henry Lewes student in Sherrington's undergraduate days (1881), was now the newly appointed first Professor of Pathology. Later in 1886 Sherrington

investigate another outbreak of Asiatic cholera, and he hereafter spent more than twelve months in Germany, examining his pathological material in Virchow's laboratory and then more profitably with Koeh, but also working in Berlin at experimental physiology with Zuntz and at histology with Waldeyer. On returning home in 1887 he became Lecturer in Physiology at St. Thomas's Hospital, his first independent post. In later years he worked again with Goltz in Strasbourg, and for a short time with Mûlger in Bonn, and elsewhere.

This foreign experience was a strong factor in Sherrington's subsequent development and in his general attitude to academic study. The great German masters of these days had been bred in the traditions of the idealistic, almost pastoral, Germany which existed before the beginnings of industrialization and materialism that followed closely on the Franco-Prussian War and on the creation of the German Empire of the Hohenzollerns. In that older Germany, which persisted in the strongholds of the universities, the ideal of academic liberty and the belief in the obligations as well as in the dignity of the academic life were felt to require open expression and assertion if they, and what they stood for, were to be maintained intact and handed on from master to pupil.

In that atmosphere loyalty was given above all to the objects for which an Institution was the instrument rather than to the Institution as such, and nowhere was this spirit stronger than in Strasbourg. Sherrington had been captured by the missionary spirit of his teachers at Cambridge. At Strasbourg, his first foreign experience, he again met it. When the Prussian Government refounded that university soon after the annexation of Alsace as a spoil of the Franco-Prussian War, the new chairs were offered to the best men in Germany, who regarded it as a point of honour not to refuse the call. The missionary spirit which moved that brilliant group of men was further strengthened by the local atmosphere which prevented social contacts between Germans and Alsations and, even up to the time of the first world war, made it impossible for the two to drink their midday coffee at the same restaurant on the Kleberplatz. The isolated Germans could not have failed to feel, as in fact they did feel, that they held their chairs *in partibus infidelium*, and, as a necessary effect, their strong academic idealism seemed to call more than ever for conscious expression, almost fanatical.

The beginnings of the anti-vivisection crusade had already caused something of the same sort to happen at home, and to the impact of these missionary atmospheres may perhaps be ascribed Sherrington's strong views about academic liberty and intellectual honesty, his clear vision of the objective beyond its instrument, his belief in the fearless but judicious expression of opinion, his hatred of academic or political expediencies, and his distrust of what he calls "institutionalism"—the concentration of personal loyalty on the corporation rather than on the end for which it is devised. His rare anger is roused by sins against his own high ideal, and by little else except unworthy conduct, or meanness, or (as a passing flash) the culpable ineptitude of some unfortunate assistant. He taught one that in all things only the best is good enough, but he could sympathize even with our shortcomings.

#### His Contributions to Knowledge

Sherrington became professor-superintendent of the Brown Institution in 1891, and his marriage in 1892 began a continuously happy partnership with the lady to whose kindness we all owed so much. During the four years of his work at the Brown Institution before he succeeded Gotch as Professor of Physiology at Liverpool in 1895, Sherrington's scientific interest definitely turned to the

subject which became his life's work. Before 1891 the greater number of his contributions to knowledge had been concerned with the structure of the nervous system; thereafter, the localization of function, as in the spinal roots, attracted him; and his interest in the clinically significant knee-jerk led him finally to the study of reflex function itself, as is described elsewhere by the able pen of Professor Fulton. Here again he gave his loyalty to the end rather than to the instrument—to function rather than to structure—and the parallel is revealing.

As a lecturer Sherrington had defects due to his own scrupulous search for exactness and clarity. He would pause, seeking the only word or phrase which would convey his precise meaning, and his dislike of dogmatic assertion caused him to insert qualifications and corrections as if in brackets. This would lead to hesitations and complexities, and it gave the impression that his own thought was being created and moulded as he went along. The ordinary student, fresh from the unequivocal teaching of the anatomy class, disliked the mental effort of learning which Sherrington's lectures demanded; but to those who wished to learn the effort was itself educative, and both the matter and the manner were fascinating. Similarly, his published work at first appealed to a limited circle, although within that circle the appeal was strong; and this was perhaps to be expected where a new terminology had to be invented in what was to all intents and purposes a new field, where the subject itself was of great complexity, and where the results might strike the unthinking as purely "academic"—that is, as of little practical significance. Even the importance of Sherrington's *Integrative Action of the Nervous System*, which was published in 1906 and is now recognized to be a landmark in physiology, was realized somewhat slowly by the generality.

#### His Varied Interests

It was to those who worked in his laboratory that Sherrington gave most and showed most. The research student would enter it, timidly, with a mental picture of the author of *Integrative Action* as a man who must dwell in a sphere of his own making, difficult to attain or to travel in—a man necessarily aloof and out of common reach, "academic," coldly intellectual. But the disarming spirit of equality with which the recruit was received at once destroyed a mental barrier which could not in any case have for long withstood the sympathetic friendship which was offered by Sherrington and earned lasting friendship in return. There was no pomp, no vestige of that Olympian arrogance which was so evident in some of the larger German institutes of the time. The laboratory life was a continuing adventure with always widening horizons. Chance talk would reveal what (but only at first) seemed to be Sherrington's surprising interests outside his own sphere—the Roman Wall, the Dutch masters of painting, Gothic architecture, old books and out-of-the-way bypaths of literature, the history of mechanical inventions, poetry (with strong preferences—Keats for one, and Tennyson, when the latter was still under a cloud in Bloomsbury), the Darwinian theory of evolution, the aesthetic movement of the 1880's, Canada, and all things youthful and adventurous. These in their turn would disclose unsuspected capacities for feeling and depths of feeling, as did Sherrington's own occasional verses. It was indeed possible, without self-consciousness, to show one's own verses to Sherrington—a thing which speaks for itself. In his emotions, too, Sherrington was catholic, and he would be moved not only by the beauty in a picture, or in an act, or in a mountain scene, but also by the beauty of an experiment or of an ingenious technical method. And always there was originality and insight. What would

delight the pupil was less the width of Sherrington's interests than the depth of his knowledge in each; and by the time the pupil had replaced his first crude picture with that of a many-sided, a lovable, and a very human man he himself had received a liberal education.

In such matters Sherrington for long kept himself to his intimate circle of friends except for the rare event of such verses as those in which he wrote of Canada in 1911, and the later poems to which he was moved by the first world war. It is true that he published some of these in *The Assaying of Brabantius* in 1925, but it was not until after he had retired from the chair of physiology at Oxford in 1935 that he really began to give the ordinary cultured reader what he had given to his happy laboratory or at his own fireside. Three articles in the *Cornhill Magazine* of 1936 and 1937 may be instanced here, as also his penetrating essay on *Goethe* (1942) and some remarkable reviews such as that in *Nature* (1937) on Ramón y Cajal's *Recollections*. But amongst all the works of these recent years there stand out his two memorable books—*Man on His Nature* (the Gifford Lectures given at Edinburgh in 1937-8 and published in 1940) and *The Endeavour of Jean Fernel*, which appeared only last year. When we reflect that these multiform activities are the work of a man in his ninth decade and sadly hindered by arthritis, we can only marvel at the persisting strength of the enchantment cast by Sherrington's youthful spell. And now, because it is the privilege of the recipient to ask for more, we may send our greetings and our thanks to Sherrington with fervent hope that he will long be preserved to add to the debt which we already owe him, and to continue what he himself expressed in *Brabantius*:

"Impulsion stirred me, resolute  
with heart a-search and hastened foot,  
to work men service. . . ."

## SHERRINGTON AS PHILOSOPHER

BY

A. D. RITCHIE, M.A.

Professor of Logic and Metaphysics, University of Edinburgh

It should be the task of the philosopher to review critically the thought of his day, taking the various specialist modes of approach in a wider setting than is needed for a purely specialist treatment and trying to attain to a more comprehensive or synoptic view. There is an aspect of this task which is often forgotten and seldom rated as highly as it deserves. That is the interpretation of the thought of the past so as to make it intelligible to the present. In scientific subjects it is easy to get a distorted perspective unless we understand how recent thought has grown out of the earlier stages through the efforts of the pioneers, who nearly always mingled acute insight with confusion.

Because this work of interpretation is generally underrated I mention first Sir Charles Sherrington's exposition of the ideas of Jean Fernel in *Man on His Nature* and in his more recent book *The Endeavour of Jean Fernel*. In the fifteenth century, though Vesalius and Copernicus were at work, no branch of science except mathematics had yet reached a firm basis. Medicine was still weighed down by misunderstood tradition, bogus information, and downright superstition, astrology specially. Though scientific medicine belonged to the future, Fernel was struggling towards the light in a most interesting and suggestive way. To interpret that struggle requires sympathetic insight, a firm grasp of principle, and much hard work to see what lies behind confused and archaic terminology and to reconstruct

forgotten ideas. The book on Fernel is a masterpiece, and—that very rare combination—a book that is a pleasure to read and also a work of scholarship in the strictest and most academic sense. In his lecture *Goethe on Nature and Science* Sir Charles shows the same skill in interpretation. Of course the reason for his skill is not far to seek. The author is both a poet and a man of science.

### His Gifford Lectures

However, the philosophy of Sir Charles will always be judged by *Man on His Nature*, in which he took the opportunity afforded by the Gifford Lectures to survey the relations of the material, the living, and the conscious as displayed in the functioning living organism in general, and more especially in the functions of the nervous system. He also considered the place of mind or conscious life in the universe as a whole. The modern sciences of physics and chemistry, he argued, have expanded and sharpened our conceptions of material things so that the old simple-minded view that life is a kind of fire, which passed muster in the days of Fernel, is now dropped except as a metaphor, apt in one respect but misleading in all others. If greater knowledge of the material world has sharpened certain distinctions and abolished old fallacies it has not solved the main problem of the relation of the material and the mental; indeed, it has raised new problems. The physics and chemistry of the living body are peculiar and complex, but still physics and chemistry.

In the purely material realm things and processes, though in some respects continuous, are in other respects "granular," wrapped in bundles all separate and all similar—the quantum of action, the electron, the atom, the molecule. In the organic realm there are also "granular" entities on a larger scale that are fundamental—the gene, the nervous impulse, the cell. There is in addition a process of co-ordination or integration at work, operating through purely physical and chemical means, yet exemplifying an order over and beyond the physical order. In spite of this integration, the most elaborately integrated of all organisms, the human, though possessing a master organ, the brain, possesses no master cell. Instead, the highest centres of the brain appear to be a kind of republic of millions of cells. Where does the mind come in? Mind is certainly not granular in the way that atoms and nervous impulses are. It is not a special kind of matter or of energy, as earlier speculators often suggested.

The bodily organism which contains millions of cells can do a number of things simultaneously by means of reflexes and acquired habits, but the mind attends to one thing at a time. It goes so far as to see one visual field through the medium of two distinct organs. Moreover, for a great deal of psychology knowledge of brain function is irrelevant. This is seen equally in the modern work of the psychoanalytic school and the many excellent psychological observations of Aristotle, who associated the heart, not the brain, with conscious life.

### Association of Mental Process and Bodily Functioning

In all this discussion Sir Charles brings out clearly the close association of mental process and bodily functioning, and at the same time the difficulty, if not the impossibility, of completely identifying the mental with any kind of structure or activity of the body. Aristotle in his own way seems to have felt the same difficulty. He conceived of a hierarchy of bodily activities, the higher developing out of the dependent on, and yet fulfilling the lower. Sometimes he seems to identify the highest bodily activity with reason, activity and sometimes to consider mind as distinct and perhaps even separable, following Plato to that extent. Sir Charles's conclusion is that man is really part of the

natural world from which he has developed, yet his mind in some way distinct and able to judge that world as rough from outside by means of its own conception of value. The world so judged is often found wanting.

A striking part of the discussion is the account of the life history of the malaria parasite and its implications for human life. From the point of view that I may perhaps be allowed to call plasmodio-centric, the story reveals a triumph of adaptation to environment. From the anthropocentric view the triumph is a terrible curse, one of the great disasters. Malaria has destroyed whole civilizations and still brings death and misery to millions. We cannot avoid believing that in this matter the anthropocentric view as a cosmic significance which the plasmodio-centric lacks. We deny that *Plasmodium* has as good a claim to be heard as *Homo*. However, if human moral judgment leads us to condemn some of the happenings of the natural world and approve of others, that is to be taken as a challenge to action, to maintain what is right and alter what is wrong. So far, but no farther, Sir Charles goes beyond his original starting-point of purely natural knowledge, because an honest acceptance of fact compels him to do so. He takes throughout his own line and works things out his own way, but he supports the testimony of a number of thinkers of our time who have deliberately started out from a naturalistic standpoint and found themselves forced to go beyond it by sheer pressure of facts. Alexander, Whitehead, and Laird may be mentioned, and also Woodbridge, in America. Where these thinkers differ most is after they leave the naturalistic view, and there Sir Charles has not committed himself. We must be grateful for what he has given us, expressed with rare felicity. When distinguished men of science, as Gifford Lecturers or otherwise, expound their philosophies they seldom do it so well. Above all, few have the skill in pilotage needed to avoid equally the Scylla of superficiality and the Charybdis of obscurity.

### The Synoptic View

In conclusion, perhaps I may turn to Sir Charles's more strictly physiological work, particularly *The Integrative Action of the Nervous System*. Before that book was published there were plenty of facts available but a singular

lack of the right concepts to interpret them. Sir Charles of course marshalled the known facts, adding a good many he had discovered for himself, but above all he provided the concepts which have been used ever since. Pre-Sherringtonian physiology of the central nervous system reminds one of the Oriental tale of the four blind men who examined an elephant. One seized a leg and said the elephant was a kind of tree; another a tusk and proclaimed it a kind of spear; the third the trunk and found it like a snake; the last got hold of the tail and said it was just a rope. Every statement reports a fact, and up to a point does it correctly; but they do not hang together.

The nervous system does contain converging and diverging paths; but how are they interconnected? Its functional unit is the reflex; but how are reflexes interconnected? A reflex does work rather like a penny in the slot machine, but not altogether; what are the differences? Given the Sherringtonian conceptions, anatomical and physiological facts could be seen in a new light—seen all together in a synoptic view and each also better seen in detail. Some of the important points have been well summarized in the foreword added to the new edition of *The Integrative Action*. Any reflex even at the lowest end of the scale operates as part of a system and uses the motor organs of the animal as a whole, though not all at once. It is not a matter of one bundle of receptors, one bundle of paths, and then one bundle of muscles. At the same time, a reflex has a permanent and apparently innate anatomical basis, so that it is an error to confuse reflex action with acquired habit. These more adequate conceptions are not so very easy to grasp; it is much easier to slip into the penny-in-the-slot view and to forget the limitations of reflex action—indeed, it is frequently done.

I mention these points because here, within a definitely restricted scientific sphere, Sir Charles has done the kind of thing the philosopher is always trying to do in a less restricted sphere with rather partial success. In some branches of science it may be possible to do without the synoptic view and see each thing separately; the trees may be more important than the wood. That is hardly possible in physiology, certainly not in the physiology of the nervous system.

## METABOLIC DISTURBANCES AFTER INJURY\*

BY

J. BEATTIE, M.D., D.Sc.

Bernhard Baron Research Laboratories, Royal College of Surgeons of England

It is remarkable that the existence of a disturbed metabolic state after injury should have remained unrecognized until 1929, when Cuthbertson observed an increase in the urinary nitrogen output following fractures in experimental animals. Later work demonstrated that this phenomenon also appeared in well-nourished human subjects who had sustained injury. The pattern of the metabolic changes in human patients has been worked out in detail (Stevenson *et al.*, 1945). During the first week after injury the urinary nitrogen output rises to a peak and brings about a phase of negative nitrogen balance even on high-calorie and high-protein diets. The output declines until about two to three weeks after injury, when it equals the protein nitrogen input. This phase is called the "katabolic" phase. Following it the input and output remain about equal for a few days or a week, and then the nitrogen output tends to

decline and a phase of positive nitrogen balance begins. This lasts for a variable period, but is usually complete in two to three months after injury. This latter is the "anabolic" phase during which part at least of the nitrogen loss of the "katabolic" phase is repaired. The work of various investigators has shown that at least three factors condition the magnitude of increased nitrogen output in the "katabolic" phase—immobilization in bed, the severity of the injury, and the nutritional state of the individual at the time of injury.

### Effect of Confinement to Bed

Keys (1944) observed four normal well-nourished subjects who were put to bed for three to four weeks and allowed out of bed only to evacuate the bowels. At the end of three weeks the nitrogen losses were 51.7, 38.5, 58.6, and 43.5 g.; the body weights, however, showed no appreciable change. In the subject who lost 43.5 g. of

\*An abridgment of the Bernhard Baron Lecture given at the Royal College of Surgeons of England on July 4, 1947.

nitrogen the weight fell by only 0.86 kg. at the end of three weeks. With one exception all the nitrogen losses in the third week in bed were in excess of those observed during the first week (Table I).

TABLE I.—Nitrogen Loss from Confinement to Bed (Calculated from Keys's data)

Period	Nitrogen Balance per Period			
	Case 1	Case 2	Case 3	Case 4
Control .. ..	0	0	0	0
1st week in bed .. ..	-18.4	-13.4	-12.0	-12.5
2nd " " .. ..	-9.3	+2.9*	-21.5	-19.5
3rd " " .. ..	-24.0	-28.0	-25.1	-11.5
Total in bed .. ..	-51.7	-38.5	-58.6	-43.5
Ten days after getting up ..	+8.6	+5.3	+14.2	+27.4

\* Protein input raised from 54 to 200 g. protein for this week.

These findings are of great importance, for they show clearly that a protein intake of 54 g. a day is not sufficient to prevent nitrogen loss in a patient confined to bed on an adequate calorie input. On the other hand Keys noted that in two subjects confined to bed it was possible to bring about a state of positive nitrogen balance on an intake of 110 g. of protein a day. Positive nitrogen balance during the ten days immediately following the three weeks in bed was attained on a protein input of 84 g. a day (13.4 g. of nitrogen). The variations in the speed with which the lost nitrogen was restored were most remarkable, although the diets were identical.

#### Effect of Injuries of Differing Severity

The following studies indicate how the magnitude of the nitrogen loss varies with different types of injury (Table II).

TABLE II.—Operations and Injuries (Age of patients, 21-34 years)

Trauma	Negative Nitrogen Balance		Duration of "Katabolic" Phase (Days)
	G.	G. per Day (average)	
Appendicectomy {	26	2.2	12
	29	2.4	12
	37	2.2	17
Burns (lower limbs) {	201	5.2	39
Burns (hands and arms) {	216	4.6	47
Fracture of humerus ..	98	3.4	29
Fracture of femur ..	124	3.0	41
Osteotomy .. ..	32	2.3	14

The duration of the "katabolic" phase is given. This is measured from the morning of the day of operation in the operation cases and from the morning of the day after injury in the accident cases. All these patients were given diets which contained 2,750 calories and 100 g. of protein (16 g. of nitrogen) daily. On such diets Keys's data would indicate that normal uninjured persons confined to bed would have been in positive nitrogen balance or at least in nitrogenous equilibrium. The losses recorded in these cases of injury or operation may therefore be ascribed to the effects of the injury sustained. The total nitrogen loss and the average daily loss would seem to bear a direct relation to the severity of the injury, being highest in the cases of burns and lowest in the operation cases. Similar results have been reported by Browne and his group.

#### Effect of Undernourishment Before Injury

Browne *et al.* (1945) drew attention to the apparent absence of a "katabolic" response after operation or injury in persons who at the time of injury were in a poor nutritional state. Howard and Mason (1946) showed that when such people were put to bed they did not go into negative nitrogen balance as Keys's subjects did, and, moreover, when subjected to operation a negative nitrogen balance either did not develop or if one appeared it was of small

magnitude. The following case illustrates the absence of the "katabolic" response in a poorly nourished patient.

A man aged 65 was suffering from an annular carcinoma of the oesophagus. Owing to difficulty in swallowing, food had been restricted for about three months, and for three weeks before admission had been limited to fluids. He had lost about 20 kg. when admitted—normal weight, 64 kg. The late Mr. Tudor Edwards regarded the condition as operable and planned the removal of the section of the oesophagus containing the tumour and anastomosis of the oesophagus to the stomach within the thorax. The necessary freedom was secured by displacing the major part of the stomach into the left pleural space. The operation was successful and the patient recovered.

Before operation it was estimated that the patient was in nitrogenous equilibrium on a diet containing 1,600 calories and protein equivalent to 5 g. of nitrogen a day. On the day of operation and for the next six days he received by vein solutions of protein hydrolysate and glucose sufficient to provide 1,600 calories and 8.6 g. of nitrogen. Over the seven days the nitrogen balance was:

Input nitrogen ..	60.2 g.	Urinary nitrogen ..	51.8 g.
		Faecal nitrogen	
		(10% of input)	6.0 g.
			57.8 g.

There was thus an apparent but slight positive nitrogen balance equal to 0.34 g. of nitrogen a day. While such a small positive balance is of little significance, it is significant that he did not go into negative nitrogen balance.

#### Source of the Excess Urinary Nitrogen

Cuthbertson *et al.* (1939) showed that "katabolic" response was absent after injury in experimental animals which had been fed on a protein-free diet until their nitrogen excretion became constant. They suggested that the excessive output of nitrogen which follows injury arises from storage protein and not from essential tissue substances, as when the storage protein was depleted there was no increase in the output of nitrogen after injury. Body protein has been differentiated by Whipple into (a) "fixed" or indispensable cell protein without which cellular life ceases, (b) "dispensable" protein which can be yielded up by the cell as a source of energy during starvation, and (c) "labile" protein which can move out of or into the cell when the concentration of the plasma proteins falls or rises. Presumably Cuthbertson's storage protein can be equated with the sum of "dispensable" and "labile" protein of Whipple.

This protein may be present in the cell cytoplasm either as something apart from the cell protoplasm or as only a part of the cytoplasmic mass. If the cytoplasmic mass were reduced in quantity the cell would yield up not only protein but a quantity of its intracellular fluid. On the other hand it is conceivable that the cytoplasm could yield up protein while conserving its intracellular fluid. Howard and Mason (1946) found in cases of injury that nitrogen loss was not accompanied by a proportionate loss of potassium and phosphorus from the body. Presumably protein was yielded by the cell cytoplasm, but the intracellular fluid, which contains potassium and phosphorus, was conserved. Keys (1944), however, found in patients who were confined to bed but were otherwise normal that there was some potassium loss during the period when a negative nitrogen balance existed. Presumably such persons did lose some intracellular fluid. He noted that the body-weight loss was less than that which might be expected on the basis of the nitrogen loss. Both groups of experiments thus tend to support the idea that the body cells can yield up some of their protein without an proportionate loss of intracellular fluid. The evidence is therefore in favour of some part of the cellular protoplasm being "storage" protein. This, however, must not be taken

to imply that such protein is an inert store. It is difficult to estimate how much protein can be yielded up without causing death of the cell. Lusk (1928) calculated that the average human subject weighing about 68 kg. had a total nitrogen content of 2,000 g. Howard (1943) and Stevenson *et al.* (1945) have reported nitrogen losses of between 250 and 300 g. after fractures and burns. If all this nitrogen came from "storage" protein at least 15% of the body protein is available for the "katabolic" response. It is possible that when this amount of nitrogen is lost some mechanism may come into play to prevent destruction of more protein.

### Mechanism of the "Katabolic" Response

Present knowledge of the mechanisms involved in the "katabolic" response is extremely scanty. Some facts have been brought to light which may in the future be found to have some causal relationship to the increased nitrogen output after injury. It has been found in normal persons that a few days after injury the urine contains large quantities of a cortin-like material (corticosteroid). The amount may be from three to five times the normal amount. The peak output is reached by the end of the first week after injury and thereafter tends to decline, reaching the normal level at about the time when nitrogen equilibrium is established (Browne, 1942). There is thus some parallelism between the daily excretion of corticosteroid and that of nitrogen. This material when concentrated has the power of increasing the glycogen content of the liver. This effect is identical with that obtained after the injection of the cortin (corticosteroid) of the adrenal cortex. It is believed that this corticosteroid inhibits the synthesis of amino-acids into protein. Consequently these acids, if not utilized by the body, are deaminated by the liver and in part built into liver glycogen. Their nitrogenous fraction is transformed into urea and excreted. If it be assumed that the increased excretion of corticosteroid after injury represents an increased production of the substance and not a diminished utilization or an increased permeability of the kidney to them, it might be inferred that a causal relationship exists between increased corticosteroid production and increased nitrogen output. Such an inference is, however, not justified, for many reasons. Injections of pituitary corticotrophic hormone into normal persons induce an increased output of corticosteroid in the urine (Schenker and Stevenson, 1943), an effect which is not accompanied by a parallel rise in nitrogen output. Vénning (1944) has reported a case of burns which had a high corticosteroid output until the 28th day after the accident. Nitrogen excretion commenced to decline on the 21st day in spite of an increased protein input which had been given from the 12th day. The nitrogen balance in fact became positive before the level of corticosteroid excretion began to fall. This must mean that the "katabolic" response was waning at least 10 days before the corticosteroid output decreased.

It has been pointed out that in debilitated subjects injury does not lead to an increased output of nitrogen in the urine. The urinary corticosteroid excretion in such cases either is not increased or is reduced below the normal level. This lack of adrenal response to injury suggests that the explanation of Cuthbertson *et al.* (1939) that the lack of response was due only to absence of "storage" protein is not adequate. If such persons were given a large protein input after injury it might be expected that they would katabolize this extra protein as would a normal person who had been injured. The fact that they do not, but instead conserve the increased protein input, suggests that the mechanism for the "katabolic" response is being

inhibited. The following case shows how avidly the organism seizes on the extra protein in the input when injury is sustained in the debilitated state.

A child aged 14 received multiple injuries including fractures of both tibiae and fibulae and severe lacerations to one of the lower limbs. After 10 weeks in hospital the fractures had not united and epithelization of the lacerated area had slowed down considerably. Skin-grafting of this area failed. Observation for a week after the skin-grafting operation showed that the nitrogen input was 39.5 g. and the total nitrogen output 40.2 g. Calorie input averaged 1,520 calories a day. The calorie input was raised to 1,750 daily with a protein nitrogen content of 15 g. a day. Over this week the nitrogen balance was:

Nitrogen input ..	106.5 g.	Urinary nitrogen ..	38.5 g.
		Faecal nitrogen	10.7 g.
		(10% input) ..	49.2 g.

Positive nitrogen balance = 57.3 g., or 8.2 g. a day.

At the end of the week there was a noticeable improvement in the clinical condition and an active epithelization of the lacerated area. The denuded area from which the skin-graft had been taken was healing rapidly. The diet was increased to 2,100 calories and 22 g. of nitrogen a day. At the end of this week the nitrogen balance was:

Nitrogen input ..	160.3 g.	Urinary nitrogen ..	49.2 g.
		Faecal nitrogen	16.0 g.
		(10% input) ..	65.2 g.

Positive nitrogen balance = 95.1 g., or 13.6 g. a day.

After another week on the same diet the positive nitrogen balance was 81.1 g., or 11.6 g. a day. The total gain in nitrogen was 233.5 g. over a period of three weeks. It was then decided to skin-graft the lacerated area. During the following week, the first day of which was the day of operation, the nitrogen balance was:

Nitrogen input ..	132.7 g.	Urinary nitrogen ..	156.2 g.
		Faecal nitrogen	13.3 g.
		(10% input) ..	169.5 g.

Negative nitrogen balance = 36.8 g., or 5.3 g. a day.

Thus after a period of three weeks in a state of positive nitrogen balance a second operation provoked the normal response ("katabolic") which was lacking after the first. The clinical condition during this "katabolic" phase remained good and the skin-graft "took." Healing was rapid, and four weeks after the increased diet had commenced the fractures had united firmly.

The "katabolic" response to injury is thus conditioned not only by the injury itself but by some other unknown mechanism which may or may not involve the adrenal cortex. The fact that a mere increase in the corticosteroid output in the urine in normal uninjured persons produced by pituitary corticotrophic hormones is not associated with increased urinary nitrogen output suggests that increased adrenal activity alone cannot explain the "katabolic" response (Browne, 1943). In the debilitated person who has been injured increase in the protein input is not accompanied by increased nitrogen and corticosteroid outputs, which is precisely the reverse of the reaction of the normal individual. Browne *et al.* (1945), however, have reported two cases in which there had been loss of weight but which responded to increased nitrogen inputs by a typical "katabolic" reaction. Both patients died. It would appear that in them the mechanism which inhibited the "katabolic" reaction in the debilitated state was absent. In one of these cases the corticosteroid excretion was estimated and found to be of the same order as that of previously healthy severely damaged individuals.

In the "anabolic" phase which follows after the "katabolic" reaction the urine contains normal quantities of

the urinary corticosteroids and also of the 17-ketosteroids. The latter substances are derived in part from the adrenal cortex. Kochakian (1946) has shown that a 17-ketosteroid, presumably of adrenal origin, which has the power of conserving nitrogen can be isolated from the urine. This power is possessed by 17-ketosteroids of gonadal origin but is less pronounced in them. The magnitude of the positive nitrogen balance during the "anabolic" phase is not paralleled by the magnitude of the 17-ketosteroid excretion. It is independent of both the corticosteroid and 17-ketosteroid excretion. Testosterone propionate has been used with some success in increasing the positive nitrogen balance, but it has obvious disadvantages. It cannot in any way inhibit the "katabolic" response after injury in normal persons, but can increase the positive nitrogen balance after injury in debilitated individuals. The factors, other than the level of protein input, which influence the magnitude of the positive nitrogen balance in the "anabolic" phase are thus unknown.

Cuthbertson (1943) considered that the increased nitrogen loss after injury might result from the breakdown of protein molecules in an attempt to supply some component amino-acid of the protein molecules which was necessary for the repair process. If such an amino-acid formed, say, 3% of the protein molecule the remaining 97% of the molecule might be metabolized, as it could not be re-synthesized into protein in the absence of an essential part of the molecular structure. The nitrogenous portion (amino-N) of 97% of the protein molecule would be transformed into urea and excreted, leaving the carbon chains to be utilized for energy production or for storage as glycogen. Croft and Peters (1945) thought that in burns the organism might require extra methionine. They reasoned that if this were so then the addition of an adequate quantity of this amino-acid to the diet would satisfy the need and spare protein from being broken down to meet it. Their results suggested that methionine supplements reduced the nitrogen loss after burns. Unfortunately it has not been found possible to confirm their results in human patients subjected to injury or after burns. This, however, does not imply that Cuthbertson's original hypothesis is untenable. The amino-acid necessary for repair might be one of the other "essential" amino-acids of the protein molecule. Rose, Haines, and Johnson (1942, 1943) have shown that nitrogen equilibrium can be maintained in human subjects when all the input nitrogen is provided by ten "essential" amino-acids. If one of these amino-acids is removed from the daily input a negative nitrogen balance follows. Until it has been shown that supplements of these "essential" amino-acids do not reduce or abolish the negative nitrogen balance after injury or operation Cuthbertson's hypothesis remains as a possible explanation of the reason why a negative balance occurs. It does not, however, offer an explanation of how the body protein is broken down and the "essential" amino-acid rendered available.

The position at present is very unsatisfactory. A hypothesis which suggests that the negative nitrogen balance after injury is due to the demand for some component of the protein molecule, the remainder of the molecule being metabolized, is not proved. On the other hand a possible hormonal mechanism which on being brought into action inhibits protein synthesis and permits the de-amination of amino-acids to take place at an increased rate has not been proved to have a causal relationship to the "katabolic" response to injury. Thus both the "why" and "how" of the "katabolic" response are uncertain. The finding (Cuthbertson, Shaw, and Young, 1941) that injections of crude extracts of the anterior pituitary gland into animals

with experimental fractures prevented the usual weight loss and excessive nitrogen output is difficult to explain. It might have been expected that such injections would lead to increased activity of the adrenal cortex and presumably to an increased output of corticosteroid, with consequent inhibition of protein synthesis. Precisely the reverse occurred.

The same group of workers made the significant observation that skin wounds in experimental animals did not heal as rapidly as normal when crude extracts of anterior pituitary gland were injected. Now that relatively pure corticotrophic hormone from the pituitary gland is available these experiments require to be repeated and some attempt made to assay the urinary output of corticosteroid and 17-ketosteroids.

### Vitamin C and Injury

For some years past in most surgical clinics ascorbic acid (vitamin C) supplements of 200-500 mg. have been employed as a routine in the post-operative period and after injuries. Wolbach (1937) defined the function of the vitamin as being concerned with the production and maintenance of intercellular substances. Bourne (1944) showed that the tensile strength of healed wounds was increased when adequate quantities of the vitamin were provided in the diet. The demand for ascorbic acid is, however, much greater than might be expected were it to be used only at the site of injury. All the patients listed in Table I received daily supplements of 500 mg. of ascorbic acid from the day of operation or from the day after accidental injury for periods up to 25 days. During the first five days of administration no trace of ascorbic acid could be detected in the urine. In the second five-day period the operation cases were all excreting between 50 and 100 mg. of the vitamin on the 10th day. The vitamin was not excreted in the cases of accidental injury. During the third five-day period the ascorbic acid output of the operation cases had risen to between 176 and 234 mg. a day on the 15th day. No vitamin was detected in the cases of burns on this day. These cases were given supplements of 500 mg. for a further 10 days. On the 20th day the fracture cases were excreting more than 150 mg., but no ascorbic acid appeared in the cases of burns. These showed traces of the vitamin on the 23rd day, and on the 25th day excreted less than 100 mg.

Long (1947) has pointed out that when the adrenal cortex is thrown into activity by some physiological stress such as injuries or infections the ascorbic acid content of the cortex diminishes. In his article he has noted the work of Lowenstein and his colleagues, who have suggested that ascorbic acid is a necessary component of some of the active corticosteroids existing in the adrenal cortex. It is thus probable that some part of the increased demand for ascorbic acid after injury may come from the adrenal cortex. The relation of ascorbic acid to the "katabolic" response may be even closer than this statement implies. The vitamin in the presence of traces of copper is known to augment the activity of the enzyme arginase (Edlbacher and Leuthardt, 1933). As arginase is concerned with what appears to be the principal urea-producing mechanism in the liver (Krebs and Henseleit, 1932), the importance of this reinforcing action is apparent. Kochakian (1944) has found that after a period of undernourishment rats show a fall in the liver arginase of 52%. It is by no means certain that the local demand for the vitamins at the site of injury, the need for more ascorbic acid in the adrenal cortex, and an increased supply to the liver are sufficient to explain the large over-all requirements of the body for ascorbic acid after injury.

### Calcium Metabolism after Injury

It has been pointed out above that mere confinement to bed can produce a negative nitrogen balance. Reifensstein (1942) also showed that under like conditions the urinary calcium output may be doubled and the faecal calcium increased by one-third. In fracture cases the increased urinary calcium excretion reaches much higher levels. It then becomes a potential danger, for if conditions within the urinary apparatus are favourable the calcium may be precipitated as calcium phosphate and give rise to renal calculi. Shorr (1942) has shown that calcium excretion in the urine is balanced accurately in normal persons by the excretion of citrate. If enough of the latter ion is not available precipitation of calcium phosphate may occur. Investigations by Shorr and others have led to three possible methods for preventing calcium phosphate precipitation. The first is to use substances which can act as precursors of urinary citrate. No fully adequate material, however, has yet been found. The second method is to increase the output of urinary citrate by the use of oestrin; but such a method is not always desirable on account of other effects. The third method is to reduce urinary phosphate excretion by increasing faecal phosphate excretion. This Shorr (1943) accomplished by giving aluminium hydroxide by mouth. That substance forms an insoluble precipitate of aluminium phosphate in the bowel and leads to increased passage of phosphate into the bowel lumen. The value of these methods has not yet been fully explored.

### Summary

In well-nourished persons subjected to injury the urinary nitrogen output increases to reach a peak by the end of the first week after injury. This high output gradually declines until in less severe injuries it reaches the normal level by the end of two to three weeks. Thereafter the level of output may decline further, but by the end of two to three months it returns to normal. The high nitrogen output may be diminished but not abolished by high-protein diets during the first seven to ten days. Continuation of such diets, however, leads to a positive nitrogen balance during the latter half of the period of high urinary nitrogen output and during the subsequent period. In this way the depletion of body nitrogen is compensated. The magnitude of the nitrogen loss in the urine depends on the nutritional state of the individual and on the severity of the injury. Some of the loss is due to the effects of immobilization in bed, but this part is relatively small. Poorly nourished individuals show either no metabolic response or a diminished one after injury. There is evidence that the severity of the injury conditions the magnitude of the nitrogen loss in the urine. The source of the nitrogen lost in the urine during the period of high output is the body cells. These apparently can yield up protein without affecting their viability.

The mechanisms involved in these metabolic disturbances are unknown. It has been shown that the urine during the period of high nitrogen output contains large quantities of corticosteroid material presumably derived from the adrenal cortex. It is not certain how an increased output of such material is related to the increased urinary nitrogen output.

After injury the body requirement for ascorbic acid (vitamin C) is apparently greater. Some of the increased demand may be due to an increased utilization in the adrenal cortex and the liver and some to the needs of the tissues at the site of injury.

The increase in calcium output in the urine after injury is a potential danger, as insoluble calcium phosphate may be precipitated, leading to the formation of calculi. Various methods of treatment to avoid precipitation have been advocated, but these are still in the experimental stage.

I wish to thank the many surgeons who permitted observations to be made on their patients and the dietitians who co-operated in this work. My thanks are also due to Mrs. P. H. Herbert, Leverhulme Scholar, and to my technical staff—S. P. Steward, L. S. Drewell, and R. D. Chambers—for their assistance in the analytical

work. Dr. J. S. L. Browne has permitted me to quote freely from the reports of his group which have been recorded in the minutes of the Conference on Bone and Wound Healing.

## SYNCHRONOUS COMBINED TOTAL GASTRECTOMY

BY

J. BASIL HUME, M.S., F.R.C.S.

Surgeon, St. Bartholomew's Hospital and St. Andrew's Hospital,  
Dollis Hill

AND

GUY BLACKBURN, M.Chir.

Assistant Surgeon, Guy's Hospital and St. Andrew's Hospital,  
Dollis Hill

Since the introduction of transthoracic total gastrectomy in 1938 there has been an appreciable improvement in the results of surgery in carcinoma of the stomach. The work, among others, of Churchill, Sweet, Garlock, and Phemister testifies to this admirably and has altered the whole outlook, but even now the figures leave a good deal to be desired. The five-year cure rate is depressingly low, though it is early to assess it, and the mortality rate far too high. Finney and Rienhoff (1929) quoted a 53.8% mortality in 67 cases, Waugh and Fahlund (1945) 44.2% in 77 cases, and Clagett (1945) 16.6% (five deaths in 30 operable cases of malignant disease of the stomach). These figures illustrate the progressive improvement in surgical treatment of an otherwise fatal disease, and a great many factors are responsible—earlier diagnosis, better pre-operative preparation, an increasing resectability rate, advances in anaesthesia, and the introduction of chemotherapy and antibiotics.

This communication is essentially a preliminary one, recording a new method of approach which we have found useful, and clearly some time must elapse before any instructive figures are available or there are results from which deductions can be drawn.

FIG. 1.—Diagram showing position of personnel and apparatus during operation.

In an attempt to reduce the time of operation we conceived the idea of two surgeons working synchronously, in a manner parallel to that employed in excision of the rectum (Morgan and Lloyd Davies). The position of the patient on the table has therefore been adjusted to make it possible for one surgeon to work in the chest at the same time as the other works in the abdomen (Fig. 1). A tilt of approximately 30 degrees (Fig. 2) has made this feasible, and it has been found easier for the abdominal surgeon to sit down and work through a transverse incision. This divides the left rectus muscle and just crosses the midline. Each surgeon has his assistant opposite him, though we have tried the alternative of having the assistant on the same side of the table. A Mayo table is placed at the head of the table and another at the foot, and an instrument trolley is provided for each of the two sisters; thus confusion or competition in the use of instruments is avoided. Finally, we pay particular attention to the position of the arms, avoiding the use of an arm rest, which was found to impede the thoracic surgeon. The illumination of the two wounds presents no difficulties provided that separate lights are employed. Additional spotlights can be used on either side if required.

The usual thoracotomy incision, with resection of one rib, has been made to approach the lower oesophagus, but we have not found it necessary to cut across the costal margin and join the thoracic and abdominal wounds. Experience of thoraco-abdominal wounds with and without damage to the costal margin has

convinced us that its division is not only unnecessary for exposure but undesirable for the patient's convalescence. The thoraco-abdominal wound employed by surgeons such as Wookey and Tanner is therefore replaced by a thoracic and an abdominal wound separated by the width of the costal margin.

The lymphatic drainage of the stomach is so disposed (Fig. 3) that excision of the cardia and 2-3 cm. of oesophagus is essential if ablation of a growth is to be radical. Submucosal spread in the oesophagus and even enlarged lymph glands above the diaphragm occur often enough to commend this step. It is, moreover, an abnegation of surgical principles to remove only part of the lymphatic field in a disease so fatal as carcinoma of the stomach. We would go even further and say that the operation of partial gastrectomy for carcinoma of the stomach is lamentably conceived as a radical method of extirpation of malignant disease in this area. It should surely be replaced by total gastrectomy if and when this operation can be done with a comparable mortality.

Division of the jejunum and end-to-end or end-to-side oesophago-jejunostomy have been carried out, with an anastomosis of the Roux type to complete the operation but these are details outside the scope of our present theme. Jejunostomy likewise seems to be a matter of individual preference, adaptable to certain patients but not invariably required.

The time of operation should, in our view, be two to two and a half hours in an uncomplicated case—the abdominal surgeon doing the division of the duodenum, lower stomach mobilization, and Roux anastomosis, and the thoracic operator the mobilization of oesophagus and cardia and the oesophago-jejunostomy. It is pertinent to add that the thoracic operator does not begin until operability in the abdomen has been decided by his colleague.

FIG. 2.—Tilt of the table.

FIG. 3.—The disposition of lymphatic drainage of stomach.

We believe this to be easier than abdominal total gastrectomy as practised by Lahey and others. Decrease in the time of anaesthesia alone would seem to justify it, because patients with this disease tolerate anaesthesia badly. Our preference is for inhalational anaesthesia with endotracheal intubation, and, if controlled respiration is employed the lung should be inflated at half-hourly intervals to minimize the risk of post-operative collapse. Bronchoscopy at the end of operation may in some instances be a wide additional measure.

### Conclusions

The present position of surgery in relation to carcinoma of the stomach is unsatisfactory.

Immediate mortality from total gastrectomy for malignant disease is too high.

A reduction in the time of operation might help to reduce morbidity and mortality.

Synchronous combined excision through a thoracic and an abdominal wound is suggested as a means of attaining it.

We are indebted to Dr. John Hunter for his skill and care in anaesthetizing the patients, and to the staff of St. Andrew's Hospital, Dollis Hill, for much valuable help.

## EFFECT OF PENICILLIN ON BACTERIAL FLORA OF THE MOUTH

BY

DAVID A. LONG, M.D.

Lecturer in Bacteriology, London School of Hygiene and Tropical Medicine

Many of the organisms present in the mouth as part of the normal flora or as pathogens have been known, since Fleming's original paper in 1929, to be penicillin-sensitive, but it was not until 1944 that the possibility of treating oral infections with penicillin was fully appreciated. Basing his observations on the bacteriological findings in a series of patients treated by Mowlem (1944) for infection of the mandible, Garrod wrote:

"The great majority of the very numerous bacterial species found in the mouth are penicillin-sensitive. This is of far-reaching practical importance, since it means that infections derived from or connected with the mouth are in general susceptible to penicillin treatment, just as those connected with the bowel are insusceptible owing to the prevalence there of resistant species. The flora of the mouth is highly complex and has been imperfectly studied; the following observations are therefore perforce of an elementary nature. In plates, both aerobic and anaerobic, inoculated with material from osteomyelitis of the jaw, from infected compound fractures of the jaw, and from infected gums, or with saliva, the only organisms ever found markedly resistant to penicillin as judged by the cup method have been *Monilia albicans*, an occasional *Neisseria*, and *Haemophilus*. Whole groups of bacteria which are thus sensitive in doubtless varying but apparently adequate degrees are aerobic streptococci (including various types of *Str. viridans*), anaerobic streptococci, anaerobic Gram-negative bacilli (*F. fusiformis* and many others unidentified), and various Gram-

positive bacilli. The mixed and predominantly anaerobic flora often found in infections derived from the mouth is thus in general sensitive to penicillin, and the results of treatment are as would be expected from this."

These findings were confirmed by MacGregor and Long (1944, 1945a), who incorporated penicillin in a slowly dissolving pastille for use in the mouth; the patient was instructed to insert another when the previous one had disappeared. By this means the saliva could be kept fully bacteriostatic throughout the day. Promising results were obtained in a variety of infectious conditions of the oral cavity and in prophylaxis against infection secondary to surgical or dental trauma in the mouth.

Since then penicillin has been applied to the mouth by numerous workers, using many different techniques; the whole subject has recently been reviewed by Hutchinson and Cranston Low (1946). It is not proposed to discuss these various techniques, but to describe the bacteriological findings in a series of patients who were treated with penicillin during the years 1944-6. These patients were classified as follows:

**A. Patients Receiving Local Penicillin Treatment** (Penicillin Pastilles).—(1) Patients with acute gingivo-stomatitis (Vincent's type); (2) patients with acute and chronic tonsillitis; (3) patients under the care of the Maxillo-facial and Plastic Units at Hill End Hospital, St. Albans, while receiving treatment for a variety of traumatic, surgical, and dental conditions. The total number of cases was 500.

**B. Patients Receiving Systemic Penicillin Treatment.**—(1) In a dosage of 500,000 to 1,000,000 units of penicillin in 24 hours:—(a) Patients treated under the scheme sponsored by the Penicillin Trials Committee of the Medical Research Council for the investigation of the penicillin treatment of subacute bacterial endocarditis; (b) patients treated for severe diphtheria and scarlet fever; (c) patients treated for actinomycosis. The total number of cases in Group B 1 was 30. (2) In a dosage of less than 500,000 units of penicillin in 24 hours:—(a) As Group B 1 (a); (b) patients receiving routine penicillin treatment for a variety of conditions. The total number of cases in Group B 2 was 30.

### Excretion of Penicillin in the Saliva

Changes can be produced in the bacterial flora of the mouth by the administration of penicillin either locally as already stated (Garrod, 1944; MacGregor and Long, 1944) or systemically if sufficiently large dosage is employed (Long, 1946a, 1946b, 1947). It is probable that in the latter case the changes are caused by penicillin excreted in the saliva, though attempts to demonstrate this have either been unsuccessful (Rammelkamp and Keefer, 1943) or have detected it only in small quantities (Florey *et al.*, 1941; Struble and Bellows, 1944; Fleming, 1945). No simple relationship has been shown to exist between the penicillin content of the saliva and the penicillin content of the blood. Herrell (1945), reviewing the evidence, is unable to be dogmatic, and states: "I am inclined to believe that fairly adequate amounts of penicillin do reach the saliva following systemic administration." The persistence of highly penicillin-sensitive organisms in the mouth of patients receiving less than 500,000 units of penicillin systemically in 24 hours, combined with failure to demonstrate penicillin in their saliva, suggests that the threshold for penicillin excretion in the saliva is attained only by a dosage of this magnitude. However large the dosage employed systemically, penicillin will be demonstrable in the saliva only in the initial phases of treatment, for as soon as the organisms of the *Bacterium* group establish themselves in the mouth penicillinase is produced in sufficient quantity to destroy it. Further work on the concentration of penicillin in the blood, the excretion of penicillin in the

saliva, and the changes produced in the flora of the mouth at a given time will possibly clarify the position.

### Changes in Flora of the Mouth

Whether penicillin is administered locally, or systemically in the dosage stated, the changes produced in the bacterial flora in the mouth are the same, but with systemic administration the flora of the tonsils, pharynx, and nose is also affected. Moreover, the action can be maintained throughout the 24 hours, whereas with the local method of treatment continuous action depends on the conscious co-operation of the patient.

After the administration of penicillin by either route there was a rapid fall in the number of viable penicillin-sensitive organisms present in the mouth. The changes appeared first in the saliva, in which the total viable count fell from about 60,000,000 organisms per ml. to about 8,000,000 organisms per ml. in a few minutes (MacGregor and Long, 1945b). Changes in the bacterial flora of the gum pockets and superficial parts of the tonsils followed in a few hours, and were more striking when the systemic method of administration was employed. Since the nose is the main source of droplet spread of haemolytic streptococci (Hamburger and Green, 1946) the systemic action of penicillin in rendering patients non-infectious is very important. The suggestions that penicillin pastilles might replace the use of surgical masks (Fleming, 1945) and render carriers of haemolytic streptococci non-infectious (MacGregor and Long, 1944) are no longer tenable.

The use of systemic penicillin in large dosage in the treatment of nasopharyngeal diphtheria has been discussed elsewhere (Long, 1947). Initial experiments on carriers of haemolytic streptococci and diphtheria bacilli show that this kind of treatment is the most effective known. Cultures from excised tonsils indicated that the flora of the crypts remained unaltered by penicillin pastilles, but the effect of massive systemic dosage is not known, since none of the patients so treated had their tonsils removed. It is important to discover the effect of such therapy on the tonsillar crypt flora for other reasons also. For instance, such treatment may be of value in haemolytic streptococcal infections in patients suffering from rheumatic fever and other ailments associated with infected tonsillar crypts.

During the first few days of treatment *Haemophilus influenzae*, *Neisseria pharyngis sicca*, and *Monilia albicans* were the only organisms demonstrated in cultures made from material taken from the oral cavity. Such cultures often remained sterile.

This first phase of rapid reduction of organisms was followed by a second phase of bacterial invasion by organisms of the *Bacterium* group. Of 312 patients suffering from acute gingivo-stomatitis (Vincent's type) treated with penicillin pastilles in collaboration with Dr. A. B. MacGregor, 77% became infected by Gram-negative bacilli between the second and seventh days of treatment. Had all the patients been fully co-operative and sucked their pastilles regularly it is probable that the figure would have been higher. It was noted that conscientious patients often became infected with Gram-negative bacilli earlier than did the careless ones. All patients receiving systemic penicillin in a dosage of a million units a day for more than three days developed a secondary bacillary infection, most of them on the third to fourth day of treatment, whether penicillin was administered locally or systemically. Once present the invading organisms rapidly increased in numbers until the total viable count in the saliva was about 60,000,000 per ml. On stopping treatment they gradually decreased in numbers as the normal flora re-established

itself. Gram-negative bacilli did not produce penicillin stomatitis, but were associated with a breakdown in intra-oral surgery with destruction of skin- and bone-grafts. Mowlem (1945) states that "penicillin pastilles may lead to the appearance of extraneous organisms which are not penicillin-sensitive and the presence of which is more disastrous than is that of the normal flora of the mouth." Protected by the penicillinase produced by these organisms, the flora of the mouth present before treatment partly returns. Thus in a patient with a very severe acute gingivo-stomatitis secondary to metal poisoning, who was never cured by penicillin pastilles, organisms of the *Bacterium* group always established themselves before the pathogenic organisms could be eliminated. Nowadays, with penicillin freely available, all penicillin-sensitive organisms could probably be eliminated from the lesions of such patients by massive systemic dosage before the organisms of the *Bacterium* group became established.

Three hundred strains of various species of Gram-negative bacilli isolated from the patients already mentioned were classified as follows:—

<i>Bact. aerogenes</i> , Type I ..	40%	<i>Intermediate</i> , Type II ..	4%
<i>Bact. coli</i> , Type I ..	17%	<i>Bact. aerogenes</i> , Type II ..	10%
<i>Intermediate</i> , Type I ..	14%	Irregular other types ..	16%
<i>Bact. coli</i> , Type II ..	4%	<i>Pseudomonas pyocyanea</i> ..	4%

As the majority were of non-faecal type it is probable that they were derived from food or water.

### Behaviour of Certain Mouth Micro-organisms

Ordinary strains of *H. influenzae* are penicillin-resistant, but it is interesting to note that the haemolytic variety, which on a blood-agar plate may often be mistaken for a haemolytic streptococcus, is remarkably sensitive and is rapidly removed from the mouth by penicillin treatment.

The effect of penicillin on *Actinomyces bovis* is also peculiar. Marked changes in the morphology of this organism, with loss of its characteristic dimorphism and a tendency to assume the bacillary form, were associated with atypical colony formation which rendered identification difficult once treatment had been started.

### Summary

Changes in the flora of the mouth were studied in 500 patients treated by the administration of penicillin locally in small dosage by pastilles, and in 60 patients treated systemically with penicillin given by intramuscular injection.

Penicillin-sensitive organisms were eliminated from the surface of the tonsils and from the nose and pharynx, as well as from the mouth, by systemic administration in large dosage (approximately one million units a day). Patients were thereby rendered non-infectious.

The changes in the flora of the mouth are divided into an initial phase of reduction of the penicillin-sensitive organisms of the mouth and a later phase of invasion by Gram-negative bacilli. The practical consequences of these changes are discussed.

Penicillin excretion in the saliva probably occurs only when a dosage of over 500,000 units in 24 hours is employed. It will be demonstrable only during the initial phase of reduction of bacteria, before the organisms of the *Bacterium* group have established themselves.

Three hundred strains of secondary invading organisms were classified.

It is a pleasure to acknowledge the helpful criticism of P. L. P. Garrod, in whose laboratory this work was undertaken. Most of the observations made are based on work carried out by Dr. A. B. MacGregor on the administration of penicillin in the form of pastilles. I am indebted to the staff of St. Bartholomew's Hospital and to Mr. Rainsford Mowlem, director of the Maxillo-facial

Plastic Units at Hill End Hospital, St. Albans, for their co-operation and for providing much of the clinical material.

## CALCULATION OF TUXFORD'S INDEX BY GRAPHICAL METHODS

BY

H. CAMPBELL, B.A., F.S.S.

(From the Nuffield Department of Industrial Health, University of Durham, King's College, Newcastle-upon-Tyne)

**Q.**—In a large series of cases the calculation of Tuxford's index of nutrition in childhood is laborious and time-consuming. Is it possible to devise a graph from which the index may be rapidly computed?

Tuxford's (1939) index of nutrition in male children is given by the formula:

$$T = \frac{W}{H} \times \frac{379 - m}{0.3} \quad (\text{Equation 1})$$

where  $W$ =weight in lb.,  $H$ =height in inches, and  $m$ =age in months.

The normal level of the index, according to Tuxford's data, which were based on 584,000 measurements made in 1909-10, is 1,000. Although this is naturally an arbitrary figure it is contended that the index does provide some basis for a comparison between different groups of children and between different stages of development among the

same children when a clinical examination is not possible. The validity of this assumption was tested extensively against clinical examination by Huws Jones (1938).

The calculation of the index for a large number of cases is laborious, and although a graphical method of calculation was indicated in the original paper it is not simple to use.

The original formula can be arranged as follows:

$$y = \frac{W}{H} \quad (\text{Equation 2}) \quad \text{and} \quad y = \frac{0.3T}{379 - m} \quad (\text{Equation 3})$$

It should be noted that " $y$ " is an algebraic expression which is needed only for the construction of graphs and is not calculated in any individual case.

### Construction and Use of the Graphs

Equations 2 and 3 can now be graphed separately. In the case of Equation 2, if  $y$  is the vertical axis and  $W$  the horizontal axis, then for one given fixed value of  $H$  there is a diagonal line which will fix all values for  $y$  and  $W$ . Consequently by drawing a series of diagonal lines, like contours, for each value of  $H$  from say 18 to 66 in. it is possible to cover all appropriate values of  $W$ ,  $y$ , and  $H$ . The simplest way to construct this graph is to notice that along the horizontal line  $y=1.0$ ,  $W=H$ , so the exact points for  $W$  for each height can be fixed—e.g.,  $H=20$  in.,

$W=20$  lb. Similarly along the line  $y=1.5$ ,  $W=\frac{3}{2}H$ , so the exact points of  $W$  can again be fixed—e.g.,  $H=20$  in.,  $W=30$  lb. These points can then be joined by straight lines and extended if necessary. A skeleton of this is outlined in Graph 1.

In the case of Equation 3, again make  $y$  the vertical axis on exactly the same scale as before, only this time tabulate it on the right-hand side of the graph. If  $T$  is the horizontal scale moving from right to left, then, as before, a series of contours for each fixed level of  $m$  can be drawn which will be straight lines. The simplest method of drawing these is to take the two vertical lines  $T=1,000$  and  $T=900$ , where  $y$  will be  $\frac{300}{379 - m}$  and  $\frac{270}{379 - m}$  respectively. This gives two points for each value of  $m$ , and thus the corresponding contour line will be fixed uniquely—e.g.,  $m=0$  and  $T=1,000$ , then  $y=0.792$ , and when  $m=0$  and  $T=900$ , then  $y=0.712$ . The line joining these two points gives the contour for age at birth. This is illustrated in Graph 2. Graphs 1 and 2 may now be placed side by side so that the vertical axes coincide.

If it is proposed to use a separate index for females as suggested by Tuxford it will be necessary to construct an alternative Graph 2 from the formula:

$$y = \frac{0.27T}{355 - m} \quad (\text{Equation 4})$$

As previously, all the contours are straight lines which can be readily constructed by marking the two points where each line cuts the two vertical lines  $T=1,000$  and  $T=900$ .

**Use of the Graphs.**—On Graph 1 measure off the weight of the child along the horizontal axis and the height along a diagonal contour; these will give a fixed point. Place a ruler horizontally through this point, move along the ruler on to Graph 2 until it cuts the appropriate age contour on this second graph, then move vertically downwards on to the  $T$  scale; this will fix the index of nutrition. An alternative method would

Tuxford's index of nutrition in childhood. Specimen chart: Weight 56 lb., height 50 in., age 120 months; index 967.

be to engrave Graph 2 on a transparent substance such as mica or celluloid, which could then be moved over the first graph until the age contour coincides with the appropriate point on Graph 1.

### Accuracy of the Result

The accuracy of the result depends entirely upon the size of the scales and the skill of the draughtsmanship used in their construction. The best scales on ordinary 1/10-in. squared paper would probably be:

for  $y$  from 0.7  $y$  to 1.5  $y=16$  in.  
for  $W$  from 0 to 100=10 in.  
for  $T$  from 900 to 1,100=10 in.

The height contours can then be drawn for every inch in height from 18 to 66 in. and the age contours for every 3 months from 0 to 168 months. In these conditions it will be possible to determine  $T$  accurately to the nearest unit.

To demonstrate the use of the graphs an illustrative chart is given. Start with weight 56 lb., move vertically upwards till this line cuts the contour for height 50 in., then move horizontally to the left until the contour for age 120 months is cut on Graph 2, then vertically downwards on to the scale for the index, which reads  $T=967$ .

## Medical Memoranda

### Spontaneous Delivery of Placenta in Front of Foetus without Haemorrhage

Spontaneous delivery of a placenta in front of the foetus is a rare happening, and for it to occur without haemorrhage is very rare indeed.

#### CASE REPORT

The patient, a 7-gravida aged 43, was admitted to hospital under the care of Prof. Hilda Lloyd on May 24, 1947, as an emergency case with a prolapsed cord. Her last menstrual period began on Sept. 12, 1946, she was thus 37 weeks pregnant. She had no abnormal symptoms during this pregnancy, and was reported as having been normal before the onset of labour. Her six previous pregnancies included four normal ones and two breech presentations, both of the latter ending in stillbirths.

She stated that pains had started at 5.30 o'clock that evening, "waters breaking" two hours later with the escape of a "moderate" amount of blood-stained liquor. She was quite definite that it was "blood-stained water" and not pure blood. She stated that the cord first appeared at the vulva shortly after this, and she then (and only then) sent for her nurse, who promptly summoned the doctor.

On admission at 9.45 p.m. her general condition was good, temperature 98.2° F (36.8° C.), pulse 100, and B.P. 134/88. The urine contained no albumin, sugar, or acetone. There was no clinical anaemia. Abdominal examination showed the foetus to be lying obliquely, with the head in the right iliac fossa. She was having good contractions, one every three minutes, but the presenting part was not fixed. The foetus was a small one. No foetal heart could be heard. Inspection of the vulva showed a protruding loop of umbilical cord, involving about 6 in. (15 cm.), lying outside the vulva.

The patient was anaesthetized with thiopentone and gas, oxygen, and ether, and placed in the lithotomy position. After thorough disinfection of the vulva and prolapsed loop of cord, which was not pulsating, a hand was inserted into the vagina, and the placenta was encountered lying free but without any membrane attached. It was now obvious that the foetus must be dead; the placenta was removed, and the cord excised generously to minimize the risk of carrying infection upwards during the subsequent manoeuvres. The cervix was dilated between three and four fingerbreadths, soft, and pink. The presentation was a shoulder with the back anterior.

In view of the retention of membranes and the small dead foetus, immediate delivery was decided on. After internal version had been performed a leg was brought down, and gentle traction was exerted on the half-breech. The other leg was then brought down and the foetus delivered without difficulty as far as the waist. Both arms were extended and were now brought down. The body was then allowed to hang for two or three minutes by its own weight, after the manner of Burns. At the end of this time the cervix still gripped the head firmly, so the skull was perforated through the mastoid region, delivery then being completed without difficulty. There was no abnormal bleeding. Ergometrine 0.5 mg., was given intravenously, and the retained membrane was removed with forceps. Again there was no unusual loss. The cervix and lower uterine segment were carefully examined, but were found to be undamaged. The patient was given 100,000 units of penicillin immediately, and a total of 500,000 during the next twenty-four hours, as a prophylactic, systemically. The puerperium was entirely afebrile, and was normal in every respect.

The foetus (with perforated skull) weighed 3 lb. (1.36 kg.), and was a male with a marked degree of hypospadias and double hare-lip. It revealed no sign of maceration. The placenta showed no gross abnormality, was normal in size, and weighed 11 oz. (310 g.)—a weight in proportion to the weight of the foetus.

### COMMENT

It is suggested that the possible mechanism was that the placenta had a poor attachment, becoming detached with the onset of pains, and that the uterine contractions, possibly assisted by a mild degree of hydramnios (a not unreasonable assumption in view of the foetal abnormalities), drove the presenting part down and plugged the placental area. If it was partly or largely on the anterior surface of the lower segment the foetal back was ideally placed for the purpose.

The assumption that the placenta was attached to the lower segment seems to be the only possible explanation that covers the three facts of primary placental separation, retention of membranes completely, and absence of haemorrhage.

My thanks are due to Prof. Hilda Lloyd for permission to publish this case, and to Mr. Hugh McLaren, First Assistant to the University of Birmingham Gynaecological and Obstetric Unit, for his advice and encouragement.

M. HALDEN LLOYD, M.B., Ch.B.,  
Late House-Surgeon, Birmingham Maternity Hospital.

### Suturing the Fractured Olecranon

For those who prefer simple suture to the use of wire or screw for the fractured olecranon the following method may be found useful in overcoming the difficulty of tying sutures tightly enough to give perfect fixation.

The fragments are drilled transversely. Two sutures are passed through the drill holes in opposite directions and tied as tightly as possible. The knots then lie one on each side of

the bone. One end of each suture is left long (Fig. 1). These long ends are passed across the bone and with the aid of an aneurysm needle are threaded under the sutures on the opposite side (Fig. 2). They are then tied together tightly across the bone, thus greatly increasing the tension of the sutures and incidentally holding down the spur of bone commonly found on the upper fragment due to the oblique direction of the fracture (Fig. 3).

The principle is of course in common use at sea and for lashing loads on railway trucks and lorries.

T. J. FAIRBANK, F.R.C.S.

## Reviews

### A FOUNDATION OF NEUROLOGY

*The Integrative Action of the Nervous System.* By Sir Charles Sherrington, O.M. Second edition, entirely reset. With a new foreword by the author. (Pp. 433. 25s.) Cambridge: The University Press. 1947.

It was indeed an inspiration that moved the Physiological Society to have a new edition of Sherrington's *Integrative Action of the Nervous System* issued on the occasion of the recent International Physiological Congress at Oxford. In doing so they have honoured not only the author but also the British school of physiology, which owes so much to him, and they have recreated the stimulus this imperishable work gave to physiologists forty years ago. I have called it "an imperishable work," for it is one of those works, rare in science, the permanent value of which is unquestionable, and I believe that future generations of physiologists will so acclaim it. In physiology it holds a position similar to that of Newton's *Principia* in physics, and when physiologists finally emerge from that preoccupation with technologies under which the present generation staggers, and when they find time and the inclination to contemplate and interpret the innumerable observations now being accumulated in such unresting haste, the full stature of this book and the permanent quality of its author's teaching will become apparent. For it is more than an orderly record of precise observations: it is a product of sustained thought upon what is essentially—though only his genius revealed it as such—a single problem—namely, the mode of nervous action. Sherrington advances the argument step by step, exposing the full significance of each new aspect of the problem as he brings it to light. Here is no medley of *ad hoc* hypotheses but a logical analysis and synthesis bearing the imprint of scientific genius.

A detailed account of the *Integrative Action* is not necessary here or possible in a brief notice, but the principles of reflex action that he expounded will remain essential foundations of whatever edifice of knowledge may yet be erected upon them. The book is a primer for every physiologist and student of clinical neurology—indeed, for every medical man who values the study of precise observation and its integration into ordered knowledge as part of a scientific training.

To-day the thoughts and affection of all his pupils and admirers go out to Sir Charles Sherrington, and they recall with gratitude the inspiration he has been to them and the generous and ready help he was always so willing to afford them. They will welcome the new edition of this book and will see in it a good omen for the future of physiology.

F. M. R. WALSH.

### ANOTHER HEREDITARY DISEASE

*Heredopathia Atactica Polyneuritiformis. A Familial Syndrome not Hitherto Described.* By Sigvald Refsum. (Pp. 303: 28 figures. No price given.) Oslo: Johan Grundt Tanum Forlag.

The author of this monograph gives a detailed history of five cases of "a familial syndrome not hitherto described" seen in three sibships of two unrelated families. The condition is of considerable interest, and it is always something of an event to hear of yet another hereditary disease. A recessive gene seems to be the cause of the disease in all cases. As is to be expected in so rare a manifestation, the malady has occurred in each case in the offspring of consanguineous parents who showed no sign of a similar affection.

The ages of the patients at the date of observation were 41, 32, 23, 38, and 32 years. Signs of disease had appeared some years before, but in no case had serious incapacity previously occurred. The main characteristic signs include (a) night-blindness, with loss of the peripheral fields of vision and fundal changes—not, however, typical of retinitis pigmentosa; (b) difficulty in walking, noted at the ages of 36, 28, 20, 37, and 32 respectively; (c) "polyneuritis-like manifestations" associated with muscular wasting, ataxia, and sensory disturbances. The author discusses the relationship of the cases to retinitis pigmentosa, Charcot-Marie-Tooth's disease, and hereditary ataxia,

to none of which conditions in its typical form does the condition appear to approximate. As an addendum to the monograph he describes necropsies on two of the patients who died suddenly. Distinct pigmentation of the nerve cells in all sections of the brain, and marked disturbances in the lipid and probably in the protein metabolism, were found. The pathologist, Dr. Cammermeyer, concluded that the disease belongs to the lipidoses and is closely related to Niemann-Pick's disease and to familial amaurotic idiocy.

Though this volume presents facts of great interest, it might with advantage have been shortened by the omission of a good deal of discussion, much of it shown by the post-mortem findings to be irrelevant.

JULIA BELL.

### RECENT NEUROLOGY

*The 1946 Year Book of Neurology, Psychiatry and Neurosurgery.* Neurology: edited by Hans H. Reese, M.D., and Mabel G. Masten, M.D. Psychiatry: edited by Nolan D. C. Lewis, M.D. Neurosurgery: edited by Percival Bailey, M.D. (Pp. 732; illustrated. 53.75 or 21s.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

The series of *Year Books* is a welcome annual addition to one's professional library. Since 1945 some of the subjects have been redistributed, and neurology now accompanies psychiatry and neurosurgery, while endocrinology is consigned with metabolism and nutrition to another volume. This little book is an interesting and useful guide to the current literature—perhaps we should say to current American literature, for there is a tendency to emphasize unduly the work of local writers. Indeed the editors of the neurological section confess in their introduction that "the clinical material from foreign countries has been abstracted only with regard to its obvious importance, since too much of it reviews old material." Rather than take umbrage at any fancied neglect, we in Britain might act on the hint, produce a greater output of original work, and look to the present rather than the past.

The *Year Book* series compares, of course, with its older cousin, the *Medical Annual*. There are differences in the scheme of presentation. In the British work contributors more often take as their unit a subject rather than an author's individual communication and make *en courant* comments and criticisms, while the American *Year Book* consists of abstracts of original articles, with editorial remarks appended in small print. Both methods have their advantages, but the *Year Book* may well be said to appeal less to the medical practitioner than to the embryo specialist.

MACDONALD CRITCHLEY.

### WHY AND HOW

*Man: The Verdict of Science. Science and Superstition.* By G. N. Ridley. The Thinker's Library, No. 114. (Pp. 156. 2s. 6d.) London: Watts and Co. 1946.

This book is a succinct and clearly written account of anthropology, if we use that term with its widest connotation. Mr. Ridley does not try to disguise his own opinions but honestly seeks to epitomize fairly the opinions of others. The publisher's "blurb" is truthful in saying that "the result is a book which will be found stimulating reading, even by those whose philosophy impels them to disagree with Mr. Ridley's conclusions." Even theologians, with whom Mr. Ridley is not in charity, are not likely to be irritated, for his "philosophy" is very naive. For instance, we read on p. 10 (a typical passage):

"A long time ago marriage between members of a family was observed to produce frequently abnormal offspring, and these were regarded as a sign of God's displeasure at the practice. It therefore became illegal in the eyes of the Church and the State for near relatives to mate. When, many centuries later, science had devised methods by which to study how children inherited their characteristics from their parents, the whole matter was put on an entirely new foundation—a foundation of fact that effectively removed it from association with the irrational beliefs that people had formerly entertained concerning God's feelings on the subject."

As Karl Pearson (by no means a lover of theology) used to say. Science is concerned not with the question Why? but with the question How? Those who believe in a divine order may be mistaken in their answer to the question why

things are as they are. To show how inbreeding may produce bad results does not, and indeed ought not, to shake their belief. The father of vital statistics, John Graunt, noted that although more males than females were born more died before puberty, and so, as he said, "Every woman may have an husband, without the allowance of polygamy." Contemporary theologians were delighted by this demonstration of how God, who in their opinion disapproved of polygamy, had made it unnecessary. Mr. Ridley is, like Laplace in the anecdote, quite entitled to say that he has no need of the hypothesis of God, but he should not misrepresent it.

Mr. Ridley's section on psychology is useful, but a paragraph on Aristotle's psychology would have improved it. Not only did the Aristotelian definition of the soul as the realization, the entelechy, of the body have an immense influence on subsequent thought, but his discussion brings out the essential difficulty of any hypothesis which in a scientific sense describes, not explains, the soul-body relation. The name of Berkeley does not appear in the "Reading Guide" or in the text, which is a pity. The three dialogues between Hylas and Philonous are not likely to convince materialists that "matter" is impossible, but it is always wise to hear what can be said against one's beliefs when it is said in such good English. T. H. Huxley did not agree with Berkeley, but he admired him.

M. GREENWOOD.

### A GREAT REFORMER

*No Centenario de Pestalozzi.* Monografia No. 4 do Boletim do Instituto de António Aurélio da Costa Ferreira. (Pp. 61. No price given.) Lisbon.

This monograph was dedicated by the António Aurélio da Costa Ferreira Institute in Lisbon to the memory of Johann Heinrich Pestalozzi, the Swiss educational reformer, on the second centenary of his birth. In it Prof. D. Santos discusses this great humanitarian's message for a generation confronted with nearly 32 million child victims of war. He gives a brief account of Pestalozzi's poverty-stricken childhood, the influences—especially that of Rousseau—that moulded his character and inspired his life's work, and its full flowering in 1798 when he came to the relief of children orphaned through the French invasion of Switzerland. Santos discusses his subsequent educational experiments and his numerous publications. Pestalozzi strove to attain an educational system that would permit a psychological approach to the individual, directing his harmonious development and spiritual regeneration, and he aimed also at making human labour an ennobling influence. Santos calls for a revival of his ideals in an age when technical studies and the memorizing of facts dominate education. He calls for schools which will be "a nursery of men and not factories of automata." Child psychologists, magistrates of juvenile courts, and social workers will endorse his views.

The monograph also contains appreciations of Pestalozzi by two graduates of the University of Lisbon. One illustrates from Pestalozzi's writings the role of the mother in education and of the woman in society, and analyses his educational system; the second describes his personality and work. Of topical interest is the article by W. R. Corti (reprinted from *Pro Juventute*) which completes the monograph. He describes the village of Pestalozzi—the child settlement which is being established at Trogen, in Switzerland. Inspired by Pestalozzi's example in 1798, it offers shelter and family life to the disinherited orphans of the war and aims at preserving their national qualities in an international medium. Corti outlines the magnitude of the problem and urges the need for this example to be followed in all countries.

J. J. KEEVIL.

*The Care of Babies and Young Children in the Tropics* is an admirable pamphlet written by Dr. John Gibbens and obtainable from the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality, 5, Tavistock Place, London, W.C.1 (price 1s.). Dr. Gibbens gives a simple account of elementary measures to be taken against infectious diseases in the Tropics, detailed instructions for feeding the baby on breast milk or artificially, and includes advice on inoculation, suitable clothing, and care of the skin.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Adrenalin-free Cyclic Anesthesia.* By Béla Mezö, M.D. (Pp. 40. No price.) Budapest: Printing House Frater. 1946.

The author describes his method of inducing analgesia by infiltrating the sympathetic ganglia with adrenaline-free "pantocaine."

*A Synopsis of Hygiene (Jameson and Parkinson).* By G. S. Parkinson, C.B.E., D.S.O., M.R.C.S., L.R.C.P., D.P.H., and K. M. Shaw, M.B.E. 9th ed. (Pp. 791. 28s.) London: J. and A. Churchill. 1947.

A textbook of public health and hygiene, with an account of the relevant laws.

*Essentials for Final Examinations in Medicine.* By John de Swiet, M.D., M.R.C.P. 3rd. ed. (Pp. 178. 9s.) London: J. and A. Churchill. 1947.

Intended to aid rapid revision before taking the "finals."

*Practical Points in Penicillin Treatment.* By G. E. Beaumont, D.M., F.R.C.P., and K. N. V. Palmer, M.B., M.R.C.P. 2nd ed. (Pp. 18. 1s. 6d.) London: J. and A. Churchill. 1947.

Notes on the organisms sensitive and insensitive to penicillin, the diseases for which it is suitable, and methods of administration.

*Disfunciones Motoras del Estómago.* By E. Arias Vallejo (Pp. 155. No price.) Madrid. 1947.

A monograph on functional disorders of the stomach and intestines.

*Renewal Pages for Nelson Loose-Leaf Surgery.* New York and London: Thomas Nelson and Sons. 1947.

*Curare: Its History, Nature, and Clinical Use.* By A. R. McIntyre, Ph.D., M.D. (Pp. 240. 27s. 6d.) Chicago: The University of Chicago Press. London: Cambridge University Press. 1947.

The author discusses botanical details, the chemistry of curare, its physiological effects, and its clinical uses.

*Obstetrics and Gynaecology.* By C. Scott Russell, M.A., M.B., F.R.C.S.Ed., M.R.C.O.G. (Pp. 214. 12s. 6d.) London: Geoffrey Cumberlege, Oxford University Press. 1947.

A short revision book intended particularly for returning ex-Service men.

*O'Meara's Medical Guide for India and the Tropics.* By H. W. Williamson, O.B.E., M.D., M.R.C.P., F.R.C.S.Ed. 5th ed. (Pp. 928. 30s., postage 1s. extra.) London: Butterworth and Co. 1947.

An alphabetically arranged guide to medical practice.

*Les Varices.* By I. Florian. (Pp. 137. 6 Swiss francs.) Bucharest. Les Editions d'Etat. 1947.

A monograph on varicose veins, including an account of their treatment.

*Differentialdiagnose der Lungenvöntgenbilder.* By Rudolf Zeeleder. 2nd ed. (Pp. 296. 28 Swiss francs.) Berne: Hans Huber. 1947.

The use of skigrams in the diagnosis of lung conditions; profusely illustrated.

*The Personality of the Preschool Child.* By Werner Wölff, Ph.D. (Pp. 341. 25s.) London: William Heinemann. 1947.

An account of the mentality of children aged from 3 to 5.

*Arthur de Bretagne.* By Claude Bernard. 2nd ed. (Pp. 156. No price.) Paris: J.-B. Baillière and Sons. 1947.

A drama by the famous French physiologist, written in his youth.

*Le Ferite Osteo-Articolari d'Arma da Fuoco.* By Stefano Morando. (Pp. 172. 900 lire.) Turin: Edizioni Minervina Medica S.A. 1947.

An account of gun-shot wounds of bones and joints and their treatment.

*Bassini's Operation Modified.* By Major V. P. Gupta, M.S. (Lucknow), F.R.C.S. (Pp. 36. No price.) Bombay: The Popular Book Depot. 1947.

An account of the author's modification of Bassini's operation for inguinal hernia.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 22 1947

THE INFLUENCE OF SHERRINGTON ON  
CLINICAL NEUROLOGY

Sir Charles Sherrington, O.M., will be 90 years of age on Nov. 27. To celebrate this notable event and to honour a great man we publish in the opening pages of this issue three articles on his life and work. It was in 1904 that Sherrington gave his Silliman Lectures, published subsequently in 1906 under the title of *The Integrative Action of the Nervous System*, at Yale University; so it is fitting that the appraisal of his profound contributions to neurophysiology is made in our opening pages by the present Professor of Physiology at Yale, Dr. John F. Fulton. As Dr. Fulton observes, *The Integrative Action of the Nervous System*, like Harvey's *De Motu Cordis*, marked a turning-point in the history of physiological thought, and in this the author's ninetieth year the Physiological Society prompted the issue of a new edition, brought out by the Cambridge University Press in time for the XVIIth International Congress of Physiology at Oxford in July of this year, the Yale University Press having generously transferred their ownership of copyright to the Physiological Society. The value of the new edition is enhanced by a 12-page foreword in which Sherrington once more illustrates his high qualities as humanist and philosopher. The decorticated animal, "a Cartesian puppet," is a mindless animal that "reacts with the fatality of a multiple penny-in-the-slot machine to certain stimuli, all of them, as in the case of the penny-in-the-slot machine, physical, and not psychical." Integration, Sherrington observes, has been traced at work in two great systems of the organism. The physico-chemical produced a unified machine. "The psychical creates from psychical data a percipient, thinking, and endeavouring mental individual." And he ends his 1947 foreword thus: "That our being should consist of two fundamental elements offers I suppose no greater inherent improbability than that it should rest on one only."

Sherrington the philosopher is considered elsewhere in this issue by Prof. A. D. Ritchie. Here we may inquire more particularly into the impact of his work upon the development of clinical neurology, an impact perhaps seen most clearly in the writings of Dr. F. M. R. Walshe, whose Victor Horsley lecture of 1946 appears abridged in the middle pages of this *Journal*. Perhaps the simplest way in which to assess the influence of Sherrington's work upon clinical neurology would be to turn to the volumes of *Brain*, or to those of any other representative neurological journal abroad, during the first decade of the present century, and then to pass on to the volumes of the same journals in the second and subsequent decades. The

contrast in outlook revealed by the later volumes is as striking now as it was while the change was unfolding before those who from about 1910 onwards were taking their first steps in clinical neurology. They had the great good fortune to begin their work under the inspiration of *The Integrative Action*, because, viewed in the light of the sequence of precise observation and of the principles so clearly evolved from them by Sherrington, the numerous reflex and motor disorders seen in affections of the nervous system in man began to gain a meaning and an orientation that they before had lacked. Disorders of movement and certain reflex reactions of limbs in cases of nervous disease were seen in the light of Sherrington's synoptic exposition. The old familiar signs one after another began to assume a physiological meaning, and thus progressively revealed the fundamental plan of the organization of movement and of posture in man, a plan which linked him with the humbler vertebrates, the monkey, the dog, the cat, in regard to their motor taxis.

It was not that clinical observation became more detailed or accurate, for indeed nothing could have exceeded in minute precision and descriptive clarity the accounts of disorders of movement and of reflex reaction in hemiplegia and paraplegia so abundantly given by the French school of neurology in the early years of this century. The pages of the *Revue Neurologique* of that time bear witness to the clinical acumen and scrupulously accurate observation that characterized the clinical neurology of the day, and even of still earlier days. Reading modern neurological literature, indeed, one may sometimes feel that our standards in this regard would be the better, perhaps, did we refresh ourselves from time to time by the study of these earlier models. What had changed after 1910-15 was not clinical skill or power of accurate description; it was the point of view. Once again, as before in Jackson's day, clinical neurology had received a fresh inspiration from physiology, and had been ready to accept it.

For too long, perhaps, the "physical sign" had been sought and cherished for its practical usefulness in locating the lesion and in pathological diagnosis. The point of view was empirical, and the link between clinical and physiological thought frail and not always evident. The literature of the early nineteenth century abounded in an ever-increasing number of eponymous signs, which, while they provided convenient symbols for the ends of description and of empirical classification, were regarded primarily as diagnostic weapons. When neurologists sought to relate them to normal modes of function the line of approach was loosely phylogenetic—for example, the writhing movements of the athetotic child were likened to the antics of our hypothetical arboreal ancestors. On such a soil false analogies grew readily, but in general the physical sign was a phenomenon pragmatically regarded and esteemed. It is but fair to say, however, that in this country the conscious intent to interpret signs in terms of disordered function had never ceased since Jackson's day, and the publication of *The Integrative Action* did not so much change the direction of neurological thought as give the physiological outlook a tremendous impact on the British school of clinical neurology, a stimulus which later spread in widening circles to every centre of neurological study

in the world. That this stimulus worked sooner and more powerfully here was perhaps our good fortune rather than our virtue, for we were nearer to the source of inspiration and had not—like neurologists abroad—to wait for translations, or to grapple as foreigners with Sherrington's occasionally formidable English, at times reminiscent of Doughty's in *Arabia Deserta*.

From 1914 onwards the pages of *Brain* have shown a series of important papers analysing clinically observed phenomena in terms of Sherrington's observations and interpreting them in terms of physiological principles as these were expounded in his writings. Such papers steadily increased in number until it could be said that the Sherringtonian influence had pervaded neurological thought. A fresh accession, deriving at one remove from the physiology of decerebrate rigidity and of muscle tone, came from the work of Magnus and his school, a true and direct offshoot from Sherrington's work. And what is true of the succeeding volumes of *Brain* is true of all neurological journals, and to-day it would be difficult to overestimate this influence or to find any field of neurological advance in which it is not somewhere evident. The gain to neurological thought and knowledge has been inestimable: they have become progressively less empirical. Scientific method and thought have enriched and given order to the abundance of facts of observation, detailed and precise, which are the treasury of clinical neurology. Clinical observation has come itself to enrich and supplement the body of experimentally derived neurophysiological knowledge. After all, the nervous system of man is the finest of its kind, the most complex and the most highly endowed with capacities for further development, and much of the study of that system, in health and in sickness, can come only from clinical observation. Thus the relation of experimental neurophysiologist with clinical neurologist has been one of a natural partnership, of give and take, and for this admirable consummation we owe more to the influence of Sherrington's thought and work than to any other source or combination of sources.

This has been Sherrington's gift to clinical medicine, a field of knowledge and a discipline which have always attracted his deep and sympathetic interest; an interest which has embraced not only the work but also, and with generous a mind, the individual worker. This kindest and most modest of great men "belongs," as Professor Graham Brown so well says, "to the world, and not to himself," and so, we hope, will accept the small tribute made to him in this week's *Journal*.

## THE CRIMINAL JUSTICE BILL

Reform in the law of criminal justice is long overdue. It is required not so much to raise the practice of the courts as to bring the law itself up to the level of existing practice. The new Criminal Justice Bill has been anticipated in recent years by the anxious consideration which the courts have shown in awarding punishment, particularly to the young offender. They have done their best to keep him out of prison, and have called in probation officers, doctors, Army authorities, and others in the search for a less dismal alternative. The Bill is an effort to enable the letter of

administration to catch up with its spirit. A similar Bill was introduced by Lord Templewood, then Sir Samuel Hoare, when he was Home Secretary in 1938. It was given a second reading without a division but had to be dropped on the outbreak of war. The new Bill repeats the principal proposals made at that time. It seeks to make the punishment fit not the crime but the criminal.

The power of courts to impose sentences of corporal punishment is to disappear. The Departmental Committee<sup>1</sup> which considered this subject in 1937 declared that corporal punishment as a court penalty should be entirely withdrawn. More recently the Joint Committee of the British Medical Association and the Magistrates' Association made a recommendation to the same effect. The Bill is silent on the question of capital punishment, but this will be a matter for free debate. "Penal servitude" with its ticket-of-leave system and "hard labour" with its suggestion of cranks and treadmill are to be abolished. A more debatable change is the abolition of statutory prison divisions. It might have been better to leave the classification of prisoners to be decided by the court rather than by the prison governor. The Bill gives more facilities to courts which desire a medical report. It has been difficult for a court of summary jurisdiction to obtain a report unless the offender was remanded to prison; now it will be possible to remand him on bail on condition that he submits himself to medical examination. It is not stipulated that the examiner must be a psychiatrist or that, if he has to do with a juvenile, he must have a knowledge of child psychology; the phrase used is "a duly qualified medical practitioner"; but apparently a particular practitioner may be specified by the court. If an offender is certifiable as insane a court of summary jurisdiction will be given the same power to make a reception order as a magistrate has already in the case of a person of unsound mind not charged with any offence.

It is in the amendment and consolidation of the law relating to probation that the Bill is most admirable. The system of probation has now stood the test of sixty years' experience. The character of the delinquent has been guided, his social background improved, employment found for him, and any mental deviation discovered. Power is now to be given to the court when it appears from medical evidence that the offender may be susceptible to treatment for his mental condition to require him to submit to such treatment for a period not exceeding twelve months. It might have been better to make the case subject to review at the end of twelve months, and to extend the period if thought desirable. The form of treatment is apparently left to the judgment of the practitioner; it may be residential or non-residential. Borstal is retained in the Bill, though the upper age limit is reduced from 23 to 21. Possibly Borstal, which has not quite come up to expectations, may give place ultimately to something like the new detention centres to which courts will be able to send under-age offenders. Even the word "prison" may one day follow "workhouse" and "asylum" into oblivion. There is something in a name, and here a change of name indicates a new outlook. Incidentally, the term "criminal lunatic," which escaped the fate of other obsolete terms when the

<sup>1</sup> Cmd. Paper 5684. 2s. 6d. net; also *British Medical Journal*, 1938, 1, 680

Mental Treatment Act, 1930, came in, will disappear under this Bill. Henceforth there will be no more "criminal lunatic asylums"; they will be "Broadmoor institutions" under the Board of Control, and the former "criminal lunatic" will be a "Broadmoor patient."

It is worth while trying to place in perspective the class of cases with which the courts have to deal, the predominant age groups of the offenders, and the principal crimes with which they are charged. Those whose business it is to attend assizes or quarter sessions are aware that a large proportion of the prisoners—at the present time, for understandable reasons, a very large proportion—are young men between the ages of 18 and 25. The calendar for the current session at the Central Criminal Court may be said to represent major crime in the county of London for one month, and to give a fairly typical picture of the country as a whole. It excludes, of course, juvenile court cases and cases dealt with summarily. Of the 177 prisoners 65 had not reached their twenty-sixth year, and just upon 100 were under 30. In about half these cases the offences charged were stealing in one form or another. There were also 13 cases of forgery, which is another form of stealing, and a rather smaller number in which the charge was that of obtaining money by false pretences or by fraudulent conversion. Only in 9 cases was the theft accompanied by threats or violence. In 14 other cases the offence was that of "causing grievous bodily harm"; in two it was manslaughter, and in one attempted murder. Sex offences were comparatively rare. Among these hundred young men, one was charged with indecent assault, one with a homosexual offence with an older man, and two with rape. Older prisoners, those over 30, include a few, the despair of judges and recorders, who have more or less a lifetime of convictions behind them, but also others who at a mature age are guilty of a first and sometimes apparently inexplicable lapse. But it is the younger men—and these, too, often come up with a long list of convictions—who are mainly responsible for the lengthening of the calendars, the prolongation of sessions to two or three times their normal duration, and the talk of increased post-war crime. Most of them were at school, or on the point of leaving school, when war was declared, and they have passed their later adolescence in a violent and unseemly world. Very few of them are in any respect mentally deficient; mostly they have a sharp intelligence. A committee of the B.M.A. declared<sup>2</sup> fifteen years ago that the term "mental defective" could not be applied to the great majority of such persons. Nor are they psychological cases in any special sense.

In a certain number of delinquents psychiatric advice—and in a smaller number psychiatric treatment—may be of value, but such cases are a small minority. Some years ago the Director of the Institute for the Scientific Treatment of Delinquency suggested that 10% of all adult offenders might benefit from psychiatric treatment.<sup>3</sup>

The problem in fact is sociological rather than medical. It is the problem of inducing some sense of social obligation in people whose impulses seem to be entirely selfish. For the solution of this problem, though religious, educa-

tional, and economic influences may all play a part, a wise and understanding administration of the law, aimed not only at the protection of society but at the reform of the criminal, is essential. The new Bill would have gladdened the hearts of John Howard, Jeremy Bentham, and Elizabeth Fry in its emphasis on prevention and reformation rather than retribution. We assume that it has the support, as its predecessor had, of the Prison Commissioners, whose office it may abolish, prison governors, visiting justices, and discharged prisoners' aid societies. It is something to sweep off the statute book in their entirety the various Whipping Acts, Hard Labour Acts, and Transportation Acts which have stood there as a confession of our failure since the early nineteenth century.

### TOXIC FACTOR IN BURNS

Controversy still continues on whether or not there is any important toxic factor involved in the illness which follows severe burning. Systematic biochemical studies<sup>1</sup> at Oxford failed to reveal any burn "toxin." A proteinase was found which might play some part in local blister formation, but the effects of this substance are apparently neutralized should it enter the blood stream. Later in the course of the illness losses of body weight, simulating a toxic state, were found to be associated with a negative nitrogen balance which could be corrected by increasing the intake of protein. This deficiency state is induced by an increased demand for tissue protein. These systemic reactions follow the immediate local effects of the burn with fluid loss into the burnt area and consequent haemoconcentration. Other systemic reactions may be associated, of course, with complicating infections.

Prinzmetal and his co-workers<sup>2</sup> have shown that when rats are burned and subsequently bled to death the amount of blood obtained from the animal is reduced compared with that collected when normal rats are bled. This reduction in volume is not necessarily accompanied by haemoconcentration and is therefore not due to diminution of the actual blood volume. Post-mortem examination of the animals shows renal congestion, compared with the pallor of the kidneys in otherwise normal animals bled to death. In a further paper<sup>3</sup> from the same laboratory the authors describe how the infusion of blood from a burned rat into the aorta of a normal rat proximal to the renal artery reproduces this picture of renal congestion and capillary atony in the kidney of the recipient. This evidence certainly seems to suggest the presence of some vasodilator substance in the blood of these particular burned rats.

Before assuming that a similar "toxin" may be produced in burnt human beings, it would be well to keep in mind some points about the nature of these experiments. Prinzmetal's rats were anaesthetized and immersed up to the neck in boiling water for 20 seconds. It is quite clear that this procedure would produce an intense hyperthermia in the animals, and the only comparable human burn would result from being ducked in boiling water. The local action of an extensive scald is unlikely to raise body temperature significantly. Before Prinzmetal's results can be applied to the pathology of human burns, we should hear more about control experiments on the effect of gross rises of body temperature.

## QUINONE AND HYDROQUINONE AS INDUSTRIAL HAZARDS

Hydroquinone is well known to amateur photographers as a developer. An ophthalmologist practising in Kingsport, Tennessee, where the Eastman Corporation have a factory which makes developers and other photographic products, saw a number of workmen who had brown stains on their conjunctivae. Investigation soon showed that there were as many as 50 cases of conjunctival staining or corneal opacity among men who had been in contact with either quinone vapour or hydroquinone dust. This sequence of events, which is classical in industrial toxicology, is described in two recent papers<sup>1,2</sup> on the noxious actions of quinone and hydroquinone.

The ocular signs of the condition were in the interpalpebral fissure. The conjunctiva showed minute spherical deposits of brown or black pigment and the cornea a superficial green-brown stain and—of more serious significance—greyish white opacities at varying depths. Biopsy of the conjunctiva from one case revealed the deposition of large brown globules in the basilar cells near the basement membrane, and of a more finely divided and more widely distributed intercellular pigment. After removal from exposure the pigmentation gradually disappeared, but the corneal opacities remained; apart from the ocular condition no haematological or other systemic effects could be detected. The degree of eye injury was correlated with the length of time the workmen had been employed in the dangerous environment, though there were marked differences in individual susceptibility. Staining of equivalent severity developed in one man in one year and in another in over 13 years. That the toxicity of a substance is largely a function of its physics and chemistry is underlined in this study. Both quinone and hydroquinone are unstable water-soluble reducing substances of formulae:

Quinone vaporizes without boiling at ordinary temperatures and pressures, and hydroquinone forms a finely divided dust. The stage is therefore set for atmospheric contamination and subsequent solution in body fluids and tissues.

When a poisonous vapour is involved in an industrial process, ideally, its escape should be prevented by completely enclosing the chemical system used in the process; failing this, the vapour should be removed at the point of production by exhaust ventilation, or diluted with large volumes of air to a previously determined safe concentration. A combination of these methods was applied by the Eastman Corporation. A colorimetric method was devised for estimating the concentration of quinone in the atmosphere, and the upper safe limit was fixed at 0.1 parts per million. The accepted criterion formerly had been the bearable level of ocular irritation, which was found to correspond to a concentration as high as 0.8 parts per million. The method employed depends upon collecting the vapour in isopropyl alcohol, developing the colour with phloroglucinol in potassium hydroxide, and then comparing the absorption spectra with previously prepared standards at a wave length of 520 m $\mu$  using an Evelyn colorimeter. With the same technique the atmosphere at various points

in the factory was sampled in order to check the efficacy of the newly instituted safety measures. For hydroquinone dust a level of 2–3 mg. per cubic metre was arbitrarily selected, pending further investigations directed towards determining the standard of absolute safety.

## TRUE HERMAPHRODITISM

True hermaphroditism is defined as the presence of both male and female gonads in the same individual. A review of the literature shows that it is a rare condition; only 2 cases proved microscopically have been reported. The sex of an individual was previously believed to be determined at the moment of union of ovum and sperm by the number of, or some intrinsic factor in, the chromosomes. Recent experiments suggest that other factors may play a decisive part in the determination of sex. Sisk and Cornwell state that abnormalities of genital development may result from endocrine imbalance in the mother or embryo. The normal growth of the genital tract depends on the continued development of the Wolffian elements and the simultaneous suppression of the Mullerian tract or vice versa. If the retrogression of the antagonistic elements in defective hermaphroditism results. Should the Mullerian and Wolffian elements be equally developed so that two ovaries, two Fallopian tubes, and a uterus coexist with two testes, epididymes, vasa, seminal vesicles, and a prostate the condition is classified as true hermaphroditism bilateralis. If the Mullerian tract is developed on one side and the Wolffian elements on the other, "hermaphroditism lateralis" is the term used. Two such cases have been reported recently, one by Stirling<sup>1</sup> and the other by de Moura and Basto.<sup>2</sup> A much commoner condition is that in which ovarian and testicular tissue are present in the same gonad (ovotestis) with an ovary or testis or neither on the opposite side; this is classified as "unilateralis." An ovotestis was found on one side in a case described by Davis and Scheffey,<sup>3</sup> and in another case reported by Engle, Yeaw, and Lattimer.<sup>4</sup>

Advice is usually sought in early childhood on account of some external genital deformity, such as hypospadias or cryptorchidism, or at puberty because of abnormal secondary sexual characteristics. When the sex of a child was in doubt it was customary to advise the parents to bring him up as a boy; the male is three times more prone to deformity of the genitalia than the female, and the disadvantages are less if a mistake has been made. Garcia states that only by an exploratory laparotomy can the true sex be determined, and some authorities would insist also on biopsy of the gonads.

The question of treatment is complicated by anatomical, endocrine, and psychological factors. The aim of surgery will be threefold. First, it is necessary to establish a functioning genital tract of the sex which has been decided upon in the light of the laparotomy; this may be impossible because of some essential defect in the development of the tract, and even if the organs appear normal sterility usually ensues. Secondly, it is essential to remove all antagonistic gonad tissue if unfortunate secondary sexual characteristics are to be avoided. Finally, the external genitalia may need reconstruction. The secondary sexual characteristics may have to be stimulated by appropriate hormone therapy before and after puberty, and the psychological aspect of the problem must receive adequate attention. All these points are well illustrated in the remarkable group of four cases recently described.

## BORAX AS AN INSECTICIDE

Before the advent of modern synthetic insecticides it was difficult to find any chemical substance toxic to insects which was not dangerous to vertebrates. Arsenicals and fluorine compounds present certain hazards when used against insects living in association with man or domestic animals. However, borax ( $\text{Na}_2\text{B}_4\text{O}_{10} \cdot 10\text{H}_2\text{O}$ ) and boric acid ( $\text{HBO}_3$ ) do combine moderate insecticidal activity with low toxicity to mammals. These compounds have been employed in ant baits and as dusts against cockroaches with some effect. But since ants and roaches are difficult to eradicate it would seem advisable to abandon borax for more highly insecticidal materials. Borax and boric acid have been applied successfully to the reduction or prevention of the breeding of fly maggots in manure.<sup>1</sup> Boric acid is more effective than borax, probably because it is more soluble and, weight for weight, contains more boron. The quantities required are  $2\frac{1}{2}$  to 3 lb. (1.1 to 1.35 kg.) of boric acid or 3 to 5 lb. (1.35 to 2.25 kg.) of borax per ton of manure. Farmers may view with caution, however, the possibility of building up a boron excess in the fields, especially with cereals which have low boron requirements.

Another use of boron against fly maggots has been reported recently from Australia.<sup>2</sup> There are a number of blowflies which, apart from the domestic annoyance they cause, are responsible for great losses by "striking" sheep—that is, causing a fatal myiasis. These blowflies can be controlled to a considerable extent by baited traps, but it has been found that the flies breed on the bait in the traps and many maggots escape to renew the natural population. It has been shown that borax added to the baits will prevent breeding in them without destroying their attractiveness.

## EMPIRE MEDICAL BUREAU

The Council of the B.M.A. has decided to establish an Empire Medical Advisory Bureau at its Headquarters in London, and we would draw attention to an advertisement in this week's issue inviting medical practitioners with administrative experience and organizing ability to apply for the post of Medical Director of the Bureau, the work of which will be under the general direction of a Committee of Management. It has long been felt both by medical men from the Dominions and Colonies and by those who do their best to help them when they come to this country that there should be one place and one person to whom they can come for advice on the numerous medical and personal matters the solution of which would go such a long way to helping them to make their visit pleasant and profitable. Most medical men from the Dominions and Colonies come to this country with a view to obtaining postgraduate instruction. Great Britain now has a wealth of medical talent and experience which is unequalled in Europe. The reputation of British medicine has probably never stood higher than it does to-day, and we may justly be proud of the fact that some of the fundamental contributions to medical science during recent years have been made by men working in this country. Postgraduate education is now in the process of being put on a more firm footing with the development of the British Postgraduate Medical Federation, under the direction of Sir Francis Fraser. Although the facilities for this work are not yet available, men working in the principal medical centres in Great Britain are always pleased to welcome and to help

the medical man and woman from the Commonwealth and Empire who come here to learn new things. Part of the work of the new Empire Advisory Bureau, therefore, will be to see that the Dominion visitor has all the information he wants about postgraduate study whether it is for the purpose of taking a higher qualification or for learning about new surgical and medical techniques.

In this country we perhaps tend to forget that the Commonwealth visitor arriving in England for the first time feels very much of a stranger, is faced with unfamiliar customs, and is naturally ignorant of those various details that can be so harassing to the stranger. An important part of the job of the Medical Director of the Bureau will be to see that the newcomer is put in touch with suitable lodgings and hotels, receives information about facilities for sport and travel, and is introduced to medical men in this country who are prepared to offer private hospitality. Through members of the Branches and Divisions of the B.M.A. it is hoped also to arrange that the man or woman doctor from the Commonwealth will be greeted as soon as he arrives, whether it is at an airfield or at one of the ports. Here indeed is a job well worth doing and one which will enable the bolder of it to play a more than useful part in tightening the bonds that already exist between the medical men of Great Britain and the Commonwealth and Empire.

## PURCHASE TAX ON DRUGS

The Chancellor of the Exchequer in his Budget speech on Nov. 12 proposed certain increases in the present rates of purchase tax. The tax on the doctor's traditional black bag will increase from the present  $33\frac{1}{4}\%$  to  $50\%$ . Most instruments will continue to be free from purchase tax, but the tax on the lamp in cystoscopes and ophthalmoscopes and similar instruments will be increased. More important, however, is the fact that a large number of drugs are likely to become subject to tax at  $33\frac{1}{4}\%$  of the wholesale price instead of  $16\frac{3}{4}\%$ . This increase will affect many of the alkaloids and barbiturates; thiouracil and digitoxin; quinine, mepacrine, and pamaquin; aspirin, phenacetin, and the bromides; cascara, liquid paraffin, and castor oil; and most of the extracts, liniments, tinctures, syrups, elixirs, and the like. Under the Purchase Tax (Exemptions) (No. 2) Order of 1945 penicillin and the sulphonamides, vaccines and sera, cocaine and morphine, and vitamins A, B, C, and D, except in ampoules for injection, are exempt from purchase tax, as are pethidine, procaine, and certain other preparations. The British Medical Association has already protested to the Ministry of Health against this increase in the cost to the patient of a wide range of prescriptions. Many of the drugs affected by the proposed increase in purchase tax are in constant use by the dispensing practitioner. A substantial rise in the cost of these medicines is bound to fall most heavily on the chronic sick. The Association has urged that the whole question should be reconsidered.

The Treasury is clearly interested in the revenue from the taxation of nationally advertised proprietary medicines. Penicillin and the sulphonamides, among other things, have been treated differently. They have not been subject to purchase tax and it has not been thought necessary to alter this exemption. Surely there is a case for widening what Mr. Dalton called the "free list" to include drugs which are just as essential to the treatment of the individual patient. It is illogical to apply a purchase tax to the treatment of toxic goitre or malaria while exempting from tax the treatment of pneumonia or gonorrhoea.

# PHYSIOLOGY OF THE CEREBRAL MOTOR CORTEX: THE CONTRIBUTION OF CLINICAL STUDY\*

BY

F. M. R. WALSHE, M.D., D.Sc., F.R.S., F.R.C.P.

*Physician to the National Hospital for Nervous Diseases,  
Queen Square*

ABRIDGED

[After a tribute to Sir Victor Horsley.]

The methods and the fruits of the experimental study of the motor cortex are known to us all, and the familiar diagrams in which the topographical localization of movements in this cortical region have been embodied by numerous observers look out on us from the pages of innumerable papers and textbooks. On the other hand, this is by no means true of the remarkable contributions of the clinical method to the physiology of the motor cortex. Even contemporary clinicians commonly show an imperfect appreciation of their nature and significance, as may be seen from the unquestioning acceptance they give to the punctate theory of the localization of movements in the cortex, despite the numerous ways in which this theory conflicts with the clinical study of disorders of movement: while for the contemporary physiologist all this clinical work is an imperfectly explored world of phenomena and thought.

The last third of the nineteenth century was a period of great intellectual excitement for those engaged in the study, clinical and experimental, of the nervous system. As we read the original papers of the time upon this subject, naive as is their phraseology in some respects, we can recapture some of that excitement, and can realize how the experimental confirmation of Jackson's hypothesis of a localization of somatic function in the cerebral cortex, by Hitzig in Germany and by Ferrier in this country, stirred the imagination. Thus it was that the philosophic genius of Jackson, and the pioneer work of Ferrier which was stimulated by it, together opened what I have always looked upon as the golden age of British neurology. At this fortunate time Horsley began his work, and came to take his due place in the direct line of those, clinicians and experimentalists, through whom have flowed the two main streams of our knowledge of the cerebral motor cortex.

## Experimental Contribution and Hypothesis

What has predominantly occupied the experimentalist during the seventy-five years of investigation of the motor cortex has been the progressively detailed charting and subdivision of the excitable region, and innumerable maps, from the simple ones of the pioneers to the beautifully detailed ones of Leyton and Sherrington, bear witness to the perseverance and accuracy with which these surveys have been carried out.

If the physiologist, absorbed in these studies, has concerned himself at all with the problem of the functional organization of the excitable motor cortex it is because his punctate electrical stimuli soon began to reveal to him a perplexing instability in the reactions of the cortex. The factors underlying this were later to be analysed by Graham Brown and Sherrington, but this analysis cannot be said to have had any deep influence upon the general conclusions formed by the following generation of experimental physiologists as to the plan underlying the representation of movements in the cortex. This plan is generally held to be that the motor cortex is a close-set mosaic of points in each of which is represented, or localized, a physiological unit of movement: "One spot, one movement" for the majority of physiologists, the whole making up a somatotopic projection of moving parts on the surface of the cortex.

There is an engaging simplicity about this conception that is in the true tradition of Newtonian physics, but it has progressively crumbled, almost unnoticed, until upon examination

it is found to have no solid foundation. Horsley was one of the first to cast doubts upon its validity when he pointed out that there was no ground for the current assumption that the fragment of movement evoked by a momentary threshold electrical stimulus of a cortical point was all that the point really represented, and that in any case the stimulus was a grossly unphysiological way of exciting a nervous centre.

Graham Brown and Sherrington's analysis of the so-called cortical instability or liability showed that the activity of a cortical point is in fact influenced in a number of definite ways by its past behaviour, and its future behaviour by its present. To the conception of primary facilitation they added that of secondary facilitation with its consequences of the deviation or reversal of the response of a cortical point. These phenomena became the basis of Leyton and Sherrington's exposition of motor cortical function. In them they saw indications of "rich mutual associations" of cortical points, associations by means of which the units of movement assumed to be represented in individual points were built up into the innumerable combinations and sequences that go to make the normal movements of the intact organism.

[The lecturer summed up the present position by saying that although the cortex is a labile organ, there has been added to the notion of a perpetual flux of representation, so that the idea of a representation is gone, and to call the cortex labile or unstable gives us nothing in its place. Yet the punctate theory still appears to command the formal assent of physiologists, a telling example of the survival of what was once a useful working hypothesis which had become an obstacle to the penetration of fresh and original thought to the problem of the motor cortex.]

It is a fair criticism of the experimental study of the motor cortex that it has stopped short of giving us a clear insight into the functional organization of that cortex, and that in some of its aspects current physiological opinion shows signs of regressing to a simplicity wholly inadequate to generalize the facts of observation. I venture to submit that this failure is not so much due to a lack of relevant facts as to one of conceptual thinking about them. We may discern at least three factors underlying this. First, successive generations have continued to interpret their findings on the basis of the original punctate localization theory, the permanent validity of which they have assumed. Secondly, they have departed from the concept of a representation of processes—that is, movements—in the cortex in favour of one of a representation of structures—that is, muscles; and thirdly, in coming to their conclusions they have left out of account, by a sort of unawareness, all the facts of observation that did not harmonize with the theory, thus giving an example of the insufficiently recognized truth that the relevance of evidence is always dictated by theory, a quality inherent in the observational order of experience.

[After this brief and somewhat critical review of a vast body of experimental work with its great merits and obvious limitations, the lecturer turned to his main theme, the clinical contribution, which this introduction brought into relief.]

## The Clinical Contribution and Hypothesis

That these studies have almost from the first taken a very different path from the one we have just traced we owe to two circumstances: the one inherent in the clinical method, the other fortuitous.

The limitation inherent in the clinical method is that Nature makes the experiment, and not the observer. She makes it for and when she likes, seldom as we should desire to have it, and still more seldom under the eyes of someone interested to assess its significance in terms of physiology. "Experiment," it has been said, "is nothing else than a method of cooking the facts for the sake of exemplifying the law"; but the clinical observer has to take Nature's facts in the raw, and to elicit Nature's law in these circumstances may be a high adventure of thought.

The second and fortuitous, though most happy, determination was that the pioneer in the field, Hughlings Jackson, characterized by at once a scrupulously accurate observer and a man of philosophic genius. He was quick to recognize that once the fact of a topographical representation of movements in a certain region was established, the further and more practical mapping of that region could be left to that experimental method which Ferrier had begun to show was so eminently suited to the task. He was thus free to turn to what was

\*The Victor Horsley Memorial Lecture delivered at the National Hospital, Queen Square, on Nov. 27, 1946, and here abridged. The complete lecture is published by E. and S. Livingstone, Ltd., Edinburgh: price 1s. 6d.

him the more congenial task of analysing the nature of this representation. To this end he adopted what he called his "double plan": namely, the parallel study of the consequences of destroying and of discharging lesions, that is, of analyses and of those convulsions beginning unilaterally that we now speak of as Jacksonian fits. In one of his papers Jackson says:

"I considered convulsive seizures and certain cases of paralysis which regard only to the localization of movements in the brain. What interested me most was, not so much the localization of movements in the cerebral hemisphere in the sense that, for example, the movements of the foot are localized here and those of the arm in another place, but the facts of the cases as they bore on a broad principle of localization."

Here, surely, is the authentic method of science, philosophically considered, with its observational and conceptual elements, and here, thus early, the clinical study of the motor cortex set its course for a different goal from that sought by the pioneer experimentalists. For myself, I know of no more fascinating episode in the history of clinical medicine in modern times than Jackson's intensive study of the convulsion beginning unilaterally, as he called it, and the masterly fashion in which he made it yield up so many of the secrets of the cortical organization of movements.

[The lecturer described as the classical example of the "discharging lesion" the Jacksonian fit, and of the "destroying lesion" hemiplegia in all its grades of severity.]

We have learned that, *ex hypothesi*, the motor cortex is a mosaic of discrete points in each of which a muscle or a unit of movement is represented, and, from what we have heard, all these points are to be thought of as equipollent. How remarkable it is, then, that the Jacksonian fit, with this vast and complex representational mosaic at its disposal as it were, could invariably choose to fire off in one or other of three critical foci: that for thumb and index movements; that for movements at the angle of the mouth; or that for movements of the hallux, and in that order of frequency. An inevitable result of this selective incidence of the discharging cortical focus, for which nothing in the literature of experimental physiological studies has prepared us, is that the Jacksonian fit begins in what has been called a leading part (a part having the greatest number of different movements at the greatest number of different times)—namely, hand, face, or foot. From these observations Jackson concluded that these three cortical foci—"physiological fulminates," as he called them—possessed the lowest threshold of excitability in the motor cortex. Again, in respect of each point of onset of the fit there are certain uniform sequences of spread. Of equal significance as a general characteristic of the fit is that it spreads in a uniform sequence. In respect of the discharging lesion itself, Jackson believed that though this might be restricted, it could yet lead to a widespread convulsion.

#### Paralyses of Movements

Tracing the general features of hemiplegia, the effect of the destroying lesion, we find that they include the maximal incidence of impairment or loss of movement in the same three leading parts we have already considered—hand, face, and foot, in that order. As hemiplegia increases in severity, or in the comparative study of a series of progressively more severe examples, we see the same compound order of involvement that we found to be characteristic of the Jacksonian fit: as paralysis spreads to include more movements it deepens in the movements first affected.

Now hemiplegia is usually the sequence to a destroying lesion of the motor pathway deep to the cortex, the way out from the cortex, but the study of limited destroying lesions of the cortex itself reveals that the general characters of the paralyses observed are the same in each case. Nevertheless there are certain significant features of destroying cortical lesions to be considered. As Jackson expressed it, the cortex is very tolerant of destroying lesions. If such a lesion be very restricted it may be symptomless, and when productive of paralyses these are apt to be minimal in range and severity and to be capable of a high degree of restoration. Nevertheless, this apparent restoration is not truly complete, for of all the possible movements of a given part some remain absent, but are largely compensated for by other and similar movements of the same

part. This so-called "tolerance" of destruction, the high degree of recovery after a destroying lesion, and the nature of the compensation achieved are all incompatible with the theory of an exclusive representation of movements in certain fixed points.

Summing up, then, we have primary involvement of leading parts in paralysis, compound order of paralysis of movements in the same sequence as that of convulsion in the Jacksonian fit: tolerance of the cortex to localized lesions, extensive recovery and partial compensation of lost movements by similar movements of the same part. Thus convulsion and hemiplegia are the positive and negative of one picture, and convulsion "the mobile counterpart of hemiplegia." The destroying lesion reveals yet another feature inherent in the organization of the motor cortex—namely, that it is movements and not muscles as such that are represented. "The cortex knows nothing of muscles, it knows only of movements," as the familiar aphorism of Jackson's has it, and it must at this date strike the clinician as remarkable that any should be found to dispute it.

In the matter of paralysis there is no evidence that a single muscle can be paralysed by a cortical lesion in man. It is doubtful whether in the experimental animal after a cortical ablation any conclusive finding on this matter is possible. On the positive side there is ample clinical evidence that paralyses from cortical lesions and in hemiplegia are paralyses of movements and not paralyses of muscles as such. One of the most familiar examples is provided by the behaviour of wrist extensors in many cases of residual hemiplegia: those in which the power of voluntary clenching of the fist is retained but that of voluntary extension of the wrist is lost. In the former movement the wrist extensors can be seen and felt to contract powerfully, while on the attempt to extend the wrist nothing happens and the muscles remain inactive. As synergists in the first movement they act, as prime movers in the second they are paralysed. Even more striking instances are recorded by Beavor (one of Horsley's collaborators) in the case of movements of the trunk in hemiplegia, showing that muscles paralysed for certain movements retain their full power in others.

[After adducing a philosophical argument against representation of structure—as opposed to process—in the cortex, showing that it can only be the *performance* of the muscle as a moving structure that can be represented:—]

Clinical observation has shown that the motor cortex pre-determines the combinations in which muscles shall act simultaneously, and also the sequence in time, the order of action, in which they enter into a voluntary movement. These are those cortical functions of co-ordination in space and co-ordination in time of which Jackson spoke and which Beavor so abundantly exemplified and recorded in his Croonian Lectures (1903).

#### Jackson's Theory of Representation

At an early stage Jackson found himself compelled to discard the punctate or "cortical muscle" theory of localization of movements as being incompatible with the facts of observation and inadequate to generalize them. What has been spoken of as the tolerance of the cortex to destroying lesions, and the remarkable degree and kind of recovery of movement seen after such lesions, could not occur with a cortex so organized. Similarly, the compound spread of convulsion from discharge of a restricted cortical focus is equally impossible on this basis. Jackson therefore concluded that representation of movements must be multiple in the sense that a given cortical focus must contain the anatomical and physiological substrata of more than a single movement, and that the representations of the movements of a given moving part are not abruptly demarcated and merely contiguous but extensively overlapping.

Implicit in this view, and in strong contrast to that of the experimental physiologists, is the notion that what the motor cortex represents, what is "localized" there, is not a vast collection of elementary units of movement, waiting to be assembled *ad hoc* into those complex combinations and sequences that we know normal voluntary movements to be, but a field in which all possible movements—all the movements the individual has ever learned—have their own separate representations in so far as they differ from other movements. There is, in fact, no conclusive evidence that any hypothetical "units" of movement are represented as such in the cortex.

The hypothesis of multiple and overlapping representations allows of an integration of all the phenomena of facilitation with the known facts, and we no longer have to suppose that what deviation and reversal of response really signify is that a given representation actually changes its location from place to place and moment to moment, and that cortical representation is in a perpetual flux.

[Only on the basis of Jackson's theory of representation was it possible to account for the clinically observed facts. But in the field of experimental physiology the facts pointed to the same conclusions.]

The notion of multiplicity of localizations of movements in a single cortical spot stands out clearly enough from a great number of experimental observations. Thus it has long been known that if the faradic stimulus to a cortical point be prolonged a sequence of primary, secondary, and tertiary movements, as they have been called, can be evoked, and these involve a spreading field of musculature.

[The lecturer quoted from Horsley's Linacre Lecture in which he had drawn attention explicitly to the fact that multiplicity of representations at a single focus had always been an inference that could be drawn from experimental observations; also the recent work of two American physiologists, Murphy and Gelhorn (1945), who, using supra-threshold condenser discharges as their cortical stimuli, had found multiplicity of representation throughout the motor cortex of three animal types—rabbit, cat, and monkey—and also extensive overlap of representation, transcending the boundaries of the three great somatotopic regions, those of the head, upper limb, and lower limb. This multiplicity of representation persists in an isolated cortical focus and is not due to spread of current over adjacent areas of cortex.]

This consummation must be profoundly moving to whomsoever has been bred in the tradition of the great neurologists of the turn of the century. At last a great adventure of thought has come safely to port, and in the words of a phrase from Pope's *Essay on Man*, the motor cortex has been shown to be "A mighty maze! but not without a plan." Just as seventy-five years ago the clinically ascertained fact of a localization of somatic function in the cerebral cortex obtained its brilliant confirmation at the hands of Ferrier, so now the hypothesis as to the nature of that localization, based upon clinical observation and formulated so long ago, finds an experimental verification in the laboratory at the hands of two American physiologists. Now this clinical hypothesis may be regarded as valid on its own merits, and not in need of any further verification.

### Conclusion

The material and the conditions out of which the clinical investigator has to forge ordered knowledge are a constant challenge to his capacity for conceptual thinking as well as to his powers of observation. This chapter I have put before you is the story of the response to challenge. This particular challenge, which faces the experimental no less than the clinical investigator, is the challenge to conceptual thinking, a challenge we see so brilliantly met in the work we have been considering, or in that of Sherrington in the realms of experimental physiology. Science, it has been said, is formed by the meeting of the two orders of experience, observational and conceptual, and the former can be interpreted only in terms of the latter.

How appropriate to our thought of Victor Horsley is the conception of challenge and response, for his full and eager life was a series of responses to challenge. His name and fame are part of the imperishable tradition of medicine.

Medical practitioners might like to draw the attention of paraplegic patients to a new quarterly journal entitled *The Cord*. The journal may be ordered from the Editor, Paraplegic Branch of the British Legion, Stoke Mandeville Hospital, Aylesbury, Bucks, a year's subscription costing only 2s. Though the journal is issued by the Paraplegic Branch of the British Legion it will cater also for the interests of those paraplegics who are not members of the Legion. It will provide information about appliances and medical treatment suitable for paraplegics, and how they may best be obtained. General problems of housing and employment will also be discussed. The present number contains an entertaining short story, and announces the offer of a two-guinea prize each quarter for the best short story submitted by a paraplegic reader.

## A SUGGESTED HOSPITAL UNIT

BY

H. J. McCURRICH, M.S., F.R.C.S., M.R.C.O.G.,  
Honorary Surgeon and Gynaecologist, Royal Sussex  
County Hospital

For some time it has been evident to me that the private pay block in a hospital is obsolete. In such a block the segregation is based on social and not on medical grounds and patients lose the advantages that the less affluent obtain from specialized nursing and equipment. While by no means I advocate of specialization to the extent that many consider advisable, whereby a "special centre" is necessary before a malady can be treated, yet I think there can be no doubt that a reasonable degree of specialization is an advantage. I am convinced that this applies as much to the nursing as it does to the medical profession, or even more so. I have on many occasions heard surgeons remark that their cases do better both in the public and private wards of special hospitals restricted to the type of work concerned than do similar cases in nursing homes or the private blocks of general hospitals.

Sisters and nurses tend to be interested in special aspects of their work. Thus in a general pay block a fractured femur may be nursed by a sister specially interested in diabetes, and the requisite special equipment is not available, or, if it is, the staff are not familiar with it. It is for these reasons that private blocks have been provided in special hospitals. Not only does this apply particularly to fractures and orthopaedic cases, but also applies to genito-urinary, chest, and abdominal surgery, neurosurgery, and gynaecology.

In my opinion, the ideal conditions are those in which the surgeon works as part of a self-contained team of agreed and co-operative colleagues, medical and nursing, in a self-contained unit having all the facilities required for the efficient execution of his work, both public and private. The unit should therefore have general and private wards; it should, in the case of a surgical unit, have operating theatres, and an x-ray room for pyelography, salpingography, encephalography, or the correction of fractures, depending on the type of work engaged in. It is hard to think of any major surgical division that does not for its finest technique, require the help of x rays. There should be facilities for out-patients, both public and private, and a small clinical laboratory. Under such conditions a good technique could be developed; no doubt each "firm" would plan its own special technique, and this might be the subject of friendly rivalry. In this manner the method could be judged by results. In a pay block it is difficult to get a special technique followed in detail, and the procedures are apt to be a blend of the ideas of several surgeons—so often the best features of each method fail to be incorporated in the blend, and one often feels that the exact technique of any competent surgeon (if one cannot get one's own) would be better than a hotchpotch of many.

I have been thinking of these things for many years, but have been stimulated to put my thoughts on paper by the inspiring article by J. C. Spence on the subject of children's hospitals (*Journal*, Jan. 25, p. 125). I submit, as an illustration of what I mean, a plan kindly drawn up for me by Mr. Owen Watson, A.R.I.B.A., and his staff. It does not profess to be perfect in detail, and as I have already put these experts to a great deal of trouble by alterations and revisions I have refrained from further alterations as the plan illustrates my theme. There is, however, one detail that strikes me as needing changing—the plaster room should adjoin and communicate with the x-ray room, and it might be an advantage for the laboratory to communicate with the theatre suite. The private wards would be better grouped in one group and should not face the back of another building. Obviously, if such a plan were to be drawn up in connexion with a proposed hospital the nature of the treatment to be carried out there and the available site, as well as the personal views of those who were to work in the unit would make considerable alteration necessary. I therefore feel that at this stage there is no need to ask for the plan to be redrawn to provide for comparatively trivial revisions.

### Accommodation

The following are the main provisions in carrying out the scheme.

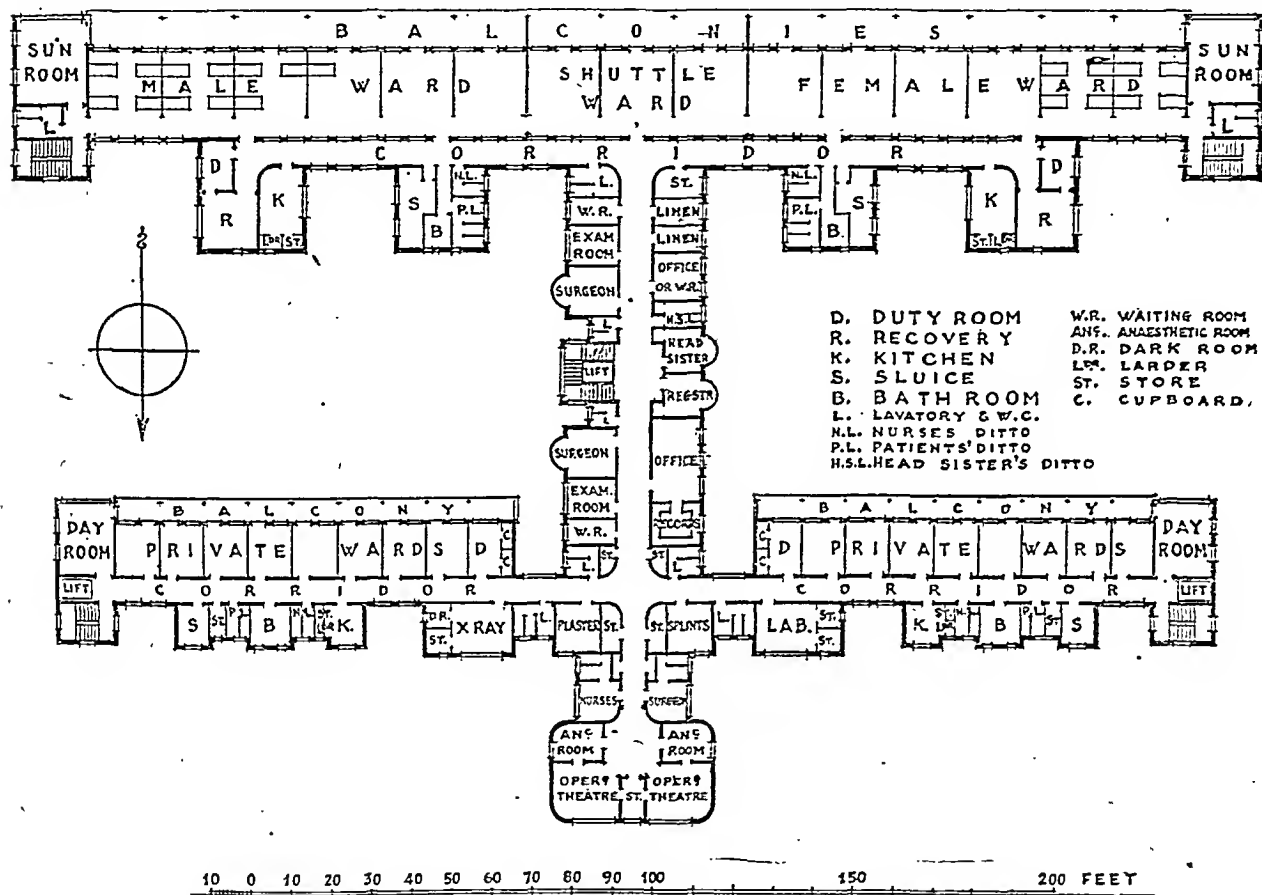

- General wards: male, female, and shuttle
- Private wards (single rooms)
- Theatre and anaesthetic rooms
- X-ray and developing room
- Plaster room if the unit deals with orthopaedic or fracture cases
- Splint store and store for Balkan beams, etc.
- Resuscitation ward
- Balconies adequate to accommodate a fair number of beds

There are, however, certain features to which I would draw attention.

**Shuttle Ward.**—To those not acquainted with this feature I would explain that a shuttle ward is one which forms an annexe to either the male or the female ward, it being situated between the two and with a door leading into either ward at each end.

ressing case. Attempts to reserve the single rooms for bad cases break down in practice, I find. If single rooms are provided, the private wards need not be separated for the sexes any more than are the rooms and floors in a hotel.

**Resuscitation Ward.**—The question of a resuscitation ward must be considered. It has advantages in the way of equipment and facilities, but there are objections. A much better relationship exists between nurse and patient when the nurse who has cared for him in *extremis* also nurses him through his convalescence: it is encouraging to the nurse and builds up a keen and happy spirit in the clinic. The beneficial influence of the gratitude of patients to the nursing staff is familiar to all who have worked in hospitals, and many patients make a point of returning when fully recovered in order to thank the sister of the ward and to bring her some flowers. On the other hand, it is an advantage to segregate a desperately ill patient, and to be able to come and go without disturbing the other patients; to

By opening the door into the male ward and closing that into the female ward the shuttle ward becomes an auxiliary male ward. It has no kitchen or sanitary accommodation, and is therefore cheap to build; it uses the kitchen and sanitary arrangements of the ward with which it communicates. This arrangement enables fluctuations in the number of each sex awaiting admission to be dealt with: If there was a big female waiting list, the shuttle ward could be used to reduce this by becoming a female ward, but if as a result a small hold-up of male cases occurred the shuttle ward could become a male ward for a week or two, and so on.

**Private Wards.**—Some advocate that two or three patients should share a room. This is satisfactory for trivial illnesses or for convalescents who are particularly sociable, but those who have shared a small ward with a patient taking two or three days to die of general peritonitis will need no further argument to convince them that, generally speaking, private single rooms are better. For myself, if I could not have a single room I would prefer to share with twenty rather than with one, as I should not be so likely to have such close contact with a dis-

use bright lights instead of groping to do an intravenous transfusion in the semi-obscurity of shaded lights, and to carry out all noise-producing procedures without disturbing other patients. The patient in such a ward is usually oblivious to the general turmoil.

It seems that both these advantages could be secured by having a recovery ward attached to each general ward. In the plan it is shown as having an observation window into the duty room. The ward staff, supplemented if necessary, could look after the very ill patient, would not lose contact, and would have the joy, if successful, of seeing the patient reach convalescence. On the other hand, if resuscitation failed, their disappointment and distress would be mitigated by the fact that they are not entirely engaged in this rather wearing occupation.

In the case of single private wards, there are few advantages in having a separate resuscitation ward.

### Personnel

This is not the place to enter into details, but certain principles should be established. To ensure unification there must be

unified control. There should, on the medical side, be one surgeon in charge of the whole unit. On the nursing side there should be a senior sister as unit sister, with theatre and ward sisters under her. She might combine her duties with a double appointment, as, for instance, unit sister and sister-in-charge of a ward or the theatre. On the other hand, she might take charge of wards or the theatre when the sister in direct charge of these is away, and she could advise and help the staff nurse, whose relative lack of experience should make her welcome such support.

The second principle is that of continuity. In many hospitals a complete change of residents occurs periodically, and the new resident has to spend a week or two finding his feet, with a consequent drop in efficiency. It is an advantage in any unit to have a senior and a junior house-surgeon. The junior becomes in time the senior and by that time is familiar with the work of the unit, and the newly appointed junior is supervised and helped by his senior, especially in the earlier weeks of his appointment. This principle should extend throughout the clinic. It does not follow that one man need progress all the way, held up for years by lack of vacancies, but new blood can be introduced at various levels without, however, a complete rupture of continuity. One sees in some municipal hospitals the ill effects of neglecting this principle. Whole-time surgeons are appointed without adequate deputies, and every time a fresh appointment is made a new man arrives, often with little or no introduction. He does not know any of the old patients, or the methods and traditions of the hospital. He inevitably finds a certain number of failures, for whom he feels no responsibility and little affection.

Continuity on the nursing side would be obtained by having several sisters and a unit sister.

#### Other Features

The importance of adequate clinical notes and records is universally recognized but as a rule most inadequately provided for. In this plan provision is made for a records office and accommodation provided for typists and clerks to help in keeping adequate and—what are too often lacking—legible clinical notes.

I do not wish to give the impression that I favour special hospitals: I am entirely opposed to the further creation of such hospitals. I feel that constant contact with those engaged in other branches of work is good for both doctors and nurses, and prevents isolation and a narrow outlook. In my opinion a general hospital should consist of a collection of units such as I have described above with a central administrative block containing, amongst other things, staff dining and common rooms where meeting one's colleagues in various branches would be automatic.

Space prevents further elaboration of this scheme, but enough has been written to present the idea as a subject for consideration, discussion, and development by those interested in the welfare of clinical medicine and surgery and the improvement and advance of our hospital service. It would be a great relief, to have one's work centralized, and not to waste one's strength and energy in transportation and in toiling up flights of stairs in inadequate nursing homes carrying bags of instruments and appliances, with the fear that the one instrument that may really be needed has been left at home; having to make do without such aids as suction or portable x-ray apparatus, and with no trolleys or lifts to carry the patient from the operating table to his bed. Surely what is best for the patient is best for us all: the finest work demands that all the most up-to-date facilities and aids should be available whenever required, and the practitioner's energies should be conserved and directed to the work for which he has prepared himself by years of study and experience and not be dissipated in trivial but fatiguing tasks.

At a meeting of the North of England Obstetrical and Gynaecological Society held recently Mr. F. J. Burke described a case of theca-celled tumour of the ovary. The patient was 74 years of age; the menopause had been 22 years previously. She had been a spinster until the age of 72. Apparently some rejuvenation had taken place, for sexual desire and marital intercourse were normal. She stressed that her marriage was the great event of her life. A theca-celled ovarian tumour weighing 20 lb. (9 kg.) was removed.

## Preparations and Appliances

### NON-CLOTTING NEEDLE FOR INTRAVENOUS INJECTIONS

Drs. G. P. FOX and J. H. TAYLOR, London Hospital, London, E.1, write: The increasing use of the intravenous route for anaesthesia brings the problem of maintaining the patency of an indwelling intravenous needle into special prominence. While on a visit to Stockholm in 1946, one of us (J. H. T.) was impressed by a needle devised by Dr. Torsten Gordh, of the department of anaesthesia at the Karolinska Hospital, and made by the surgical instrument firm of Stille.

This needle is the essence of simplicity and efficiency, and was fully described in *Anesthesiology* (1945, 6, 258). It consists of a shaft 3 cm. long of about 20 s.w.g., with a slightly thickened shoulder-piece 2.2 cm. in length, upon which is mounted at the end and at right angles to the shaft a small upward prolongation, surmounted by a detachable screw cap within which is a tightly fitting rubber diaphragm of 1.5 mm. thickness. The shoulder-piece is fitted with a thin-winged fin which lies snugly on the patient's skin and is maintained firmly by a strip of adhesive strapping. The overall length of the needle is 5 cm.

The patient is anaesthetized with a preliminary dose of thiopentone, and as soon as he is unconscious the needle is inserted into any convenient vein of the forearm or hand and maintained in position by the strip of adhesive strapping encircling the shoulder wing and the patient's arm. Further injections are made as required by piercing the rubber diaphragm with a very fine hypodermic needle mounted on a 10-ml. syringe.

The principle upon which clot formation is prevented is that blood cannot flow back into the needle once it is within the lumen of the vein since the distal end is closed by the rubber diaphragm. It is advisable before inserting the needle to inject a little of the anaesthetic fluid through it so as to expel any air which may have entered the needle through removal of the screw cap during sterilization.

The needle is easily sterilized by boiling, and the life of the rubber diaphragm varies with the extent of its use, but using only very sharp fine hypodermic needles a diaphragm will last from two to four months. No additional apparatus is required, and even an arm-board can be dispensed with if a suitable vein is found near the wrist and the hand is kept on the pillow by the side of the patient's head. We have used this needle now for over a year, and have never encountered clot formation within it, even when it has remained *in situ* for over four hours; neither have we seen any thrombosis higher up the vein, provided the needle is kept firmly within the lumen by means of the adhesive strapping. The uses to which this Torsten Gordh needle can be put are many. The anaesthetist will find it of service particularly when employing a thiopentone-nitrous-oxygen combination using intermittent, fractional doses of thiopentone and tubocurarine. In this case, since thiopentone and tubocurarine together form a dense precipitate, it is necessary to inject a small quantity of sterile saline after each injection in order to prevent the formation of such a precipitate.

Recently a minor modification of this needle has been made for us by Bleas Anaesthetic Equipment, Ltd., of 223/7, St. John Street, London, E.C.1. The shoulder wing has a thin rubber arm-band and buckle attached to it and this makes for easier fixation to the forearm without the use of adhesive plaster. In addition, the screw cap embodying the diaphragm is mounted at an angle of 45 degrees instead of at right angles, thus streamlining the needle, which is then less likely to project from the arm.

## LONDON MEDICAL EXHIBITION

The London Medical Exhibition, organized by the *British and Colonial Druggist*, returned to the hall of the Royal Horticultural Society, Westminster, last week with a varied display of products of interest to the medical profession. Quite half the 167 stands were devoted to the showing of chemical, pharmaceutical, and food products, the remaining exhibits being chiefly surgical and orthopaedic instruments, hospital and operating-theatre furniture, and special appliances for diagnosis and treatment. Unlike the exhibition of last year, when, after wartime dormancy, many new products were shown, the new introductions on this occasion were few and minor, but the exhibition excelled more than ever in the ingenious way in which the products were presented.

Many of the manufacturing chemists had illuminated models showing their products in action. This art of presentation was remarked particularly at the stands of Roche Products, Ltd., with its mural display of research workers and clinicians in the field of nutrition before and since the beginning of the vitamin era; Parke, Davis and Co., with its panorama of pharmaceutical research; and the decorative displays of Bayer Products, Ltd., the Crookes Laboratories, Allen and Hanburys, Ltd., and William R. Warner and Co., Ltd., with a relatively small range of products excellently shown. Imperial Chemical (Pharmaceuticals), Ltd., showed a more or less continuous programme of medical films illustrating anaesthetic techniques, and the British Oxygen Co., Ltd., had a big-scale exhibit of apparatus for the administration of anaesthetic gases. Of surgical instruments there appeared to be more than the former variety and abundance. One stall was entirely devoted to hospital equipment in stainless steel and another to surgical rubber. Hearing aids, electrical and non-electrical, were exhibited at several stands and rivalled ophthalmic equipment. Half a dozen bookstalls, three stands devoted to British spas—Bath, Buxton, and Harrogate—and such refreshing exhibits as those of Cadbury Bros., Ltd., and Bovril, Ltd., made attractive corners.

## Reports of Societies

### SNORING

In the Section of Laryngology of the Royal Society of Medicine on Nov. 7 Mr. IAN G. ROBIN read a short paper on "Snoring"—a complaint which was often a distressing physical and mental handicap. There was a remarkable lack of literature on the subject. Most physiology books devoted one line to it, and some journals of hygiene in America mentioned it in a breezy "lay" manner. Some useful information, however, was to be gained from recent work by anatomists and orthodontists.

Noisy respiration during sleep might be produced by various structures in the respiratory tract. He limited snoring to sounds made by vibrations in the soft palate and posterior faucial pillars during sleep. Whillis had shown that the vibrating part in a snore was the thin edge, or velum, of the posterior faucial pillars, and that if there was a reservoir of air filling the nasopharynx the velum could not vibrate. The vibrating parts were influenced by the relative position of the tongue and soft palate and by the texture of the velum. After a discussion of the position of these structures, the effect of the tone of the glosso-pharyngeal musculature, and other factors, Mr. Robin said that often it was the minor degrees of nasal obstruction which led to enough mouth-breathing to initiate snoring. These included slight deflection of the septum, collapsed alae nasi, or moderate mucosal congestion. Pathological changes in the pharynx might make the soft palate and faucial pillars more liable to be in a suitable state for snoring.

The majority of cases of snoring in children were cured by the removal of adenoids and tonsils. Exceptions were the cases of persistent mouth-breathing of functional origin and cases with infective or allergic rhino-sinusitis. It was rare for snoring to persist into adolescence. Even at puberty, when there was increased vascular congestion, there were not many snorers.

The child snorer did not progress into the adult type unless there was persistent nasal obstruction, nor did the adult snorer necessarily give a history of snoring as a child. The young adult who started snoring usually did so from some organic cause. The largest group of sufferers were elderly persons, and both men and women were affected. The majority had some functional derangement in the glosso-pharyngeal structures. Lack of tone seemed to be the fundamental cause.

### Treatment

Of irrational methods of treatment the chief was amputation of the uvula, which used to be a popular practice, rarely giving much relief, though it might modify the depth and pitch of the snore. Of rational methods the first was removal or prevention of nasal obstruction, thus allowing for cessation of mouth-breathing. In some instances decongestive nasal drops before retiring would allow a peaceful night. In others, various nasal operations might have to be performed. "Benadryl" was useful in some cases. The second method was to change the position of the head, thus preventing the tongue from falling back. Many persons snored only when on their backs, and sometimes a cotton-reel sewn into the back of the pyjamas was effective. The third method was to alter the position of the tongue and soft palate and perhaps also the jaws by breathing, swallowing, and phonetic exercises, or by orthodontic "splints." The exercises aimed at training the central nervous system to regain proper neuromuscular control. The "splints" altered the shape of the mouth, which might guard against the tongue and fauces falling into the critical position. In all these methods it was necessary to regain proper central control of the soft palate and break the habit of an inverted reflex.

A further method was to keep the mouth closed during sleep by wearing an "andresin" splint (which was well tolerated by most children, but less so by adults), or by the simple expedient of a strip of adhesive plaster across the corner of the mouth. After a short time this was well tolerated by many patients. An adequate nasal airway was, of course, essential. Jerome Strauss advocated the injection of sclerosing solution into the pillars, but no high percentage of cures had so far been claimed. Mr. Robin felt that surgeons might have prevented much future snoring by their removal of tonsils and adenoids, leaving the patient with nothing but a fixed fibrous band instead of a mobile soft palate and faucial pillars. His conclusion was that snoring was a symptom of unbalanced breathing caused by a combination of several physical conditions. Remedies must aim at curing all and not only one of them.

In a brief discussion which followed, the President of the Section (Mr. A. J. WRIGHT) said that for many years it had been his custom to teach students that snoring represented nasal breathing through an obstructed airway with the mouth open, but he was now satisfied that that was incorrect. Some remarks were made on snoring in animals. Mr. W. H. BRADBEER said that the dog was the only domestic animal that snored, and Mr. V. E. NEGUS said that this was because in the dog the epiglottis lay below the palate. The horse, cow, and cat would be incapable of snoring, as he believed they could not breathe through the mouth. He had always understood that in birds the sound was produced in the syrinx, and very loud sounds might be forthcoming. Mr. H. V. FORSTER inquired whether trained singers, whose muscles should be much better disciplined, were accustomed to snore, and also whether snoring occurred after operation for cleft palate. Mr. ROBIN was of the opinion that if the operation for cleft palate was attended by a good result the child should be capable of snoring but capable also, with efficient training, of not snoring.

### CARDIAC PAIN

A meeting of the Medical Society of London on Nov. 10, with Mr. W. E. TANNER, the President, in the chair, was devoted to a discussion on "Cardiac Pain."

Dr. WILLIAM EVANS said that after Heberden's classic description of angina pectoris there appeared to be nothing more to be said about cardiac pain; nevertheless he now detected a certain restlessness, an uneasy feeling that all was not well with

their knowledge of the subject. In the first place he wanted to discuss the term "angina pectoris" itself. Custom had associated "angina" with the heart, but the term was misused and abused, and dreaded by the patient. The loose terminology of "angina pectoris" should be left on one side and the more responsible term "cardiac pain" substituted. He also wished to see the term "cardiac ischaemia" substituted for "angina of effort."

The diagnosis of cardiac pain was founded on three cornerstones—the patient's narrative, the signs elicited on physical examination, and the electrocardiograph. The first two of these were insecure, and the electrocardiograph was the keystone. Pain over the heart was seldom a heart pain. A guide to the origin of the pain was often the way in which the patient described his symptoms. The patient with true cardiac pain would not over-emphasize or exaggerate; he dealt with his pain quietly and without recourse to rhetoric. He would describe it as tight, pressing, heavy; vice-like, dull, crushing, gnawing, boring, gripping. The patient with non-cardiac pain, on the other hand, would describe it as stabbing, shooting, sharp, pricking, knife-like, burning, niggling, stinging, piercing.

In cardiac infarction of the extensive kind diagnosis was simplified by the presence of obvious signs, which included shock, collapse, small pulse, distant heart sounds, and triple heart rhythm. In less serious attacks the blood pressure might sometimes give a clue, and another physical sign was cardiac enlargement. Triple heart rhythm would result from cardiac infarction either alone or when it had caused heart failure in hypertension. The auscultatory sound of triple heart rhythm in a patient with chest pain was without equal as a clinical test. Sometimes the triple heart rhythm would be due to the addition of a fourth heart sound coming in front of the first; this was met with when cardiac infarction had caused heart failure in hypertension. The other variety was due to the addition of a third heart sound following the second and was probably commoner.

#### Electrocardiography

Dr. Evans went on to ask and answer certain questions. Was the electrocardiogram of cardiac infarction or coronary thrombosis ever normal? He believed not. If this was true they must act on it in the future even more than in the past, and allow a normal electrocardiogram to exclude by itself the diagnosis of cardiac infarction, however much it might be upheld by the sudden impact of pain. Could the electrocardiogram provide early evidence of cardiac infarction? In his experience the changes were there from the start, not in their more obvious and stabilized form but none the less plain to see at the beginning of the attack. They need never wait in the false belief that the infarction must ripen before it produced its electrocardiographic effect.

The treatment of either cardiac infarction or ischaemia must be preceded by a clear-cut diagnosis. Enforced unwarranted invalidism was a cruel imposition at any age, most cruel when the autumn of life was clouded by unnecessary restrictions. For the doctor to miss a step here was to commit a wrong. Even when the diagnosis was withdrawn the real harm had been done, and the mental injury was lasting. The consequences of failure to recognize in a patient the marks of coronary disease were of equal moment. At these cross-roads, therefore, the doctor must read his signs clearly.

#### "Angina Pectoris"

Dr. JOHN PARKINSON said he was glad Dr. Evans had used the term "cardiac pain," but cardiologists would not use the term "angina pectoris" unless they were forced to do so. He objected to the term being thrown overboard. He did not believe that the average man to-day feared the term as much as he used to do. It was a rather serious matter to talk about removing a term which had been in existence since Heberden. The use of "ischæmia" for "angina of effort" also seemed to broaden the terminology until it became almost meaningless.

Dr. JENNER HOSKIN agreed that it would be a pity to lose the term "angina pectoris," though they should never use it before the patient, and its loose use on certificates was to be deprecated. "Effort pain" was probably a helpful way of

explaining it to the patient. He did not agree with Dr. Evans that the electrocardiogram was always abnormal in simple angina of effort. He had seen several cases with a typical history of angina of effort in which the electrocardiogram was perfectly normal.

Dr. A. HOPE GOSSE said that in diagnosing angina of effort he relied on the distribution of the pain rather than on the electrocardiogram. It was not always substernal pain, might be observed in the arm and forearm, sometimes in the form of a band around the wrist. It went up to the shoulder, the neck, the lower jaw and teeth.

Dr. R. W. COCKSHUT said that Dr. Hope Gosse had restored his faith in himself as a general practitioner, which had been imperilled by this reliance upon electrocardiography. Dr. G. SCHOTT showed radiographs of a number of cases in which the pain of angina of effort had been associated with other conditions. Dr. W. G. OAKLEY said that hypoglycaemia would produce cardiac pain in a patient who had coronary disease, though he could not recall any instance in which hypoglycaemia had produced cardiac pain in a patient without coronary disease. Dr. COWAN said that at a good many necropsies he had found quite definite infarction, but on going back into the history there was no evidence that the person had had any pain or had suffered in any way.

Dr. EVANS replied briefly to the discussion.

### MEDICAL HYDROLOGY

#### INTERNATIONAL CONGRESS

The annual meeting of the International Society of Medical Hydrology was held in Rheinfelden, Switzerland, on Sept. 10-14. Members representing nine countries were present. At a council meeting before the congress Dr. Barnes Burt (Bath) was elected chairman of the council. The vice-chairmen are Prof. Franstiel Lenocho (Prague), Dr. G. D. Kersley (Bath), and Prof. Walther (Geneva); the treasurer, Dr. F. Clayton (Leamington), and the secretary Dr. Donald Wilson (Bath).

At the first session Prof. STAUB gave an address on the effect of neuro-humoral reactions following irritation of the skin, and Prof. VERZAR, of Basle, described recent investigations of the climate at high altitudes. Prof. PANCONI, of Zurich, emphasized that spa treatment was an excellent form of therapy after the acute stage of poliomyelitis, but care had to be taken to avoid the over-use of healthy muscles at the expense of the paralysed ones. The temperature of the baths used should be between 96°-100° F. (35.6°-37.8° C.): lower temperatures would be too cold to relax any muscular spasm which might be present, higher temperatures would be too exhausting for the physiotherapists directing re-educational exercises.

Prof. CAMPBELL, of Pontresina, gave an account of his experiences in the treatment of asthma on the Engadine at an altitude of 5,500 ft. (1,650 m.). Of children who had asthma 50% were completely desensitized in six months, 75% in nine months and there was no recurrence when they returned to lower altitudes.

On the second day Dr. DONALD WILSON read a paper of balneotherapy in occlusive disorders and Raynaud's disease and Prof. LENOCH discussed the treatment of thrombophlebitis. In the afternoon, at Schinznach Bad, there was a discussion opened by Dr. NICHOLSON, on balneotherapy with sulphur water in non-rheumatic diseases.

The third day began with a discussion on spa treatment in rehabilitation after accidents and war injuries. Dr. McCLELLAN of Saratoga Springs, outlined the scheme which had been evolved by the American Army for the use of spas in the rehabilitation of the injured. Dr. BARNES BURT gave a short account of his experience with injuries during the war, and read a communication from the U.S.S.R. on methods of treatment of frostbite.

During the meeting members of the Society had much private hospitality offered to them, both by the Swiss members of the Society and by the members of the Swiss Society of Medical Hydrology and Climatology. This meeting coincided with the twenty-fifth anniversary of the International Society of Medical Hydrology.

## Correspondence

### Mental Health and World Citizenship

SIR.—Some of your readers will be familiar with this title, which is the general theme selected for the International Conference on Mental Hygiene due to assemble in London in August, 1948, as part of a rather larger Congress on Mental Health. This theme has been chosen deliberately in view of the present state of world affairs in the belief that many of us in medicine—not only in psychiatry—along with our colleagues the psychologists, sociologists, educationists, and others have an opportunity of learning to apply some of our understanding of individuals to the problems of group attitudes and international tensions. No doubt psychiatrists should be able to provide the central focus for much of the thinking that is necessary, but they certainly cannot do it alone.

This general theme of mental health and world citizenship has been broken down in a tentative way into various subjects for the different days of the Congress: "World Citizenship and Good Group Relations," "The Individual and Society," "Family Problems and Psychological Disturbances," "Industrial Relations," "Planning and Training for Mental Health." There are in London discussion groups or preparatory commissions composed of men and women from various allied professions, working each of them on one of these day's topics. In some 14 or 15 other countries there are already groups—in some cases, as in the United States, a great many—working on exactly the same topics. Their material as they produce it will be sent in to the central commissions in London, who hope to put it together and send out a monthly summary of all these various points of view to the other groups throughout the world.

This plan of preparatory action has been made because international conferences are often somewhat sterile, and we hope that in this case we shall be able to get a good deal of the work of the Congress accomplished before the meeting next August. At that meeting we actually want to exchange ideas and bring each other up to date in these matters. We hope that out of the work of these various preparatory commissions, which are of course on a national basis, and from the work of a residential International Group which we hope will meet before and after the Conference, we shall be able to clarify many of the points of agreement and disagreement. It should be possible to delineate many of the subjects which demand continuing research and inquiry in this medico-sociological field; and we hope also to be able to arrive at some points of agreement, however simple these may be, which could be of assistance to those two important functional organizations of the United Nations, the World Health Organization and Unesco, in the tasks to which their constitutions have committed them.

In this country there are a number of groups being planned, but there are not yet so many as there might be. As chairman of the organizing committee of the Congress I am writing now in the belief that many of your readers will feel that this provides them with an opportunity for getting together with colleagues from their own and other disciplines to try and study these topics and see what contribution can be made towards the solution of some of these major problems. Usually when one talks in any gathering about the general purposes of the Congress, about our intention to experiment in presenting group opinions rather than individual communications at the meetings, and about our desire to adventure out of our normal field of work into this wider region, one meets with general approval. It is, however, far from easy in these busy days to get men and women to settle down to serious discussion and to formulate their ideas on paper for the benefit of other people: but this is what we want. Certainly in every academic centre in this country there should be sufficient people with concern for the sanity and balance of society to provide separate discussion groups for each of the five topics; and, equally, there are many more isolated areas where perhaps the inter-professional nature of the group might be more limited, but yet there are people who could get together and produce much that would be of real value. Careful studies of much more limited subjects coming within the general field of interest of the main topics would also be welcomed. It is hoped that it may be possible to publish, fully or in summarized form, in the documents of the Congress such of them as are specially useful.

I hope that this letter may be taken as an invitation of a somewhat urgent kind to those who feel a concern about these matters to do something, and to get in touch with Prof. Flugel (the chairman of the programme committee) or with the programme secretary at the office of the International Congress on Mental Health, 19, Manchester Street, London W.1.—I am, etc.,

London, W.1.

J. R. REES.

### The Extent of Neurosis

SIR,—Is not Dr. H. Crichton-Miller's thesis (Oct. 25, p. 669) based on too narrow an interpretation of the facts? Effort directed against fear—if clearly envisaged—is but one means of giving significance and meaning to activity. I would suggest that this feeling of significance is the more fundamental factor in the apparent cause and effect he postulates.

Evidence in favour of such a view comes from a recent investigation of rate and standard of production in an electrical-instrument works. The story will be known to many of your readers. A group of workers were chosen and their co-operation obtained by explaining the objects of the inquiry. Various changes were then made, one by one, in their working conditions. Lighting was improved, seats were made more comfortable, music was provided, etc. With each change output improved. The dénouement came when conditions were finally put back to where they started—and still output improved! It was the opinion of those conducting the experiment that the feeling of purposeful co-operation in this group of workers was responsible for the increased work.

I suspect that such a feeling of significant purpose is encouraged in the U.S.S.R., and was inherent in the general "Weltanschauung" of that part of the Victorian era which produced "the finest work in quantity and quality." But to suggest that fear is the only or main source of such a feeling seems to me against the evidence, and an ethically undesirable philosophy.—I am, etc.,

Oxford.

C. W. M. WHITTY.

### Child-bearing and Tuberculosis

SIR,—Drs. C. J. Stewart and F. A. H. Simmonds are to be congratulated on their valuable paper on child-bearing and pulmonary tuberculosis (Nov. 8, p. 726). There can be little doubt that numerous pregnancies have been needlessly terminated. Diseases such as diabetes and syphilis are established or excluded by laboratory routine in antenatal clinics. A routine chest radiograph is perhaps even more essential than the routine W.R.

Modern tuberculosis therapy offers the greatest help to the pregnant woman who has early pulmonary disease, and there can be little doubt that a chest radiograph should form part of the early antenatal care of every woman.—I am, etc.,

Bournemouth.

D. J. AP SIMON.

SIR,—Drs. C. J. Stewart and F. A. H. Simmonds (Nov. 8, p. 726) are to be congratulated on their statistical research into the above question, and their conclusions will be gratefully received by tuberculosis workers throughout the country. Nevertheless it should not be forgotten that tuberculosis workers deal with individuals suffering from tuberculosis, with their families and contacts, and that from the point of view of the treatment of individual cases statistics may be very misleading. It is, for example, quite impossible to show by statistical methods that sanatorium treatment has any influence whatever on the course of pulmonary tuberculosis, yet those of us who have spent a lifetime in dealing with individuals suffering from this disease can recall the names of dozens or hundreds of our patients whose lives have been saved by prolonged sanatorium treatment and who would undoubtedly have succumbed without it. Similarly, while accepting the general conclusions of the Middlesex investigators that, statistically, pregnancy has little or no effect on the progress of pulmonary tuberculosis, we all can recall individual cases in which pregnancy led to disaster.

As a matter of clinical observation and experience the effect of pregnancy on an active case of pulmonary tuberculosis with cavitation and tuberculosis bacilli in the sputum is well recognized. Provided that the patient does not suffer from

hyperemesis gravidarum or other complication, the pulmonary condition usually improves during pregnancy, and this improvement is particularly marked in the later months. Whether this improvement is due to metabolic changes such as increased absorption of calcium, production of calciferol, etc., or can be attributed to some extent to compression of the lungs from below by the rise in the diaphragmatic level, is not known, but there is no doubt of its occurrence.

Then comes parturition and the puerperium, at the end of which in only too many cases one finds that all the progress made during pregnancy is lost and that an acute flare-up of the disease may occur. If we knew the cause of this sudden drop in the patient's resistance we could, perhaps, take appropriate measures. Is it due to obstetric shock, to loss of blood, or to the sudden re-expansion of the lungs with abdominal relaxation? Does it occur in women of primitive races whose delivery is easy? Does it occur after delivery by early caesarean section?

Collapse therapy by artificial pneumothorax when practicable is of course continued during pregnancy and pushed after parturition. But when artificial pneumothorax, although desirable, is impossible, should the induction of pneumoperitoneum, with or without phrenic crush, as soon as practicable after parturition be regarded as the method of election in such cases; or are there special risks attributable to the condition of the pelvic floor, etc., which render this treatment inadvisable? These are some of the questions which call for answers, and until the answers are forthcoming the temptation to terminate pregnancy in women suffering from active and acute pulmonary tuberculosis will remain.—I am, etc.,

Chichester.

P. HEFFERNAN.

### Heparin for Coronary Thrombosis

SIR,—Lest a massive dose of double strength be given as suggested in Dr. J. T. MacLachlan's letter (Nov. 1, p. 709), with what results I do not know, perhaps the massive dose recommended by Prof. Lambert Rogers in the *Practitioner*, October, 1947, p. 247—viz., 300 mg.—would be safer to give.—I am, etc.,

Worthing, Sussex.

R. H. WILSHAW.

SIR,—Dr. J. T. MacLachlan (Nov. 1, p. 709) advocates the use of heparin in cases of coronary thrombosis. On theoretical grounds it would seem that heparin is indicated in the treatment of this condition. On the other hand it would seem important to critically survey any extension of the use of an important therapeutic agent such as heparin before extending its use indiscriminately.

The interest in heparin has been stimulated recently by the classical work of Jorpes and other Swedish workers. It is of interest to note that these workers have confined themselves mainly to the use of heparin in the treatment or prevention of thrombosis arising in the femoral blood vessels following operations, and they have dealt with pulmonary embolism on the grounds that this condition arises as a consequence of undetected femoral-blood-vessel thrombosis. The femoral blood vessels have an elaborate collateral anastomosis, and heparin therapy will keep this collateral anastomosis open until such time as the original clot has become organized or organized. In Jorpes's work there is no mention of heparin for use in either coronary or cerebral thrombosis, and it would seem that the question of coronary and cerebral thrombosis was shelved because these workers felt that heparin would not prove of much value in these conditions.

So far as coronary thrombosis is concerned I would not use it myself because (1) once a thrombus is formed heparin has no further action and will not dissolve the clot; (2) a large number of cases will die from the shock and spasm attached to the attack of coronary occlusion, and heparin will be of no value, as these cases will die instantaneously; (3) the coronary arteries are end-arteries, and as such there is no collateral circulation to carry on after the attack of thrombosis; and I cannot see how heparin will prevent infarction or ischaemia of the heart muscle leading to ultimate impairment of cardiac output or death from rupture of the heart; (4) it would also seem that if the thrombosis is, as it is so often in coronary

thrombosis, secondary to some disease or degeneration of the blood vessel such as arteriosclerosis or atheroma, then a heparin has no curative action upon the condition which is causing the thrombosis we must not expect too much from heparin therapy. I am putting these points forward not in order to air my own views but in the hope that some cardiologist will clear up the doubts in my mind. It would be pity if a therapeutic agent such as heparin, which has been proved to be of value in certain specific conditions, should fall into disrepute because it has been used in conditions in which its use is unsuitable.—I am, etc.,

Southport, Lancs.

JOHN H. HANNAN.

SIR,—In his letter advocating heparin therapy for cases of coronary thrombosis Dr. John T. MacLachlan (Nov. 1, p. 709) suggests that it should be given after shock has been treated with morphine. He does not indicate clearly what delay there should be before using heparin. Unless someone can show any contraindications I would suggest that it be commenced as soon as possible after the attack. Pollard and I (*Quart. J. exp. Physiol.*, 1946, 33, 267) produced evidence that heparin, physiologically, does not appear to be a blood anticoagulant. It is stored in the tissues and only enters the blood as a result of trauma. The amounts released, as a result of trauma, are hardly enough to warrant its being called an anticoagulant. In fact, as normal clotting time lengthens, the action of heparin in physiological doses is to reduce it. We feel that heparin takes part in the "adaptation syndrome" described by Selye and almost certainly plays a defensive role in the body. The nature of its action is not yet understood, but its chemical character suggests that it will be an antibody to a number of substances which occur in the body, an example being histamine.

On the hypothesis that certain aspects of shock might be due to the action or overaction of histamine or similar substances, we tried heparin as follows. A female aged 72 years had been almost totally burned. When seen three hours after the accident she was very cyanosed. During 10 minutes 70 mg. of heparin was given. The cyanosis disappeared. A further 70 mg. was given by drip during the next 1½ hours. After another hour, during which no heparin was used, the patient developed acute pulmonary oedema. 75 mg. of heparin apparently completely relieved the condition. On two more occasions before the patient died (6 hours later) the pulmonary oedema returned and was similarly relieved by heparin. Heparin supplies were limited and this prevented more continuous administration.

We have seen several cases of migraine and a case of asthma quickly relieved by a skin prick, which would produce a natural outflow of heparin into the blood. It is likely, though not proved, that adrenaline is the chemical mediator by which heparin is discharged from the tissues into the blood. When its real action is understood, it is probable that heparin will find a useful place in therapy other than as an anticoagulant. Knowledge of this action will be gained more rapidly if clinicians are alert to its possibilities.—I am, etc.,

Osssett, Yorks.

S. B. STOKER.

### Health Regulations for Air Travel

SIR,—At the present time, with a continually increasing volume of air travel, any measures directed to the prevention—as far as possible—of the introduction of disease into this country by air-borne passengers is bound to be of interest. Dr. R. H. Barrett's article (Nov. 8, p. 741) gives a résumé of the regulations approved by the International Convention for Aerial Navigation, 1944. These regulations show clearly the amount of thought and planning (blessed word!) which has been devoted to the subject. Planning, unfortunately, is not infallible.

That there is a very real danger of the introduction of infectious disease by air which might be the starting-point of an epidemic cannot be denied. "We have reached the stage when we no longer think of countries overseas as being separated by distance, but by time. . . . That is to say that countries where all sorts of unfamiliar diseases flourish are nearer to this country in point of time than the length of their incubation periods" (Presidential Address, Surrey Branch B.M.A., July 2, 1947).

# no visas for vitamins . . .

Shortly before World War I the term "vitamine" made its debut in the medical vocabulary. Twelve years later the first concentrated vitamin preparation appeared in Britain. This was 'Ostelin' vitamin D, made then—and still made—by Glaxo.

Today the range of Glaxo vitamin preparations is available in almost every country. Indeed, few folk enjoy the same world-wide travel facilities as these Glaxo envoys.

## GLAXO LABORATORIES LTD.

GREENFORD, MIDDLESEX

Other factories and laboratories in England at Barnard Castle, Driffild, Stratford E.15 and Ulverston (under construction)  
In Argentina, Australia, India, Italy and New Zealand. Agents in almost every country in the world.

## CONCENTRATED LIVER EXTRACT

HEPASTAB FORTE is a highly concentrated extract of liver which has been prepared in our Nottingham laboratories as the result of research conducted by our own chemists in co-operation with clinicians in this country and abroad. It contains all the known anti-anæmic factors of liver, is highly refined, painless on injection and highly concentrated. Each 1 c.c. of Hepastab Forte is obtained from 100 gm. of liver and is therapeutically equivalent to 4,000-5,000 gm. of fresh liver by the mouth.

Ampoules of 1 c.c.: single ampoules, boxes of 3, 6 and 12 ampoules. Rubber-capped vials of 10 c.c.

Further information gladly sent on request to Medical Department  
BOOTS PURE DRUG COMPANY LIMITED  
NOTTINGHAM ENGLAND

\*Originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York

## Towards MORE NORMAL CONTROL

Successful control of diabetes cannot be claimed unless the blood sugar is kept within safe limits and the patient's activities are interfered with as little as possible. One injection of Globin Insulin (with Zinc) before breakfast is no great inconvenience and can control the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the Ideal—the normal control of blood sugar.

'WELLCOME' GLOBIN INSULIN (WITH ZINC)  
40 and 80 units per c.c., each strength in phials of 5 c.c.

**T. & H. SMITH, LTD.**

## GLYCODEINE

**GLYCODEINE** IS A VALUABLE SEDATIVE FOR THE RELIEF OF IRRITABLE COUGH, ESPECIALLY IN PHTHISIS, BRONCHITIS AND DYSPNOEA.

IT IS ALSO A USEFUL LINCTUS FOR THE TREATMENT OF ASTHMA AND LARYNGITIS.

**GLYCODEINE** IS EXEMPT FROM THE REGULATIONS OF THE DANGEROUS DRUGS ACT.

FORMULA. Codeine Phosp. 0.4, Liq. Tolu 13.5,  
Syr. Prunl Serot. 13.5, Glycerin ad 100  
Each dram contains  $\frac{1}{2}$  grain Codeine Phosphate.

It is supplied for dispensing  
in bottles of  $\frac{1}{2}$  lb. and  
1 lb. in bulk.

**BLANDFIELD CHEMICAL WORKS · EDINBURGH**

ALSO AT LONDON AND GLASGOW

## Hormone Therapy

'**PROGYNON**' in disorders occasioned by absolute or relative oestrogen deficiency.

'**PROLUTON**' in conditions where the underlying cause is progesterone deficiency.

Literature gladly sent on request.

**BRITISH SCHERING LIMITED**  
167-169 Great Portland Street · London · W.1

Compliance with the regulations in every particular may absolve the various airways corporations from charges of carelessness or neglect when supported by all the necessary certificates required by the regulations, but nobody could possibly claim that they are an absolute preventive. Only quarantine can do that. To insist on quarantine in the case of every passenger is manifestly unnecessary and impracticable. It was to avoid delay and inconvenience to travellers by sea that the system of sanitary surveillance was adopted by the Paris Convention, and on the whole it has worked well. It must not be forgotten that in travelling by sea infectious disease may reveal itself in the course of the voyage. Travel by air, by reason of its speed, is deprived of that natural safeguard to a very great extent.

To conform to the different conditions as far as possible, recourse is recommended to preventive inoculation by the Air Convention. As we know from past experience, inoculation is by no means an absolute preventive. It may, in fact, modify diseases to a sub-clinical and much less easily recognized type, in which the sufferer is just as much a possible source of infection. Moreover, non-carriers may be converted to carriers. This appears to have been foreseen to some extent by the adoption of a form of sanitary surveillance (*vide* "Health Regulations for Entry into the United Kingdom") and the "warning card" to be given to the patient's doctor. This measure is by no means foolproof. Pressure of business and shortness of sojourn are apt to cause the patient to "fight the disease" so that he may be able to get through his work in the time at his disposal. He may try to rationalize his symptoms as "another go of my old dysentery (or malaria)" until it lays him low and he has to call in a doctor, by which time he will probably have spread infection. His doctor may be unfamiliar with tropical diseases and inclined to accept the patient's own diagnosis until the illness takes a more serious turn.

I do not think too much value should be given to "personal declarations of health" for the same reason. It has not been unknown in the past for an individual to make a false statement for reasons of expediency to avoid being held up. Persons who make false statements or fail to comply with instructions may be a great menace, and if detected should be liable to heavy penalties. It would be a sound step if every airport which receives aircraft from overseas had provision for the temporary reception and rapid diagnosis in cases of illness in persons "deplaning." This should have facilities for blood and stool examinations on the spot, and the airport medical officer should be a man with considerable tropical experience. Such provision is a matter for each country to make the arrangements which it considers to be most efficient. It is not uncommon to find that persons who have lived in hot countries are carriers of typhoid or dysentery. I have seen a perfectly fit and healthy person who, in the course of a routine examination, was proved to be a cholera carrier. These are risks that have to be taken.

It would be too much to hope that we may continue to escape from air-borne infection indefinitely. Hence the importance of adequate provision for isolation and rapid diagnosis.

I wonder who invented the horrible words "disinsectization" and "disinsection"? Would not "disinfestation" have served the purpose?—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

### Appendicitis in the Young Child

SIR,—Dr. Howard Williams is to be congratulated on his paper (Nov. 8, p. 730) on the above subject. There is, however, a point in differential diagnosis which appears to me to need stressing and which I have not seen pointed out before. It is the inverted respiration (inspiration—pause—expiration—immediate inspiration) which is often found with the onset of peritoneal involvement. This is usually looked upon as a sign of intrathoracic disease and is especially misleading, as some 20% of cases of acute appendicitis in children are associated with or immediately follow upon an upper respiratory infection. The mechanism is the same whether the chest or the abdomen is involved; the breath is held in inspiration in the one case because of the pain of pleural involvement, in the other case because of the pain of peritoneal involvement, and the association of inverted respiration with the latter infection is particularly noticeable in childhood, where diaphragmatic respiration is naturally greater than costal respiration. Movements of the alae nasi are frequently present with the altered respiratory rhythm.

The correct diagnosis depends on the definite finding of focal abdominal tenderness or rigidity. This can be confirmed in cases of serious doubt by aspiration of the peritoneal cavity, a method I have never used but have seen employed in the U.S.A. with satisfactory results. The normal cell content is

about 2,300 per c.mm., and is mainly composed of mononuclears and lymphocytes. The pulse, respiration rate, temperature, and lymphocyte count are of little value, and x-ray films both of the chest and of the abdomen may be misleading.—I am, etc.,

Sheffield.

JUDSON T. CHESTERMAN.

### Anaesthesia for Head and Neck Surgery

SIR,—The flexible metal tube with mouthpiece described by Dr. J. G. Bourne (Oct. 25, p. 654) is an interesting piece of equipment. For some time an ordinary Hewitt's airway has been used in the same manner with good results. The fixed curve of this airway holds the tube so as to prevent deviation towards the oesophagus; it obviates the use of introducers, as does the curve given to the tube by storage in a circular tin. When large tubes are in use the airway required takes up a good deal of space, and there may be some difficulty in sliding it along the blade of the laryngoscope even if the Macintosh spatula is in use. Dr. Bourne's tube should be an advantage in these cases.

The use of "tubarine" for intubating cases of head and neck surgery is perhaps debatable, as a suitable dose of thiopentone given slowly, followed by nitrous oxide with a little trilethyl ether by passive ventilation, has been found to facilitate laryngoscopy and intubation. The same mixture is used for maintenance, and local analgesia of larynx and trachea is not required. It is felt that this sequence, using only a small amount of volatile anaesthetic, is less depressing than curarization; admittedly it takes more time.—I am, etc.,

Glasgow.

C. T. BARRY.

### Control and Treatment of Diphtheria

MONSIEUR.—Je viens de lire avec un vif intérêt votre "leading article" du *Journal* de March 22 (p. 384) ainsi que la suggestive étude de Dr. James Fanning (p. 371). Cette lecture me suggère les réflexions suivantes.

D'après Collins, 7% seulement des enfants non soumis à l'immunisation contractent la diphtérie au cours des 15 premières années de la vie. Pour que l'immunisation soit efficace, elle devrait donc protéger plus de 93% des enfants inoculés au toxoïde. Or, comme je l'ai montré dans un article—"Fréquence de la Diphtérie chez l'Enfant dans ses Rapports avec la Vaccination"—le pourcentage des Schick-négatives par l'immunisation active ne dépasse pas 85 à 90% (Ramon). La vaccination au toxoïde ne peut donc pas être efficace.

Vous dites qu'en 1947 en Angleterre 50 à 60% seulement des enfants sont inoculés. En 1941 cette proportion était forcément beaucoup plus faible et ne peut pas expliquer la baisse qui a commencé à ce moment. Tous les partisans de la vaccination antidiphtérique (Goldfley, Ramon, etc.) sont, en effet, d'accord pour dire que l'immunisation ne commence à produire ses effets que lorsque 40 à 50% au moins de la population infantile est immunisée. Si la diphtérie a beaucoup diminué en Angleterre depuis cinq à six ans, elle a diminué dans de bien plus grandes proportions dans des pays où l'on n'a pas vacciné. En Suède, par exemple, de 1919 à 1938 le nombre des cas a passé de 40,514 à 113 et celui des décès de 2,000 à 10.

Vous estimez que le renouvellement des injections de toxoïde rendrait l'immunisation plus efficace. L'expérience prouve qu'il n'en est rien (voir mon étude, "La Multiplication des Injections de Rappel Rendraient-elle Efficace la Vaccination Antidiphtérique?"). Veuillez agréer, mon cher Confrère, l'expression de mes sentiments les plus distingués.

Lyon, France.

ROBERT RENDU.

### A Method of Abdominal Palpation

SIR,—I was interested to read Dr. E. W. Price's article (Nov. -1, p. 703) describing his method of inducing relaxation of the abdominal wall, which seems ideally suited to ambulant patients or those already in the erect posture. In this country most patients are already supine at the time of examination, and time would be wasted in getting them up, just as with Dr. Price's ambulant African cases time would be wasted by getting them to lie down.

I have for some years used the following simple means of inducing relaxation in supine patients who, through nervousness

or anticipation of pain, cannot or will not relax, and which has not been, so far as I am aware, described in textbooks or taught in medical schools. The patient is asked to press his head hard back into the pillow. This simple action contracts the erector spinae, and in 19 cases out of 20 the abdominal muscles, which are antagonistic, promptly relax. Moreover, this draws the attention of the patient away from the part to be examined, and a gentle "patter" of conversation on the part of the doctor keeps it away. The principle of contracting a group of muscles in order to relax an antagonistic group is probably also the basis of Dr. Price's method.—I am, etc.,

London, S.E.5.

BERNARD J. FREEDMAN.

### "Unjustified" Use of *d*-Tubocurarine Chloride

SIR,—Dr. T. Cecil Gray (Nov. 8, p. 745) has drawn attention to what he describes as the "unjustified" use of *d*-tubocurarine chloride during anaesthesia for operations upon the head and neck. While agreeing with Dr. Gray in this respect I wonder whether he has not fallen into a similar fault in advocating the use of *d*-tubocurarine chloride in caesarean section—a procedure which he describes so ably in your issue of April 5 (p. 444).

To my mind the only possible reason for administering curare preparations to caesarean sections must be for its effect in relaxing the tone of the abdominal musculature, but surely this is quite unnecessary "since the muscles have been well stretched during pregnancy" (H. E. G. Boyle and C. L. Hewer, *J. Obstet. Gynaec. Brit. Emp.*, 1924, 31, 264). This relaxation can be observed quite easily when the obstetrician sews up the peritoneum, which latter can be lifted some inches above the level of the wound.

The increase in uterine tone observed in Dr. Gray's cases is almost certainly due to his use of thiopentone, "kemithal," or *light* cyclopropane, either alone or in combination, as can readily be demonstrated by omitting the administration of curare. Thiopentone and *light* levels of cyclopropane anaesthesia increase the contractility of the uterus, and since 1943, when we finally recognized this effect at King's College Hospital, the routine use of "pituitrin" has been abandoned after the employment of these anaesthetics. The first caesarean section ever to be performed under kemithal anaesthesia was at the same hospital, and the surgeon was Mr. John H. Peel; the date was Nov. 23, 1944, and in that and succeeding cases we rapidly came to recognize that this drug too had a similar tonic action on uterine muscle.

Propos of the above, I well remember the first time I administered a *light* cyclopropane anaesthetic for a caesarean section performed by the present P.R.C.O.G. Up to that time it had been his routine to inject pituitrin into the wall of the uterus just before making the uterine incision. On this occasion he persisted with the usual routine, but as his scalpel pierced the uterine wall the surgeon was hit smartly in the face by a geyser of liquor amnii and momentarily incommoded. Such an exhibition had never occurred while using gas-oxygen-ether and was the first of many instances (such as those attributed by Dr. Gray to the employment of *d*-tubocurarine chloride) which made us conclude that these three anaesthetics were uterine stimulants. Incidentally this property makes them useless for intrauterine manipulations or external version, although *deep* cyclopropane anaesthesia (which would never be used during caesarean section) does relax the uterus.—I am, etc.,

King's College Hospital.

A. H. GALLEY.

### Waiting for Operation

SIR,—A. B. is referred by his medical attendant to a particular consultant at hospital. A diagnosis of early carcinoma of the stomach is made and confirmed. The patient is advised to have an operation, to which he agrees, and he is put on the waiting-list for admission. Presumably the consultant has entered into a contract with the patient and his doctor to carry out the treatment. The patient is not admitted for six or even twelve months, and the growth becomes inoperable.

Is this the responsibility of the consultant or the committee of management of the hospital? Should the law decree that the onus is on the committee of management, is it not incumbent upon the committee to review the number of patients on

their waiting-list and to advertise or otherwise make known to all concerned what prospects they envisage of fulfilling the contracts to which they are party? Your decision on these questions is a matter of national importance.—I am, etc.,

London, W.1.

HAMILTON BAILEY.

\*\* Our Legal Correspondent writes: Any cause of action must be founded either on contract (agreement between the parties) or tort (civil wrong; in this case failure to use proper care). In each case the burden of proof is upon the patient. To succeed in an action for breach of contract he must show that an agreement, express or implied, existed to admit him to hospital or to operate on him, or both, while the growth was still operable. If he contracted for operation with the consultant, or for admission with the hospital, on this understanding and could prove it, he might have a chance of success. It is, however, hardly conceivable that either a consultant or a hospital would undertake such an obligation in these days of shortage of beds and would fail to tell the patient that he must wait his turn. Neither the consultant nor the hospital is required to do the impossible. If the patient seeks to found his action in tort, he must prove that the consultant or the hospital, or both, failed to use reasonable care. He might succeed if he could show that it would have been reasonable to warn him of probable delay and that he had not been warned, or that he had been wrongly deprived of his turn in the list, or if there was some other circumstance indicating negligence. Otherwise he would have no chance of success at law; and it may be said generally that in order to succeed he would have to prove a very exceptional state of facts. If he did succeed against the hospital, the committee would certainly be wise to make sure in future that they could not be taken to promise anything they could not perform regarding the interval of time between the acceptance of a patient and his admittance.—Ed., *B.M.J.*

### Morphine in a Patent Medicine

SIR,—In a medico-legal note (Sept. 27, p. 511) you referred to a case of death in a small child after drinking a quantity of a patent medicine sold for the purpose of relieving infantile disorders. You gave the quantity of morphine in the bottle but stated that it was not disclosed how this figure was ascertained. Actually, the Manchester City Analyst gave the quantity as a result of his analysis, and gave his evidence on oath at the inquest.—I am, etc.,

STANLEY HODGSON,  
Deputy Coroner, Manchester

Salford, 7.

SIR,—Dr. Paul B. Woolley (Nov. 8, p. 747), in quoting *The Chemist and Druggist Year Book* as his authority on dangerous drugs legislation, appears to have misinterpreted the paragraph he cites. Paragraph *e* (p. 339) (so far as it affects morphine) states that *any* solution or dilution of morphine in an inert substance is subject to the Dangerous Drugs Regulations; other preparations of morphine—i.e., preparations which are not solutions or dilutions in an inert substance—are subject to the Regulations if they contain not less than 0.2% of morphine.—I am, etc.,

London, W.C.2.

O. F. C. BROMFIELD.

### Vaginal Temperature

SIR,—Dr. John Hankinson (Oct. 11, p. 574) has drawn attention to the dangers which may accompany the taking of vaginal temperatures. A further similar case has within the last few days come under my care in which a woman had accidentally introduced a clinical thermometer into the bladder. She had been practising this procedure for some twelve months, not for the purpose of birth control, but in an endeavour to become pregnant. No trouble had previously been experienced until one morning she failed to find the thermometer and concluded it had been mislaid in the bedclothes. About midday, however, she experienced a sharp pain in the lower abdomen and some dysuria. It then became apparent where the thermometer was, and she sought medical advice.

An x-ray examination confirmed the presence of an intact thermometer in the pelvis, and the passage of a sound revealed the foreign body in the bladder.—After preliminary dilatation of

he urethra a pair of narrow-bladed forceps was passed into the bladder, the thermometer lightly gripped and, with the aid of a guiding finger in the vagina, easily withdrawn. A cystoscope was then introduced, and apart from some bruising of the rigone the bladder was seen to be intact. The occurrence of a second example serves further to emphasize the risks inherent in his undesirable procedure, and it seems that patients who follow his practice should be warned of its dangers.—I am, etc.,

Hove, Sussex.

W. R. FORRESTER-WOOD.

SIR,—The rectal (or vaginal) method of obtaining the basal temperature gives a more accurate record than the oral. To condemn the method because one woman has accidentally inserted the thermometer into the bladder is as unreasonable as it would be to disallow the practice of self-administration of an enema, when necessary, in case the nozzle was passed into the wrong passage. Dr. G. I. M. Swyer (Oct. 25, p. 672) would do well to read an article by Dr. Hales (*Medical Press and Circular*, May, 1946) in which he gives charts of a number of chronic diseases in which the condition would have been overlooked had reliance been placed on the oral recording. I know of an instance in which absence of the ordinary biphasic temperature record of the menstrual cycle drew attention to a tuberculous endometritis. The patient was wards for investigation, and it was observed that the temperature taken by the oral route failed to show the persistent slight rise shown by the rectal method.

The rectal route gives a more accurate degree of temperature. There are a few women whose records of the basal temperature in the pre- and post-ovulatory phase show only a slight difference in the fluctuations, the biphasic character of which could easily be missed if recorded by the less sensitive oral route.—I am, etc.,

London, W.1.

M. MOORE WHITE.

### Health Visitors

SIR,—The existing shortage may be attributed to a combination of causes: (a) greater demand on a reduced supply; (b) long course in training—as a nurse, midwife, and health visitor's certificate; (c) less call for change of area from stabilization of pay; (d) multiplicity of duties; (e) interference with training during the war. Two questions arise in one's mind to meet the existing demand: (1) Should a special interim short-term policy of a shorter course, or only a health-visitor's certificate course, be carried out? (2) Should only a long-term policy of existing methods of training prevail even at the expense of acute shortage for years—it may be five to ten years before normality reigns?

At the present time there is no doubt that considerable economy could be carried out in the use of health visitors and that in this respect either (or both) an assistant nurse or a voluntary worker could be utilized in the place of some of the duties now carried out by health visitors. Locally lady members of the maternity and child-welfare committee (both councillors and co-opted members) take turns of duty on a rota at my infant-welfare clinics. No trained nurse is required at an immunization clinic, at weighing of infants and toddlers, the recording of such, and the distribution of foodstuffs. With a doctor in attendance at infant-welfare clinics it should be possible with lectures on hygiene and baby welfare to release some trained nurses for hospitals, where the claim of the sick should hold priority for their services.

There are also some new fields now being attempted for utilization of the services of health visitors. I refer to immunization and blood withdrawal for Rh factor. A hypodermic injection is one thing, but an intramuscular injection of an antigen (capable sometimes of producing shock) and the introduction of a needle into a vein (not always at first shot) are quite different and definitely surgical procedures. In the latter of these unless great care is exercised in asepsis and method there can be a cause for toxæmia. Again this Rh factor concerns midwifery and the midwife at the antenatal clinic is more concerned with the result than the health visitor, and so surely the midwife should be trained to do this at the clinic. One has recently had judgments against a hospital in connexion

with a certain case, and it behoves us to defend our authority to the best of our judgment. On these thoughts I should like to have views of others, and perhaps we may get a lead from the Ministry on some of the problems raised.—I am, etc.,

Blyth, Northumberland.

A. G. NEWELL.

### Penile Carcinoma

SIR,—An experiment conducted on a national scale for two thousand years has proved that penile carcinoma is preventable by circumcision, and King Edward's question about tubercle, "If preventable, why not prevented?" is relevant to this form of cancer. As the writer of the annotation (Nov. 1, p. 699) observes, carcinoma of the penis is a rare disease. From a selfish point of view men need not trouble themselves about it unduly, but the interests of the other sex are involved. Correlated with the absolute freedom of Jewish men from this form of cancer is the relative freedom of Jewish women from carcinoma of the cervix. In New York, where three million of the eight million inhabitants are Jews, Dr. Maurice Lenz states that not 1% of the cases of cancer of the cervix occur in Jewish women. During a short visit to the Fiji Islands, where circumcised Fijians live alongside uncircumcised Indians, I obtained statistical evidence that cervical carcinoma is rare in the Fijian women but relatively common in the Indian women, no doubt from a transference to the vagina of the mixed bacterial flora that flourish beneath the prepuce.

As your annotation states, it is unlikely that the routine circumcision of male infants would commend itself to English opinion. But a simpler operation—slitting up the prepuce in the dorsal midline—would be equally effective, and in the first few days of life can be done without an anaesthetic. Only for a long phimotic prepuce is circumcision necessary.

The evidence indicates that routine preputiotomy for male infants would abolish penile cancer and ultimately reduce the incidence of carcinoma of the cervix in this country from about 4,000 cases per annum to 500 cases per annum. The principal obstacle to its adoption appears to be the erroneous belief that carcinoma of the cervix is the result of tearing of the cervix during parturition—an accident to which women of all races are equally liable.—I am, etc.,

London, W.1.

W. SAMPSON HANDLEY.

### Modern Treatment of Neurosyphilis

SIR,—I was most interested to read of the experiences of Drs. F. Graham Lescher and H. R. M. Richards in their article "The Modern Treatment of Neurosyphilis" (Oct. 11, p. 565). I note that their most successful results were obtained with combined penicillin and malarial therapy. The following two cases which I treated in conjunction with Sir Sidney Sewell early last year may therefore be of interest.

*Case 1.*—Mrs. B., a woman of 36, was found to have a positive Wassermann reaction when her husband developed neurosyphilis. She had no clinical symptoms or signs of disease, but the Wassermann and Kline reactions were positive +++ in both blood and cerebrospinal fluid, and the C.S.F. cell count was 40 lymphocytes. Prior to my seeing her she had had three courses of intravenous arsenic and intramuscular bismuth and one seven-day course of penicillin, 15,000 units three-hourly. Following the first course of penicillin the Wassermann reaction of her blood had been negative, but this had reverted to positive when I saw her, and the C.S.F. findings were as above.

She was put into hospital and given penicillin, 20,000 units three-hourly for ten days, and for the last seven days 5,000 units was given intrathecally twice daily. A month later the Wassermann reaction was negative in the blood but still positive in C.S.F. A further month later the blood Wassermann was positive +, and after another month positive ++.

She was then subjected to hyperthermia in the inductotherm to 105° F. (40.6° C.) for six hours, with two doses of penicillin, 50,000 units (the first at the commencement and the second three hours later) given intramuscularly. In all she was given twelve treatments at weekly intervals.

A month after cessation of treatment Wassermann reaction was negative in both blood and cerebrospinal fluid and has remained so with monthly blood and quarterly C.S.F. Wassermann tests since then—a period of eighteen months. Apart from one occasion (the fourth treatment) when she developed hyperpyrexia which responded to the usual measures, she tolerated the treatments well.

Case 2.—Mr. D., aged 42 years, was a tabetic. He originally had presented with gastric crises three years before. When I saw him for the first time he had been under continuous treatment with arsenicals, bismuth, mercury, and iodides for three years. He complained of intractable lightning pains and frequent severe gastric crises and was in danger of becoming a morphinomaniac. Wassermann reaction was positive +++ in blood and C.S.F.

He was treated by twelve inductotherm fevers combined with penicillin as in Case 1, and a month after cessation of treatment Wassermann reaction was negative in blood and C.S.F. Repeated tests for the past year have remained negative. Lightning pains disappeared after the fifth treatment and have not recurred, and there have been no further gastric crises. At the commencement of treatment both ankle jerks were absent; they are now present, though diminished as compared with a normal individual. He tolerated treatment well and was able to carry on his business in between treatments.

I have not had the opportunity of treating any further cases along these lines, but it seems to me that the inductotherm is to be preferred to malarial therapy. With skilled attendants the risks are slight and certainly no greater than those with malarial therapy. Where anaesthetic areas are present, especially over the heels or coccygeal region, burns are a very real risk, and the state of the pain fibres in these segments should be carefully tested before commencing treatment. The risk of hyperpyrexia can be minimized by skilled and experienced attendants. It is a very frightening complication, but prompt treatment should prevent fatalities. Using treatment at weekly intervals the patient's daily life is not unduly upset, and he can usually continue with his occupation, attending for treatment as an out-patient—a very important matter in these days of shortage of hospital beds.

Stratton St. Margaret, Wills.

SIDNEY A. SEWELL.

### Duodenal Ulcer and Priority Foods

SIR,—Dr. A. H. Morley's statement (Nov. 8, p. 745) that the symptoms of chronic duodenal ulcer are here to-day and gone to-morrow only to return another day, and that two pints of priority milk daily for these patients is squandermania, should not go unchallenged. The symptoms of chronic duodenal ulcer are chronic, recurring at regular intervals every day and every night throughout many years. Patients suffering from this disease have to learn and apply a strict and rigid regime of diet and conduct if they wish to avoid the symptoms of pain, vomiting, acid regurgitations, laryngeal spasms. Alkaline powders are often useless and even harmful. Small amounts of milk at frequent intervals is the best method of counteracting the hyperchlorhydria, and two pints a day is not over-generous. If any alternative to present certification were contemplated it should be to extend the period covered by the certificate to six or twelve months.—I am, etc.,

Harrold, Beds.

R. STUART.

### Milk for the Sick

SIR,—I feel that the following account of a recent and, presumably, continuing struggle with the food authorities may be of interest. The relentless undermining of the doctor-patient relationship is once more demonstrated and made very clear, and it is possible that ventilation of the story may be of help to someone in a similar predicament in the future.

Miss X. is a panel patient aged 54. She has a permanent gastrostomy necessitated by inoperable carcinoma of the oesophagus. Until a fortnight ago she required and obtained a special milk ration of 3½ pints (2 l.) per day. Two weeks ago this was without warning cut to 1½ pints (850 ml.) per day, but as a result of my intervention at the food office and at the cost of a wasted morning it was restored pending the consideration by the medical advisers of a "confidential" report from me.

Yesterday the ration was again cut without warning to my patient or myself to 2 pints (1 l.) daily, an allowance on which she will quickly starve. I visited the food office at once and was shown a letter which simply states that "Our advisers recommend that the patient be granted two pints of milk daily and a priority allowance of eggs for three months renewable . . . but they cannot recommend any supplies in excess of the allowance, and the request for five pints of milk must be

refused." This last request had not of course been made. Medical advisers had made no inquiries further to my original letter, nor of course had they or anyone else seen the patient. It would appear possible that these gentlemen are somewhat out of touch with the problems of management of gastrostomy in general practice.

At this stage, in an attempt to save my patient's life, I sought the help of the Association, and a very helpful secretary put me in touch with a charming gentleman at the Ministry of Food. To him, not a medical man, I was compelled by circumstances to disclose the patient's name and address. The diagnosis I already had, so the breach of professional confidence was complete. He told me that he would make an immediate authorization as a "life-saving measure" while the matter was referred to these mysterious advisers. When I told him that they had already decided, he rescinded his decision, but when I further reminded him that the phrase "life-saving measure" was his own he changed his mind again, and the issue is now as far as I know, again authorized pending some undefined further decision.

It does seem intolerable that when these "advisers" decide against an application on behalf of a patient that they have never seen action can be taken to implement their decision without further reference to the doctor concerned, that one should have to disclose confidential details to a completely unknown layman, and incidentally that one should have to spend a sum considerably greater than even the new capital fee on telephone calls to obtain the bare necessities of life for a desperately ill patient. And it would appear to bode ill for anyone rash enough to suffer from this complaint after Jan. 1, 1948.—I am, etc.,

Gl. Yarmouth.

H. DE B. MILNE.

### Homosexuals

SIR,—May a schoolmaster with some knowledge of history be permitted to comment on the concluding paragraph of Mr. Stanley-Jones's letter (Oct. 25, p. 671)? It is difficult to recognize in his description of Innocent III as "a repressed homosexual and a fanatical persecutor" the subject of Prof. E. F. Jacob's brilliant opening essay in the sixth volume of the *Cambridge Medieval History*. Mr. Stanley-Jones's conviction that the Albigensians and Bogomils were engaged solely in a quarrel with the Church of Rome looks odd after reading, for instance, the views of a scholar of international repute such as Prof. Jean Guiraud, a useful summary of which may be found in the third volume of *European Civilization* (Oxford University Press, 1935).—I am, etc.,

York.

T. CHARLES-EDWARDS.

### Refraction Testing

SIR,—It is a strange suggestion that a medical man should be invited to prescribe spectacles for a visual disability if he lacks adequate specialist knowledge to investigate other possible causes, or that, being recognized to possess such knowledge, he should abstain from applying it. These are the only logical interpretations to be placed upon the recommendation of lesser sessional rate of remuneration for "clinical refractive work" than for specialist examination, and for countenancing the evasion by local education authorities of liability in respect of children attending a hospital eye department "solely for the prescription of spectacles." The estimate of error of refraction and of the possible benefit to be conferred by spectacles is by a part of ophthalmic specialist examination; the desire of the patient or of others to elicit a prescription for glasses cannot absolve a doctor of responsibility to apply special medical knowledge of eye conditions or warrant a cheap or gratuitous "semi-specialist" service.

A patient consults a doctor for his opinion and advice, and although this may be expressed in relation to pharmaceutical means the attendance is not "solely for the prescription of a bottle of medicine." The representatives of the profession cannot recognize any such suggestion of limited application of the skill of its members, bearing the implication of a "dual standard" or worse. It is legitimate to establish certain qualifications of experience and training to merit recognition in special fields; it is paradoxical to suggest that the eyes of each school

child need specialist ophthalmic care, and yet to approve a less-than-specialist rate of remuneration for "clinical refraction" (whatever that may mean) as something apart from specialist ophthalmic examination. As a part of such examination the specialist may—and in the future will—delegate it to others adequately trained in that routine procedure, and correlate their findings with his in determining further conduct, including the prescription of spectacles if indicated. In a special matter affecting so important an organ no doctor can feel happy in advising the use of an appliance without specialist opinion of its suitability.

From recent correspondence in these columns on the subject of amblyopia, however, it seems that a few doctors are insufficiently aware that squint in children seldom arises from error of refraction alone; that in its inception there are commonly parietic and other factors, sometimes transient but often persistent; that attempted cure by spectacles, however apt, will fail in a large number of cases; and that by delay in examination or by misplaced confidence in spectacles alone opportunity may be irrevocably lost at an important period in visual development, especially in infancy and the pre-school years.—I am, etc.,

Hull.

D. STENHOUSE STEWART.

### Contact Lenses

SIR.—I think that it is right to point out that the remarks of Mr. A. Seymour Philips (Sept. 20, p. 469), based on the experience of a number of patients, present a more correct estimation of the results of wearing contact lenses than do those of Dr. C. Peter Warren (Oct. 11, p. 589), derived from his personal experience, satisfactory as that may be. A survey of a large number of patients who have been fitted with contact lenses has recently been carried out, and the results, which will be published in full elsewhere, show that about one-third of all patients fitted no longer wear their lenses. The careful preliminary estimation of each patient's suitability for contact lenses is essential to reduce the percentage of disappointments.—I am, etc.,

London, W.1.

A. G. CROSS.

### Planning and World Population

SIR.—I have always found it difficult to understand why such people as Dr. G. E. Paul (Oct. 11, p. 589) put man's sexual functions in a category entirely apart, when to the average person they would seem no more important than the functions of self-preservation and nutrition, for instance. Surely it would be equally logical for Dr. Paul to state that one of man's functions made known to him by his reason is self-preservation, and two of the organs most involved are the eyes, so that any act where they are used exclusively for pleasure, such as reading a good book or visiting the theatre, is intrinsically evil, because self-preservation is temporarily ignored. Using a similar argument, eating or drinking substances which give pleasure, but do not nourish and so temporarily frustrate the true purpose of the digestive glands, becomes intrinsically evil also.

Perhaps those who hold the same views as Dr. Paul perform no action which does not fulfil a basic function. If so, I admire their intensity of purpose; the world would undoubtedly be a better place if there were more like them, but I doubt if it would be happier.—I am, etc.,

Islip, Oxford.

J. L. BOLDERO.

### Student Health

SIR.—Your readers may be aware that the British Medical Students' Association has been discussing the problem of student health for the past two years. At the last Annual General Meeting in London the following resolutions were made:

That the B.M.S.A., taking into account the hazards to which clinical students are exposed and bearing in mind the facilities which already exist in all teaching hospitals, views with concern the absence of any compulsory medical examination for clinical students on admission to hospital. The B.M.S.A., therefore, recommends very strongly that all schools which have not already done so should with the least possible delay arrange regular compulsory medical examinations for all their clinical students.

That the B.M.S.A. recommends that every University should appoint a full-time medical officer who, together with such assist-

ance as may be necessary, should be responsible for the routine compulsory medical examination of all matriculated students with the dual object of raising the standard of student health by giving advice and of obtaining information about the student morbidity rate and its relationship to the varying factors in university life.

Compulsion was agreed on after considerable discussion because the delegates from all over the country realized that voluntary student health schemes, where they existed, have left a good deal to be desired. It must be further pointed out that entrance to university will in no way be influenced by medical examination, as this will take place after students have already matriculated. It is hoped that the first resolution will be acceptable to many schools in the very near future. The second resolution will be sent on to the National Union of Students and the Scottish Union of Students with the hope of formulating a united student policy on this important problem.—I am, etc.,

Edinburgh.

S. M. DRANZ,  
President, B.M.S.A.

### Road Accidents

SIR.—The paper by Dr. Kenneth Soddy (Oct. 18, p. 623) on the psychological aspects of accidents is interesting and no doubt scientifically valuable, but it appears to me somewhat remote from the immediate problem. I have before me a newspaper cutting of to-day's date of police court proceedings in which a driver was fined £5 and his licence not suspended following an accident in which a pedestrian was run down on a crossing and his body thrown 20 ft. Independent evidence was given that the crossing was clearly visible, and a bus driver estimated the speed of the car at between 35 and 40 m.p.h. in a busy street.

The truth is that nearly everybody in authority is a motorist, including magistrates, and the law in consequence is not adequately enforced. Motorists have got into the habit of throwing the onus of avoiding accidents upon the hapless pedestrian, including the young and the aged, who are the chief victims, instead of constantly bearing in mind that they are in charge of a potentially dangerous machine that it is their responsibility to keep well under control. The short-term solution is low speed and strict law enforcement under the present-day conditions of mixed traffic. The long-term solution is segregation. This is the policy of this association.—I am, etc.,

London, S.E.24.

T. C. FOLEY,  
Secretary, The Pedestrians' Association.

### Future of Almoners

SIR.—Next year the financial functions of hospital almoners will come to an end. It is to be hoped that they will then be able to devote more time to the needs of long-term patients, sometimes known as the "chronic sick." Such cases often require considerable help to adjust their circumstances to the conditions arising from their illness when this lasts months or years, not weeks. Payment for tenancy of rooms may need settlement; business affairs often require some attention; legal advice may be necessary. None of these matters can be conveniently managed from a hospital bed. In these days, when some hitherto incurable disease can be treated with a certain amount of success, it may be necessary to find a home or lodging for the patient on discharge. At present the "acute" short-term case has almost monopolized the attention of the almoners.

After they have been parted from their money bags they will need to spend more time with the long-term sick; for only by assisting in the rehabilitation of the despised "chronic" will they be able to play their part in relieving the congestion in hospital beds which now so sorely afflicts this country.—I am, etc.,

London, S.W.11.

TREVOR H. HOWELL.

### Qualifications and Remuneration of Specialists

SIR.—It would appear self-evident that the appropriate qualification for a psychiatrist is a qualification in his own specialty. Certainly his study of psychiatry should be founded upon a sound knowledge of general medicine. Perhaps the standard of the D.P.M. has not always been consistently high, but are these good reasons for taking the M.R.C.P.? Experience has shown that a high proportion of the psychiatrists

who take the M.R.C.P. become interested in the physical aspects of mental illness to the exclusion of the psychological side. To hold the higher qualification essential to the general physician is surely not the hallmark of the psychiatrist. It merely proves he has spent a period of study (probably two years or more) away from his own specialty.

A sound knowledge of general medicine is equally essential for any other specialist. Are surgeons or gynaecologists to take the M.R.C.P.? I submit that academic distinction is only one of the qualifications of a specialist. Experience and ability are equally important.

Those who advocate varying scales of remuneration for specialists in different branches of medicine advance all manner of "reasons" for this. The two favourite arguments are (1) responsibility and (2) alleged amount of work done as assessed by annual turnover of patients. Anyone who has practised psychiatry in a busy observation ward will agree that the responsibility is great. Decisions affecting the liberty of the subject are part of the daily routine. Decisions involving the safety of the general public are frequent. Responsibility for the patient's life arises frequently in a variety of ways. If the "turnover" theory is to be applied logically the assistant throat surgeon performing several thousand tonsillectomies per annum should be more highly remunerated than the senior general surgeon performing only a few hundred major operations in the same period.—I am, etc.,

Birmingham.

F. A. BLEADEN.

### Spinal Pumping

SIR,—In the *Journal* of July 12 (p. 62) there appeared an annotation on "Spinal Pumping" which could be construed as meaning that an "iron curtain" on medical information exists between Eastern and Western Europe, and a complaint that Speransky's work had been buried in the Russian language. I am much further away from this "iron curtain" (which was invented by Goebbels and resurrected by Churchill) than the author of the annotation, but find that all the evidence *re* this figment of a Nazi's imagination is negative: there is no iron curtain.

The simple expedient of perusing the *B.M.J.*, for instance, informs me that there was recently (June 27) a meeting of the European Association of Clinical Pathologists at Cambridge, where for one country at least behind the "iron curtain"—Czechoslovakia—there was a representative. On July 26 there was an International Congress for Microbiology in Copenhagen, where "most other European countries [than Scandinavia, England, France] were represented." From June 24 to 28 there was the Medical Women's International Association at Amsterdam, which included delegates from Finland, Poland, Hungary, and Czechoslovakia; and from July 21 to 25 the International Physiological Congress was held, at which delegates from Hungary and the U.S.S.R. were present. Again, there is no difficulty in subscribing to Soviet medical journals, and to such papers as *American Review of Soviet Medicine*, *Soviet Weekly*, and *Slavonic Review*, which contain a fair selection of contemporary Russian medical work. And how did the geniuses of the *Bulletin of War Medicine* penetrate this opaque "iron curtain"? One is driven to suspect Soviet agents at work in the most apparently innocent places.

Finally, later communications showed that Speransky's work and ideas were by no means buried in the Russian language but were known to those who had intelligence and lack of prejudice enough to find out whether they really were available before they started to ape the gibberish of the Hitler Propaganda Ministry. How would we feel if the Russians accused us of burying our medical works in the English language instead of being jolly gentlemen and sedulously translating every word we write into Russian? Apart from thinking them to be madmen, we would consider them damned impudent, and rightly so—I am, etc.,

Perth, W. Australia.

L. R. JURY.

### A Protest

SIR,—I was amazed to read in a daily newspaper of a British doctor being taken to the assizes for throwing a brick through the shop window of a Jewish citizen of this country. It is a most terrible blot on the medical profession in this country,

and brings back to all who read such a thing memories of typical Nazi actions of the German doctors during the Hitler regime. If we in our profession act as typical thugs, our profession is lost. This action of the above doctor requires most severe reprimand from the profession. To-day is the time to uphold the dignity of our calling, not to insult it.—I am, etc.,

Preston, Lancs.

A. E. BERNSTEIN

## POINTS FROM LETTERS

### What is Male Climacteric?

Dr. C. L. MALHOTRA (Sarangarh) writes: There has been a good deal of talk about the male climacteric. The female climacteric is a well-known and recognized entity, with definite symptoms, age onset, aetiology, and to all intents and purposes the cessation of pregnancy, barring exceptions, the last being the most important. In the male climacteric, so-called, this last factor is wanting. There is no age beyond which a man can be said to be infertile. Nor does the desire vanish with age. . . . The enlargement of the prostate gland in the male, associated with increasing years, is fact said to increase the desire. Wherein lies the male climacteric then? It would appear more probable that in late middle life the fighting male may suffer from the effects of the fight—a variety of nervous depletion or fatigue, which he ascribes to the male climacteric. It may also be that the male does not desire to be excellent by the female in having one disease less.

### Sodium Bicarbonate as an Antiseptic

Dr. HEDDA GORZ (Polish Hospital, Storrington) writes: During the insurrection in Warsaw we were very short of all drugs, particularly of antiseptics. We used a solution of 5% sodium bicarbonate for dressing of wounds as well as for operation. The results appeared to be excellent. All of us were greatly satisfied of obtained results and I used it afterwards in my further practice. . . . For two months the patients were treated in cellars and other very inadequate conditions without water and drugs. Working in such terrible conditions—field hospitals arranged in cellars and underground shelters—patients whose wounds were open, dirty, and contaminated with dust of the bombed houses were only treated with the 5% solution of sodium bicarbonate, the only one obtainable there. All heavy cases in badly ventilated cellars became tolerable after dressing with the solution, even open lung wounds notorious for their fetor as we known to every surgeon. . . .

### Australian Chapel of Remembrance

Major N. KEITH BUSHELL (late No. 3 Australian General Hospital of Harefield, in Middlesex, there lie the remains of 110 Australian soldiers, sailors, munition workers, and one Australian nursing sister. These died from wounds and sickness in No. 1 Australian General Hospital, which was stationed in Harefield in the first world war and many of them were badly wounded men from Gallipoli in 1915. These graves have been cared for by the Imperial War Graves Commission and the devoted ministrations of many of the Harefield people. . . . The almost inevitable outcome of this true spirit of imperialism, inspired by the late head master of Harefield and so well fostered by the present vicar, is the representative Australian desire that a chapel in the old and historic church of Harefield should be converted into an Australian chapel of remembrance to cover both the world wars. An executive committee has since been formed for this purpose, and I am honoured by being asked to act as the hon. sec. and treasurer of it. In order that this chapel of remembrance may be made beautiful in quality and Australian in feature, it is necessary to appeal for no less a sum than £5,000. Any contributions that English friends care to send will be welcomed and appreciated, but this appeal is made primarily to Australian residents in Britain, and especially to those who were with the Australian Imperial Forces in the first world war. Contributions to this fund should be addressed to me c/o the National Bank of Scotland, 18-20, Lower Regent Street, London, S.W.1, when they will be officially acknowledged.

### Warm Houses

Dr. G. C. PETHER (Hadley Wood, Herts) writes: With cuts in our rations it is surprising that more thought is not given to the possibility of keeping our houses warmer while reducing our heating bills, both for coal and for food. In an experimental house the provision of a small air space and wood panelling made an enormous reduction in the time required to bring the wall temperature up to the room temperature. Under standard conditions the period fell from 9 hours to 20 minutes. It is not often realized that in heating up the walls unnecessarily we lose comfort and also money. Similar economies are possible if double windows are fitted and heat losses through roofs are cut down. I think the dietitians might take heart and think of indirect means of reducing our calorie requirements

## Obituary

### W. ROWLEY BRISTOW, F.R.C.S.

Mr. Walter Rowley Bristow, orthopaedic surgeon to St. Thomas's Hospital, died in a London nursing-home on Nov. 10 at the age of 64.

Mr. Rowley Bristow was a student at St. Thomas's Hospital. He took the conjoint diploma in 1907, and graduated M.B., B.S. a year later, going on to take the F.R.C.S. in 1909. As a student he played regularly in the soccer, lawn tennis, and water polo teams. After holding a number of house appointments, including that of house-surgeon to Sir George Makins, he decided to devote himself to traumatic surgery. During the 1914-18 war he began his long connexion with the Army, serving first as R.M.O. with the Middlesex Yeomanry in Egypt and Gallipoli. He was mentioned in dispatches for his services at Suvla Bay. In 1916 he was appointed surgeon at the Military Orthopaedic Hospital at Shepherds Bush, where he first became interested in some of the applications of electrotherapy and where also he began his long friendship with Sir Robert Jones, who was then his chief.

As part of the post-war scheme of reconstruction at St. Thomas's in 1919 an orthopaedic department was established with Sir Robert Jones as titular head. Bristow was elected as his assistant, but was in fact from the start its real director. He continued his connexion with the Shepherds Bush Hospital, remaining as consulting surgeon after it had been handed over by the War Office to the Ministry of Pensions. His growing reputation led also to his appointment as consultant to the King Edward VII Convalescent Home for Officers and to the Orthopaedic Hospital, Pyrford, among other hospitals. His connexion with Pyrford provided a valuable addition to the limited facilities at St. Thomas's, and it became virtually a county annexe for orthopaedic patients. The Royal College of Surgeons elected him Hunterian Professor in 1935; when he took as his subject "Internal Derangement of the Knee-joint." He also gave the Hugh Owen Thomas Memorial Lecture in 1937, and in the same year was president of the British Orthopaedic Association, of which he was one of the founders. In the recent war he was consultant in orthopaedic surgery to the Army, with the rank of brigadier, and was largely responsible for the establishment of efficient orthopaedic services in every theatre of war. He was at one time president of the Orthopaedic Section of the Royal Society of Medicine, and he had been vice-president of the Section of Orthopaedics at the annual meetings of the B.M.A. in 1931 and 1932. He was a corresponding member of the American Orthopaedic Association and an honorary member of the French and Belgian Orthopaedic Associations. He married, in 1910, Florence, the only daughter of Dr. James White, LL.D., and had one son and two daughters.

We are indebted to Mr. George Perkins for the following appreciation: By the death of W. R. Bristow, known to thousands as Rowley and to his intimates as Walter, English medicine has lost one of its most colourful personalities. A link with the past has been severed, for essentially he belonged to the pre-war era. Wherever he went and whatever he did, his presence was felt. Like Dr. Johnson, he craved for company and fully repaid his audience for their society. No. 102 was, at least to one of his admirers, like no other house in Harley Street, because Bristow lived there, and live he did. No one ever enjoyed life more. Not for him the sedate backwater of a university city: the hurly-burly of busy London was his purlieu. He breakfasted at 8.0 and was in his office by 8.30. From then until 7.30 in the evening, with a break for lunch, at which there was never less than one guest, he worked at top pressure, expending his own depthless energy and exhausting that of his secretaries. There followed a champagne cocktail and a change for dinner. Dinner was an occasion. He had one of the best cooks in London, and could talk intelligently to any *chef de cuisine* on his own subject. When he was told the nature of his fell disease, he received his sentence of death with philosophic resignation. "Well, I have had a damned good life," he said; and how true it was.

As a host he was in a class apart. He had the knack of making the humblest of his guests feel that he was important, and no one can do that who does not love his fellow men. His attributes were legion. He was a scratch golfer, a good shot, an ardent fisherman, and a good bridge player, and although his opponents did not always agree with his own estimate of his prowess he usually won.

As a student he was remarkable for getting through his examinations without doing any work. As an orthopaedic surgeon he was remarkable for knowing the latest work without doing any reading. After he had been invalidated home from the Middle East in the Great War he came in contact with Sir Robert Jones. There followed a firm friendship broken only by Sir Robert's death. In the late war he did what Sir Robert would have done had he been alive. Many consider that Bristow's best work was done during this period. He threw his heart and soul into the establishment of an efficient orthopaedic service for the Army, and personally recruited most of the surgeons. The casual way in which his services were officially recognized demonstrates how much was expected of him. That Rowley Bristow could and would do it was taken for granted. During his years as president, the British Orthopaedic Association flourished as never before. Those members who went with him to Scandinavia were proud of their leader. But as an orthopaedic surgeon his loss will be felt most by his innumerable patients, and by members of the orthopaedic department that he created at St. Thomas's Hospital. All his life the hospital came first. His views did not always coincide with those of his colleagues, yet none of them doubted but that his actions were intended to add to the lustre of the hospital he so truly loved.

It is natural for his alumni to venerate his memory, for no one could have had a more loyal chief. He backed up his juniors through thick and thin, and accepted the blame for all their mistakes. He went out of his way to advance all who had trained or worked under him. Many of his juniors have reason to remember his generosity. Nobody is missed for long, but those who knew Bristow will cherish his memory for as long as they live.

G. R. G. writes: Walter Rowley Bristow will be most sorely missed, for he was a man of remarkable and altogether delightful character, endowed with outstanding vigour and zest for life and fellowship. He was the central figure of a great group of friends which included all his colleagues and many of his patients. He will be very gravely missed by orthopaedic surgeons all over the world, for when he and Robert Jones came together in the first world war he found his true vocation and soon became one of the most eminent orthopaedic surgeons, trusted universally for his sound judgment, ability, and sincerity. He taught well, penetrating to the heart of his subject and picking on the essentials with clarity and emphasis. His out-patient clinics at St. Thomas's were stimulating, memorable, and crowded. They were alive with humour and humanity, for he never failed to feel and show a friendly intimacy with the Lambeth folk. In the war he gave splendid and unsparing service, especially in developing a first-class orthopaedic organization in the Army. A conscientious student of everything he took up in work or play, he quickly made himself master of style and craftsmanship; his keenness was infectious, his influence admirable, his presence a joy. He has left us while still at the height of his powers.

### SIR ROWLAND MALLETT, M.D.

Sir Frederic Rowland Mallett, for thirty-six years an honorary consulting surgeon of the Bolton Royal Infirmary, died suddenly on Oct. 29 at his home at Minchinhampton, Gloucestershire, at the age of 78. He was educated at Rossall and Edinburgh University, where he graduated in 1891, proceeding M.D. five years later. He was appointed to the staff of the Bolton Royal Infirmary in 1893. This appointment continued a remarkable family record of unbroken service which, including that of his father and his grandfather before him, totalled 113 years. Sir Rowland always took a keen and active interest in medical and surgical matters, and particularly in the welfare and activities of the Bolton Royal Infirmary, of which he was appointed president in 1929.

Unfortunately he had to relinquish this post in 1945 owing to ill health.

In addition to his professional duties he undertook much public work. He was honorary secretary of the local medical war committee in the 1914-18 war. He was a member of the town council for many years, chairman of the Bolton Division of the B.M.A., 1926-8, chairman of the Local Medical and Panel Committee and of the Bolton Division of the British Red Cross Society, and he held many other posts. He was knighted in 1934, the year before he went to live in Minchinhampton, in recognition of his long and devoted service to the Bolton Royal Infirmary. His outstanding characteristics were his sound judgment not only in his professional work but in all matters, his unswerving loyalty to duty, his patience and courtesy in all circumstances, and his interest and sympathy in human affairs. All these endeared him to a host of friends, and no man was more respected in the town in which he was born and worked for most of his life.

He married in 1901 Mary Constance, daughter of Mr. C. W. Dixon, and had one son and three daughters.

Dr. ARNOLD GREGORY died on Oct. 31 at the age of 68. The son of a Congregational minister, he qualified M.R.C.S., L.R.C.P. in 1902. After holding house appointments at the Leeds Infirmary and Ida Hospital, he came to Manchester in 1906 as a general practitioner. During the 1914-18 war he served in the R.A.M.C., chiefly in India, where he contracted malaria. A member of the British Medical Association since 1907, he served for many years on the local executive committee, and was a representative in the Representative Body from 1929 to 1939, and from 1941 to 1943. He was a member for eleven years of the Charities Committee, and he used every opportunity to further its activities. He was on the Local Medical and Panel Committee for many years, acting as its honorary treasurer from 1927 to 1945. A member of the Manchester Medical Society from 1906, he served on the committee for two periods, and became a vice-president in 1930. In 1935 he was president of the Society—a rare distinction for a general practitioner. He was keenly interested in medical education and its application to general practice, and made this the subject of his presidential address to the Manchester Medico-Ethical Society. He was always especially interested in the patient's point of view and in the welfare of chronic invalids. He will be sorely missed by his patients, as also by his fellow practitioners, whom he has served so faithfully and well. He leaves a widow, a daughter, and three sons, two of them members of the medical profession.

Dr. HUGH MCKERLIE died on Sept. 28 at his home in Manchester at the early age of 47. He had been ill for many months but had recovered sufficiently to resume work, when a sudden haemoptysis put an untimely end to a busy and useful life. After his early education in Dumfries he entered Glasgow University and qualified in 1921, graduating M.B., Ch.B. a year later. He held a resident appointment at Wakefield before starting general practice in Manchester. Full of common sense and ability to get on with all sorts and conditions of people, he had a sound knowledge of his work and soon built up a large practice. He devoted considerable time to the interests of the profession, serving for the last ten years as secretary of the Manchester Panel Committee, and being also on the Manchester Insurance Committee and attending many panel conferences. He was also chairman of the Manchester Division of the B.M.A. from 1939 to 1943, and a member of the local Medical War Committee. His death is a great loss to his colleagues, his patients and friends, and most of all to his two sons.

Dr. WILLIAM HAIG died at Crieff on Nov. 2 at the age of 76. Dr. Haig had conducted an extensive general practice in the area for forty-three years, retiring only in 1942. Of a quiet and retiring disposition, his human understanding and many kindnesses made him a well-loved and respected figure in the district. He was a student at Edinburgh and graduated in 1894. A cousin of the great Field-Marshal, Dr. Haig served with distinction during the 1914-18 war, reaching the rank of major and being awarded the D.S.O. For a number of years after the war he was president of the local branch of the British Legion. During the second world war he acted as welfare officer for all the troops in the Crieff area, and for most of that period was chairman of medical boards for Perthshire. He was honorary physician and surgeon to Crieff Cottage Hospital, and had many other interests. He was senior elder

in St. Michael's Parish Church, Crieff; had held high office in Freemasonry; was one of the oldest members of the Ancient Order of Forestry and official surgeon to that body, a member of the local committee of the Overseas Club, a strong U.S.A. and in his younger days an enthusiastic member of the golf club. He was keenly interested in the local Ambulance Brigade, having been its lecturer for many years. Dr. Haig was a member of the B.M.A. for fifty years, and had held the following offices: representative in the Representative Body on thirteen occasions at intervals over the years 1909-39; member of the Insurance Acts Subcommittee (Scotland), 1928-30; president, Perth Branch, 1932-3; member, Scottish Committee, 1934-7; and he was also a member of the Charities Committee, 1937-8. He is survived by a brother and sister.

Dr. STEPHEN GREEN died on Oct. 31 after a long illness. He graduated M.B., Ch.B. in Manchester in 1906, and was a house physician at the Manchester Royal Infirmary. Later he held a house appointment in Winchester, and was resident medical officer at the Royal National Sanatorium at Bournemouth. He took the D.P.H. in 1906, and started his work in Portsmouth as schools medical officer before going to St. James's Hospital as a medical officer. He then joined his father, Dr. James Green, and his brother, Dr. Philip Green, in general practice. He was one of the Portsmouth doctors who remained there throughout the war and carried on his work through all the difficult "blitz" period. He leaves a widow and two sons.

## Medico-Legal

### MEDICAL EVIDENCE IN PENSION CASES

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The application of the law of war pensions has raised many difficult problems, especially of legal proof, and Mr. Justice Denning is to be respectfully congratulated on the patience and skill which he has brought to their solution, and on his comprehension of the medical issues involved. In the course of a recent appeal<sup>1</sup> he gave some useful directions to medical men who are asked for their opinions in disputes on whether a patient is entitled to a war pension or not.

A regular Army officer was taken to hospital in 1944 with cancer of the oesophagus, was sent to England, and died a month after the diagnosis had been made. His widow claimed the higher rate of pension given to a widow whose husband's death is due to war service. The tribunal had dismissed the claim. The learned judge explained that in cases where a man is passed fit at the beginning of his service but is later afflicted with a disease which leads to his death or discharge there is a compelling presumption in his favour, and to displace it the Minister must prove beyond reasonable doubt that the disease was not attributable to nor aggravated by war service. The evidence against the claimant must be as strong as that needed to convict a person of a crime. On the other hand, there is no need for it to amount to a certainty. If it leaves a remote possibility that can be dismissed with the sentence, "Of course it is possible, but not in the least probable," the case is proved beyond reasonable doubt.

Naturally in these cases much of the evidence is medical, and the judge emphasized that it is useless for a medical man to give an opinion that a disease is or is not attributable to, or aggravated by, war service without giving his reasons. Such an opinion involves not only his scientific knowledge but also his views on causation and on the meaning of terms such as "attributable" and "war service," which are matters for the tribunal and not for him to decide. He must not usurp the functions of the tribunal, but he should point out the probable or possible causes of the disease and of any aggravation of it, giving the degree of probability and then leaving the tribunal to decide whether on the facts the claim should be allowed. In cases where the aetiology is known, there should be little difficulty in stating the causes of the disease and of any aggravation of it, but cases where the aetiology is unknown or imperfectly known present great difficulty. If nothing else appears except that the cause is unknown, then it may be a cause incidental to war service and the Minister cannot prove

<sup>1</sup> *Miller v. Minister of Pensions*, 1947 2 All E.R. 372.

The general action of Bynin Amara is manifested by increased tone of the nervous, muscular, and cardio-vascular systems. It stimulates the digestive organs, improves the flagging appetite, corrects anæmia, and aids nutrition generally.

The marked asthenia and nervous depression which are prominent features of the post-influenzal state yield rapidly to its influence. Whenever there is any indication of lowered resistance a course of Bynin Amara is a valuable safeguard against infection.

## BYNIN AMARA

Containing Soluble Ferrie Phosphate U.S.P.N. 1.0; Copper Sulphate " " 0.2; Liquid Extract of Nux Vomica 0.93, Phosphoric Acid 0.2 per cent. w/v. Extract of Malt 60.0 per cent. w/v.

## NEW PLASTIC SURGICAL DRESSING

replaces bandages

**PRIMARILY** intended for fixing surgical prostheses to the skin, surgeons soon found other uses for Portex Plastic Skin.

**In Blood Transfusion**—to replace bandages and dressings.

**As a Surgical Barrier**—tested as a germicidal preoperative barrier, results exceeded all expectations. It was remarked that excoriating fistulae never supervened during operations in which they had been too common.

After this operation a further application effectively seals the wound and prevents excoriation of the skin by digestive ferments, which escape to the surface via the drainage tubes, etc., particularly following gall-bladder and gastric operations.

**General Uses**—"Portex" Plastic Skin is a handy and effective treatment for cuts and abrasions, small burns, mosquito and other insect bites, pruritus, cracked nipples during lactation. Free samples and literature from the manufacturers, Portland Plastics Limited, 6, Victoria Street, London, S.W.1.

## "PORTEX" PLASTIC SKIN

Formula: Phenyl Salicylate gr. xii, Methyl Methacrylate gr. xvii, Resorcinol gr. ii, Eugenol m.l., Chloroform m.x., Volatile Solvents ad 3ii.

In tubes and in 25 c.c., 56 c.c., 156 and 600 c.c. bottles.

## ANAHÆMIN B.D.H.

Anahæmin B.D.H. has become established as a standard product for the treatment of pernicious anæmia. Clinical use during more than a decade has provided abundant evidence of its erythropoietic potency, its comparative freedom from allergenic properties and its efficacy in preventing and arresting subacute combined degeneration of the cord.

Effective doses of Anahæmin B.D.H. are small in volume and, in maintenance, satisfactory doses may be given at relatively infrequent intervals.

Each batch of Anahæmin B.D.H. is clinically tested before issue.

*Further information is available on request.*

## A SINGLE\* SUPPLEMENT FOR SAFER PREGNANCY

## Pregnavite

### CLINICAL USES

To improve the nutritional state where circumstances prevent consumption of all the protective foods required: to prevent hypochromic anaemia. Indications in the history of previous pregnancies: toxæmia, previous premature births, inability to breast feed, dental caries.

\* The recommended daily dose provides: vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B<sub>1</sub> 0.6 mg., vitamin C 20 mg., vitamin E 1 mg., nicotinamide 25 mg., calcium 160 mg., iron 68 mg., iodine, manganese, copper, not less than 10 p.p.m. each.

Upper Mall, London, W.6

# SEVERE BURN (Area 162 sq. inches)

A treatment using tulle gras, pressure dressings and plaster fixation

Fig. 1

Fig. 2

**CASE HISTORY**—The patient, a young man, was admitted to hospital, having been burnt by an electric blanket. The raw area measured 162 square inches. Excision of the burnt area was performed on the same day. Tulle gras (Jelonet) was applied. Fixation by Gypsona plaster of Paris bandages applied over the whole area, abdomen and thigh. The patient was given a blood transfusion. Seven days later, the affected part was covered with thin razor grafts from both thighs and a pressure dressing of Elastocrepe applied. Fixation was again secured with Gypsona plaster of Paris.

The patient was discharged to duty 7 weeks later.

The details and illustrations above are of an actual case. T. J. Smith & Nephew Ltd., Hull, manufacturers of Elastoplast, Elastocrepe and Jelonet, are privileged to publish this typical instance of the use of their products with success in the belief that such records will be of interest.

Fig. 3

## Nature provides, but . . .

In these days of reduced and monotonous diet, the winter months are the 'testing time' for those of the population suffering from vitamin deficiencies. Of these deficiencies the most important are those of the B-complex which are often 'subclinical' and manifest themselves only by loss of appetite, increased liability to infection and by tendency to fatigue, irritability and lowered morale.

Elixir 'Virvina' provides adequate amounts of the essential factors of the vitamin B-complex together with the glycerophosphates of calcium, manganese, sodium and potassium. Its extreme palatability renders Elixir 'Virvina' acceptable even to the most fastidious of patients.

Elixir 'Virvina' is supplied in 4 oz., 16 oz. and 80 oz. bottles. Descriptive literature will gladly be supplied on request.

Each fluid ounce of Elixir 'Virvina' contains:

Thiamine hydrochloride (Vitamin B <sub>1</sub> )	4.0 mg. (1332 I.U.)	Pyridoxine hydrochloride (Vitamin B <sub>6</sub> )	0.1 mg.
Riboflavin (Vitamin B <sub>2</sub> or G)	2.0 mg.	Nicotinic Acid Amide	30.0 mg.
		Calcium, Sodium, Potassium and Manganese glycerophosphates (total)	6.625 grains

**'VIRVINA'**

that it is not. That is what once happened in a case concerning Hodgkin's disease. In many cases, however, although the aetiology is unknown, experience and statistics are able to throw light on the circumstances in which the disease arises or develops. For instance, although the precise cause of schizophrenia is unknown, experience shows that in the great majority of cases it is essentially independent of external circumstances, and that therefore in a given case the probability that it is not attributable to war service may be high enough to defeat the strong presumption in favour of the claimant. On the other hand, if there is a reasonable suggestion that any incident of war service, such as exceptional strain immediately before the onset of the symptoms, may have played a part, the claim may succeed, because statistics show that in a minority of cases schizophrenia has been preceded by severe stress.

The little knowledge of the cause of cancer possessed by medical men is based on experience and statistics. The high incidence of carcinoma of the scrotum in chimney-sweeps warrants the inference that the irritation of soot plays a part. No such observation, however, supported the present claim. One medical witness thought that this cancer might have resulted from the irritation of sand swallowed in the Middle East, but other experts dismissed that idea as highly speculative and quite outside the bounds of probability, because of the rarity of cancer of the oesophagus in men serving in the desert. Another suggestion, that it might have been due to the drinking of spirits or of excessively hot liquids, was rejected on the ground that oesophageal cancer is predominantly a male disease and that these habits are not confined to men; in any event these habits are personal ones and not attributable to war service. For the Minister it was stated that for all practical purposes cancer is not regarded as infectious or contagious, and that cancer of the oesophagus is not related to employment or environment. Moreover, only 45 cases in Service men were reported over the period of the entire war—7 cases a year against the 1,700 known to occur in the whole country. There remained the doubt, due to the unknown aetiology of cancer, that war service might have played some part. One expert said that he could not state with any degree of certainty that Service factors had played no part, and another said that he could not assert that nothing whatever in the environment had had an influence in causation.

The tribunal had come to the conclusion that the whole of the probabilities were that war service played no part. There had been a possibility the other way, but they had dismissed it as too remote. That was a reasonable conclusion to come to, and so the judge held that they were right and dismissed the appeal.

## The Services

The following officers have been awarded the Efficiency Medal (Territorial): Lieutenant-Colonel T. W. Preston, Major (now Lieutenant-Colonel) W. H. Wolstenholme, O.B.E., Captain (now Major) J. R. Hamerton, and Captains (Honorary Majors) D. P. Holmes and J. A. Reid, R.A.M.C.

### DEATHS IN THE SERVICES

Lieut. ALEXANDER MCKENZIE ELLIOTT, recently R.M.O. of the 3rd Battalion, Parachute Regiment, 6th Airborne Division, died on Oct. 7, as the result of an accident, at Haifa Military Hospital, Palestine. Lieut. Elliott, who was 25, graduated M.B., B.Ch., in 1945. He was a student at Cambridge University and after qualifying he held a senior house appointment at Hope Hospital, near Salford, before being commissioned in January of this year.

A circular from the Department of Health for Scotland has been sent to local authorities asking them to submit to the Secretary of State proposals for discharging their functions under the National Health Service Act. The proposals must be submitted by specified dates, the last of which is Feb. 28, 1948. The circular urges local authorities to hold consultations with Executive Councils, Regional Hospital Boards, and voluntary organizations as soon as possible, and suggests the joint establishment of advisory co-ordinating committees for suitable areas.

## Medical Notes in Parliament

### Discussions with the Minister

On Nov. 13 Sir HENRY MORRIS-JONES asked the Minister of Health whether he would make a statement on the result of his negotiations with the representatives of the medical profession on the terms and conditions of service under the National Health Service Act, 1946. Mr. BEVAN replied, "The time to decide that is when the discussions are complete."

Sir ERNEST GRAHAM-LITTLE had asked on Nov. 10 for an estimate of the number of general practitioners and of specialists which would be required to warrant putting into operation in July, 1948, the National Health Service Act, 1946. He further asked what measures had been taken to provide additional hospital accommodation, health centres, and other buildings required to carry out the provisions of the Act.

Mr. BEVAN replied that the National Health Service would be brought into operation with the resources available at the appointed day. These resources would be extended as circumstances permitted.

### Calories

Major LEGGE-BOURKE inquired on Nov. 10 how the daily calorie content of the weekly minimum amount of food regarded as necessary for an unemployed man, as decided by the Ministry of Health in co-operation with the British Medical Association in 1933, compared with that of the present ration after the reduction recently announced by the Government.

Mr. STRACHEY said that the calorie value of the No. 2 diet suggested for an adult man by the British Medical Association in 1933 was 3,386 calories daily. As announced by the Minister of Economic Affairs the recent reduction in distribution would result in an estimated average daily calorie intake of just below 2,700 per head for the whole population. This took into account the rationing of potatoes. The cut in potato consumption represented 70 calories.

Mr. Strachey stated on Nov. 11 that the present calorie values of rationed foods for a normal adult were:

Meat	..	..	..	..	..	..	..	117
Bacon	..	..	..	..	..	..	..	15
Cheese	..	..	..	..	..	..	..	33
Butter	..	..	..	..	..	..	..	61
Margarine	..	..	..	..	..	..	..	124
Lard	..	..	..	..	..	..	..	36
Sugar	..	..	..	..	..	..	..	123
Bread	..	..	..	..	..	..	..	648
Milk	..	..	..	..	..	..	..	102
Preserves	..	..	..	..	..	..	..	41
								1,300

These figures were the calories derived from the rations of a normal adult and did not include eggs nor points-rationed foods.

Asked by Mr. BUTCHER on Nov. 10 whether patients in hospitals and nursing-homes would suffer the recently announced cut in civilian rations, Mr. STRACHEY answered that residents in hospitals and nursing-homes were entitled to the same rations as the domestic consumer. Additional foods considered necessary on medical grounds could be obtained in the same way as for people suffering from similar complaints at home. Special cuts of 15% or 17½% in the allowance of various rationed and controlled foods to certain catering establishments made because of the crisis were not applied to residents in catering establishments or anyone in institutions.

### Cholera in Egypt

Sir HENRY MORRIS-JONES asked Mr. Bevin on Nov. 12 his opinion on a letter from the Egyptian Feminist Union accusing the British Army in Egypt of responsibility for the origin and dissemination of cholera.

Mr. BEVIN said this extremist attack was unworthy of a reply. It would only be believed by those already hopelessly prejudiced against Britain. The thanks of the Egyptian Government had been conveyed to him for what Britain had done against the outbreak. Besides the vaccine, over 60 ambulances had been made available, and also the services of Sir J. Taylor and Dr. Bruce White.

Mr. OSBORNE inquired on Nov. 12 why the squadron of heavy bombers which left Binbrook, Lincolnshire, aerodrome on a goodwill mission to the Turkish Air Force landed in Egypt on the outward journey in view of the presence of cholera in Egypt, and what was the cause of the death of one of the aircrew immediately on his return to this country.

Mr. ARTHUR HENDERSON replied that this squadron landed at an R.A.F. station in the Canal Zone of Egypt as part of its training programme. All members of the squadron were inoculated against cholera before leaving the United Kingdom. A member of the squadron died shortly after landing in this country. His death was due to the effects of lack of oxygen.

#### Proprietary Medicines

Asked on Nov. 11 by Captain FIELD to ensure a better use in the national interest of the labour and materials put into proprietary and quack medicines, Mr. BELCHER replied that drugs, chemicals, and other raw materials were allocated for the manufacture of proprietary medicines only when the needs of hospitals, doctors, and dispensing chemists had been met. Mr. Belcher hesitated to condemn such medicines generally. They made a useful contribution to the export effort.

#### Mental Illness

Mr. MICHAEL STEWART stated on Nov. 11 that 646 patients were in military hospitals suffering from mental illness. It was impossible to say in how many of these cases the condition might be regarded as due to war service. A decision on that was not taken till some time after admission, or, in many cases, not until after discharge. He added that the treatment of Service psychotic patients was well up to the standard of civilian hospitals.

**Petrol for Doctors.**—Mr. LESTER HUTCHINSON asked on Nov. 6 whether the Minister of Fuel and Power would allow medical practitioners, with a limited amount of time at their disposal, who had to be on call all day and every night, to use their cars for all purposes within a radius of ten miles of their consulting-rooms, to permit them some measure of relaxation and yet remain within speedy recall. Mr. GAITSKELL replied that this matter, on which he had received certain representations from the British Medical Association, was under consideration.

**Refresher Course.**—On Nov. 6 Mr. SOMERVILLE HASTINGS asked whether regulations existed under the National Health Service Act, 1946, for Regional Hospital Boards to arrange for refresher courses for any of those in their employ. Mr. BEVAN replied that such regulations were unnecessary. He said he would see that the Boards encouraged their officers to keep up to date by whatever methods were most appropriate. They would be able to allow leave with pay for attending suitable conferences and courses.

**German Doctors.**—Mr. HASTINGS was told by Mr. SHINWELL on Nov. 11 that 373 German doctors were employed in the United Kingdom to provide medical services for prisoners of war. These doctors received instruction in British health administration and in the British way of life.

**Regulation 33b.**—Answering Col. STODDART-SCOTT on Nov. 13, Mr. BEVAN said Regulation 33b would lapse at the end of this year. He did not propose to substitute any other compulsory powers but to encourage the use of persuasion to bring contacts under treatment.

**Smallpox.**—Mr. BEVAN states that on Nov. 13 there were no cases of smallpox in England and Wales. Since the year 1932 no death of an infant in England and Wales under the age of one year has been attributed to smallpox.

**Nystagmus and Dermatitis.**—In 1938 1,224 certificates of disablement were given by examining surgeons under the Workmen's Compensation Act for miners' nystagmus, and in 1946 1,297. Corresponding figures for scheduled dermatitis produced by dust or liquids were respectively 254 and 1,702.

**Unstable Adolescents.**—Mr. Chuter Ede is keeping in mind the contents of the report of the Joint Committee of the British Medical Association and the Magistrates Association on the problem of the unstable adolescent girl as it affects the Home Office in the continuous efforts to develop effective methods of treatment for such girls.

Sir George Henderson, Secretary of the Department of Health for Scotland, told members of the Northern Regional Hospital Board recently that both as a Board and as individual members their responsibility was to the Secretary of State alone. They were not appointed to represent—in the ordinary meaning of the word—any particular body or interest. Most of them had been appointed after consultation with various bodies and their names had been put forward by those bodies, but in their work on the Board they did not represent those bodies: they had been selected by the Secretary of State for the personal contribution which their particular form of knowledge and experience could help them to make. The fact that their collective experience had been so varied ensured that all necessary viewpoints could find expression. All that remained was that the various experiences should weld together in harmony.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

The following degrees were conferred on Nov. 1:

M.D.—R. T. Mummery, E. Clayton-Jones, C. R. T. Lane, W. A. Nichols, W. H. K. Willis, P. D. Scott.

T. Hoogstraaten, M.D., has been elected to a Frank Edward Elmo Fund Studentship, from Nov. 1.

### UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—O. A. N. Husain (with honours and distinguished in applied pharmacology and therapeutics), S. Adler, G. C. Ambrose, G. J. Amiel, G. W. S. Andrews, D. E. Argenti, D. A. L. Ashforth, A. W. Banks, A. F. Barnett, J. H. Baylis, R. W. Bazeley, Nancy Benstead, F. V. A. Bose, D. P. Bowler, P. R. Boyd, J. C. Brace, W. L. L. Brace, J. P. Bradshaw, D. J. Brewer, D. Brown, D. A. G. Brown, T. C. L. Brown, R. H. Browning, Alison M. Brydson, Joyce M. Buck, J. Bullough, R. A. Bush, A. W. H. Challis, M. S. Chayen, A. H. Cheshire, D. J. E. Cheshire, P. W. Clements, K. L. Cleminson, J. H. H. Clough, Pauline M. Cole, L. H. Collier, E. G. Cook, Olive Cooke, D. J. Cowan, D. H. Crook, A. D. Crown, S. P. Datta, D. W. Davies, W. M. Dixon, G. W. Downes, Wendy Dyer, K. C. Easton, C. D. Edwards, D. Edwards, L. R. L. Edwards, J. W. Ellis, J. Elvish, Angela I. Emerson, M. Ernest, J. W. G. Evans, M. P. Fiddian, D. H. Foddick, T. W. H. Forster, Dorothy P. Forsey, G. S. Foster, P. S. Gardner, C. D. Garat, E. Geiringer, P. Glasman, S. Goldwater, R. A. Goodbody, E. R. Griffiths, P. Griffiths, A. P. Grimby, H. J. Groves, G. J. Hadfield, E. Haigh, R. C. Hallam, S. J. Harris, Ursula M. Hay, J. L. Hayward, A. J. Heber, C. J. V. Helliwell, Mary Helmer, E. P. W. Helps, A. G. Henderson, S. R. Hewitt, A. W. Hind, Miriam Hirtzel, K. E. Hodge, G. R. Holby, P. K. Hopper, P. W. Hunt, R. J. Isaac, Pauline M. Jackson, M. A. K. Javid, B. A. G. Jenkins, D. H. Jenkins, M. S. Johnson, E. G. G. Jones, C. Jones-Morgan, W. A. J. V. Kilby, C. R. Knappett, A. Knudsen, F. K. Larkins, Joan Latham, S. Leigh, E. L. W. Leiser, L. L. L. L. Lim, Muriel J. Lowe, J. C. McDonald, N. J. C. McGill, D. I. Mackenzie, A. C. McLeish, R. I. Maitland, J. E. Mandel, F. B. Meade, E. W. Miles, B. C. Morgan, R. Morgan, J. B. Morrison, F. J. Napier, E. Neumar, R. D. Nicholson, E. G. Old, Susan H. Palmer, J. A. R. Parker, A. Paton, B. G. Pickles, A. Pilling, G. D. Pinker, W. A. Porter, Diana Powell-Colton, S. H. M. Price, Audrey K. Raistrick, R. L. Ray, D. M. Reader, Pauline Readman, E. J. Rich, R. W. Riddell, Adore H. Rider, E. Robinson, D. J. H. Rogers, R. H. Satchell, J. S. Scott, T. A. Shannon, D. A. Skan, B. C. Smith, H. Spira, J. D. Stevens, H. H. A. E. Tarnawski, P. W. G. Tasker, D. P. P. Thomas, W. R. G. Thomas, E. J. Trimmer, J. C. Turner, P. A. Tyser, G. F. Vaughan, P. J. F. Walsh, J. L. Warren, G. L. Whitmore, F. O. W. Wilkinson, D. W. Wilks, R. D. Willet, J. R. D. Williams, R. G. Williams, P. Wilson, G. Wiseman.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

Dr. R. M. Stewart, F.R.C.P., will deliver a Morison Lecture on "The Clinical Features and Pathological Anatomy of Infantile Hemiplegia" before the Royal College of Physicians of Edinburgh (9, Queen Street, Edinburgh) on Friday, Nov. 28, at 5 p.m.

A quarterly meeting of the College was held on Nov. 4, with the President, Dr. D. M. Lyon, in the chair.

Drs. H. M. D. Shepherd (Shanklin, I.O.W.), P. M. Wood (Hull), John Craig (Aberdeen), J. McG. Rogan (Glasgow), J. M. Macfie (Edinburgh), A. W. Wright (Edinburgh), Charles Cameron (Edinburgh), Neil Macmichael (Edinburgh), and J. A. L. Gilbert (Edinburgh) were introduced and took their seats as Fellows of the College.

Drs. J. D. M. Claessens (Capetown), J. M. Watt (Johannesburg), I. N. Sutherland (Edinburgh), G. Singh (Amritsar), R. O. Gillhespy (Paisley), J. G. Macleod (Edinburgh), G. M. Wilson (Edinburgh), R. S. Aitken (Aberdeen), and T. G. Brown (Hamilton, Lanarkshire) were elected Fellows of the College.

Drs. W. H. Rose (Ontario), K. G. W. James (Jamaica), A. S. R. Stewart (Shotts, Lanarkshire), Jack Rudolph (Pretoria), J. A. Ross (Rainhill, Lancs), J. B. H. MacArthur (Nottingham), J. H. L. Gilie (Dumfries), H. J. T. Ross (Kidderminster), W. J. G. Barrie (Edinburgh), W. G. MacDougall (Edinburgh), J. W. Rae (Larbert, Stirlingshire), K. K. Dacey (New York), E. M. Heller (Ontario), H. G. B. Richards (Cullercoats, Northumberland), J. K. Drummond (Dunbar), H. G. H. Houghton (Edinburgh), Nick Pedersen (Edinburgh), P. E. Brown (Bath), J. W. Buchanan (Barnton, Midlothian), M. W. Archdall (Lampeter), Thomas Black (Newcastle-upon-Tyne), G. B. Tait (Edinburgh), A. W. O. Taylor (Edinburgh), D. E. Williams (Edinburgh), Aneurin Hughes (Swansea), W. L. Sharp (London), Alexander Skene (Edinburgh), H. R. L. Fraser (Edinburgh), N. W. Horne (Edinburgh), J. B. Lowe (Edinburgh), H. D. Ross (Edinburgh), Erich Kahn (London), Malcolm Watt (Wellington, N.Z.), A. E. Claireaux (Edinburgh), J. W. T. Pretsell (Surrey), A. G. Harper (South Canterbury, N.Z.), T. McS. Wilson (Edinburgh), A. K. Das (Calcutta), H. C. W. Stringer (Christchurch, N.Z.), J. T. R. Russell (Edinburgh), and Constance C. Forsyth (Edinburgh) were elected Members of the College.

The Freeland Barbour Fellowship for original investigations carried out in the laboratory of the College was awarded to Lieut.-Col. W. F. Harvey, C.I.E., and the Wood Bursary to students commencing the study of medicine at the Edinburgh Medical School to Thomas Mercedith Chalmers.

## Medical News

### Nobel Prizes

The Nobel Prize for Chemistry has been awarded to Sir Robert Robinson, P.R.S., "for his research on important substances in plant biology, especially alkaloids." The physics prize has been awarded to Sir Edward Appleton, F.R.S., "for his work on atmospheric physics, and especially for his discovery of the Appleton layer."

### Royal Society Awards

The King has approved the recommendations of the Council of the Royal Society for the award of Royal Medals for the current year to Prof. C. N. Hinshelwood, F.R.S., for his distinguished work on the mechanism of chemical reactions from the simplest gas phase processes to the complexities of cell division, and to F. M. Burnet, M.D., F.R.S., for his distinguished work on bacteriophages, viruses, and immunity, and for his contributions to the study of infectious disease as an ecological phenomenon. The Royal Society has awarded the Copley Medal to Prof. G. H. Hardy, F.R.S.; the Davy Medal to Prof. L. C. Pauling; the Buchanan Medal to Sir Edward Mellanby, K.C.B., M.D., F.R.S., F.R.C.P., Secretary of the Medical Research Council; and the Hughes Medal to Prof. J. F. Joliot.

### Presentation to Sir Alfred Webb-Johnson

A painting of the Council of the Royal College of Surgeons of England for the year 1946-7 was presented to Sir Alfred Webb-Johnson at a dinner given by the Council for that year at the College on Thursday, Nov. 13, in honour of the President and Lady Webb-Johnson. The painting is by Mr. Henry Carr, and the presentation was made by Sir Cecil Wakeley, the senior Vice-President.

### New Medical Journal

The first number of the *Journal of Clinical Pathology* has appeared recently. It is edited by Dr. A. Gordon Signy for the Association of Clinical Pathologists, and published by the British Medical Association. The annual subscription for four numbers is 25s. (in U.S.A. \$6); single numbers are obtainable at 7s. 6d. The policy of the editorial board is declared to be the publication of original articles, reviews, accounts of technical methods, and abstracts that will be useful to the practising clinical pathologist, whose chief concern is to elucidate disease in man.

### Stalingrad Album

A replica of the Stalingrad Album which records messages of greeting from British contributors to the wartime Stalingrad Hospital Fund, organized by the Joint Committee for Soviet Aid, is now on view at the British Museum until Dec. 6. The original of the album is on exhibition at Stalingrad, beside the Sword of Honour presented by His Majesty the King to the City. The albums are outstanding examples of British craftsmanship. The binding, in red Levant leather, was executed by Mr. Frank Vaughan, book-binder to the late King George V, and the crests were painted by the College of Arms.

### Commonwealth Fund of New York

The Commonwealth Fund of New York announces that a number of Fellowships, open to men only, will be offered in 1948. Full details of the Fellowships and copies of the prescribed form of application may be obtained from the secretary to the Committee of Award (Mr. Richard H. Simpson), Commonwealth Fund Fellowships, 35, Portman Square, London, W.1, to whom the completed form must be sent by Feb. 1, 1948.

### Braithwaite Nursing Home

The Government of Nigeria have renamed the European Hospital, Port Harcourt, the Braithwaite Nursing Home in honour of Dr. E. C. Braithwaite, C.B.E. Dr. Braithwaite has served in the Colonial Medical Service in Nigeria and the Cameroons for over 35½ years, and for over 13 years, until retiring in April last, was in charge of the European and African Hospitals at Port Harcourt.

### Leslie Dana Gold Medal

The National Society for the Prevention of Blindness (1790, Broadway, New York 19, New York, U.S.A.) announces that the Leslie Dana Gold Medal for 1947, awarded annually for outstanding achievements in the prevention of blindness and the conservation of vision, was presented to Dr. Frederick H. Verhoeff, of Boston, Mass., on Oct. 16. Dr. Verhoeff is Professor Emeritus of Ophthalmic Research at Harvard Medical School and consulting chief of ophthalmology at Massachusetts Eye and Ear Infirmary.

### Dr. Jessie Macgregor, Prize

The trustees of the Dr. Jessie Macgregor Prize in medical science have announced the award of the prize, value £75, for the present triennial period to Sheila Sherlock, M.D., M.R.C.P., British Postgraduate Medical School, London, W., for her work on the liver, purpura, and malnutrition in the Ruhr.

### Trachoma

The International Organization against Trachoma, founded in 1929, held its last general meeting in London in 1939. The Executive Committee met in Paris on May 17 of this year under the presidency of Dr. MacCallan, and it was decided to hold the next General Assembly of Delegates and Members and the Scientific Meeting in London in 1950. The Organization hopes soon to begin publishing its quarterly journal again, *La Revue Internationale du Trachome*. Articles by members of the I.O.A.T. may be sent to Dr. Jean Sedan, 94, Rue Sylvabelle, Marseille. The annual subscription is 25s. Further information may be obtained from the President, Dr. A. F. MacCallan, Westminster Hospital Medical School, 17, Horseferry Road, London, S.W.1.

### Pharmacy Working Party

A Working Party has been appointed by the Minister of Health and the Secretary of State for Scotland to investigate the differences in the work of pharmacists in England and Wales and in Scotland in dispensing and supplying medicines and appliances, with particular reference to conditions likely to arise under the National Health Service. The Working Party consists of two pharmacists from England and Wales—Messrs. G. H. M. Graham and D. A. Bryan—and two from Scotland—Messrs. A. A. Meldrum and J. Shields—under the chairmanship of Mr. William Penman, M.B.E., a past president of the Institute of Actuaries. The investigation will probably extend from about mid-November to mid-February.

### Harveian Society of London and Prehistoric Society

The late Sir Norman Gray Hill, Bt., M.C., R.A.M.C., who was killed in Sicily on Feb. 24, 1944, has left the residue of his estate to be divided between the Prehistoric Society and the Harveian Society of London.

### Appointment for Distinguished Services

Dr. A. C. Kathigasu, medical practitioner, Ipoh, Malaya, has been appointed M.B.E. (Civil Division) for services to the Forces during military operations in Malaya prior to Sept. 2, 1945.

### Cancer Tests in U.S.A.

A plan consisting of twice-yearly examinations of all women over 40 years old in the State of Delaware has been approved by the Delaware Division of the American Cancer Society. Women who can afford it will pay \$3 for each examination.

### Wills

Dr. Wilfrid Boothby Blandy, of Nottingham, left £129,127. He left £2,000 to be held for up to fifteen years for the establishment of a faculty of medicine at the University College of Nottingham. Dr. Joseph Stanislaus Gubbins, formerly of Ealing and Hounslow, left £20,918. Mr. Philip Roscoe Wrigley, formerly consulting surgeon to the Manchester Royal Infirmary, left £29,785.

## COMING EVENTS

### Social Sciences

A conference to consider action to be taken on the Association of Scientific Workers' Report entitled "The Furtherance of the Social Sciences" will be held on Nov. 22 at 2.30 p.m. at Gas Industry House, 1, Grosvenor Place, London, S.W.1. Prof. V. G. Childe will speak on "The Need for the Greater Use of the Social Sciences." Mr. I. Mikardo, M.P., and Mr. R. Innes will open a discussion on future action to win support for the proposals in the Report.

### Health and Housing

Mrs. Gilbert, of the British Federation of Social Workers, will lecture on "The Health Visitor and Housing" at the Housing Centre, 13, Suffolk Street, Haymarket, London, S.W.1 (Tel. Whitehall 2851) on Nov. 25.

### Society of Chemical Industry

A meeting of the Microbiological Panel of the Food Group of the Society of Chemical Industry will be held at the Chemical Society's rooms, Burlington House, Piccadilly, London, W., on Wednesday, Nov. 26, at 6.15 p.m., when two papers on "Biological Stability of Processed Fish and Manufactured Fish Products" will be presented.

**Institute for the Scientific Treatment of Delinquency.**

The ninth annual general meeting of the Institute for the Scientific Treatment of Delinquency will be held at 8, Bourdon Street, Davies Street, London, W., on Wednesday, Nov. 26, at 6.30 p.m., when the speaker will be the Rt. Hon. Walter Elliot, M.P.

**Society of Medical Officers of Health**

A meeting of the Society of Medical Officers of Health will be held at B.M.A. House, Tavistock Square, London, W.C., on Thursday, Nov. 27, at 5.30 p.m., when Sir Allen Daley will give an address entitled "My American Diary."

**Medico-Legal Society**

A meeting of the Medico-Legal Society will be held at 26, Portland Place, London, W., on Thursday, Nov. 27, at 8.15 p.m., when Dr. W. R. H. Heddy, H.M. Coroner, Eastern District, County of London, will read a paper on "Death on the Roads: an Analysis of 200 Fatal Traffic Cases."

**Medical Society for the Study of Venereal Diseases**

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, Cavendish Square, London, W., on Saturday, Nov. 29, at 2.30 p.m., when a paper on "Some Psychological Aspects of Venereal Disease" will be read by Dr. E. Wittkower.

**SOCIETIES AND LECTURES****ROYAL SOCIETY OF MEDICINE**

**Section of Odontology.**—Monday, Nov. 24, 5.30 p.m. Paper by Miss E. M. Knowles: A Survey of the Dental Condition of Children in Day and Residential Wartime Nurseries.

**Section of Medicine.**—Tuesday, Nov. 25, 8 p.m. Short papers by Sir Allen Daley: Acute Anterior Poliomyelitis; Dr. A. Margaret C. Macpherson: Some Atypical Primary Tuberculous Lesions; Dr. J. E. Capes: The Use of Tubular Blockade in Penicillin Therapy.

**Section of Endocrinology.**—Wednesday, Nov. 26, 5 p.m. Discussion: Simmonds's Disease. Openers: Prof. H. L. Sheehan, and Drs. A. W. Spence, Russell Fraser, and S. L. Simpson.

**Section of Urology.**—Thursday, Nov. 27, 8 p.m. Clinico-pathological Meeting.

**Section of Paediatrics.**—Friday, Nov. 28, 5 p.m. Discussion: The Place of Child Guidance in the New Health Service. Openers: Drs. Ian Skottowe, A. A. E. Newth, and Mildred Creak.

**LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.**—Tuesday, Nov. 25, 5.15 p.m. Dr. Bernard Katz: Propagation of Impulses in Muscle Fibres and the Initiation of Muscle Contraction.

**MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.**—Monday, Nov. 24, 8.30 p.m. Discussion: Tumours of the Bladder. To be introduced by Messrs. E. W. Riches, W. Somerville Mack, and R. W. Reid.

**INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.**—Wednesday, Nov. 26, 3.30 p.m. Dr. Mary D. Sheridan: Hygiene in the Nursery and Playroom (illustrated).

**ROYAL MEDICAL SOCIETY.**—At Balmoral Rooms, Edinburgh, Thursday, Nov. 27, 8 p.m. President's Annual Dinner. At 7, Melbourne Place, Edinburgh, Friday, Nov. 28, 8 p.m. Address by Prof. Ian Aird: The Surgical Management of Peptic Ulcer.

**POSTGRADUATE DIARY**

**EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.**—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, Nov. 25, 5 p.m. Dr. J. L. Henderson: The Child's Inheritance.

**EDINBURGH ROYAL INFIRMARY.**—Thursday, Nov. 27, 4.30 p.m. Honyman Gillespie Lecture by Prof. J. Chassar Moir: November, 1947, and its Sequel.

**INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.**—Tuesday, Nov. 25, 5 p.m. Dr. I. Muende: Pathological Demonstrations.

**INSTITUTE OF LARYNGOLOGY AND OTIOLOGY, 330-2, Gray's Inn Road, London, W.C.**—Monday, Nov. 24, 6 p.m. Cinematograph films. Mr. Geoffrey Bateman: Organic Disorders of the Larynx; Dr. Paul S. Holinger: Bronchial Neoplasms. Wednesday, Nov. 26, 11.30 a.m. Prof. T. Pomfret Kilner: Plastic Surgery.

**LONDON CHEST HOSPITAL, Victoria Park, E.**—Friday, Nov. 28, 5 p.m. Dr. K. Shirley Smith: Acute Heart Failure.

**APPOINTMENTS**

Victor F. Lambert, M.D., Ch.M.Manch., F.R.C.S.Ed., has been appointed Professor of Otolaryngology at Manchester University, where he has been Lecturer in Diseases of the Ear since 1935.

Prof. Michael Polanyi, M.D., F.R.S., has been appointed Professor of Social Studies at Manchester University.

Prof. Polanyi graduated in medicine at Budapest, and was appointed Professor of Physics and Chemistry at Manchester University in 1933.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

**Gideon.**—On Oct. 27, 1947, at Lindo Wing, St. Mary's Hospital, to Peggy a Dr. David Gideon, a daughter.

**Hargrove.**—On Nov. 11, 1947, at Wingfield Nursing Home, Wokingham, Elizabeth (née Corbett-Lowe), wife of Dr. Peter Hargrove, a son.

**Jacobs.**—On Nov. 10, 1947, at St. Mary, Islington, Hospital, London, to Lu (Dr. Frank), wife of Dr. A. L. Jacobs, a son.

**Lowe.**—On Nov. 5, 1947, at Ardeneale Nursing Home, Nunthorpe, Middlesbrough, to Dorothy (née Arnot), wife of Dr. G. S. Lowe, a daughter.

**Mackenzie.**—On Nov. 7, 1947, at Inverness, to Marjorie, wife of Dr. G. Mackenzie, a daughter.

**Southern.**—On Nov. 10, 1947, at Queen Charlotte's Maternity Hospital, Elizabeth (née Raphael), wife of Dr. E. M. Southern, a daughter—Jude Helen.

**DEATHS**

**Bristow.**—On Nov. 10, 1947, at a London Nursing Home, Walter Rowland Bristow, F.R.C.S., aged 64.

**Crowe.**—On Nov. 12, 1947, at 38, Bradford Drive, Ewell, Surrey, 1st Tabuteau Crowe, L.M.S.S.A.

**Dickinson.**—On Nov. 15, 1947, at West House, Chiswick Place, Eastbourne, William Henry Dickinson, M.B., Ch.B.Ed., Lieutenant-Colonel, I.M.S. retired.

**Fraser.**—On Nov. 9, 1947, at Fittleworth, Sussex, Margaret Helen Fraser, M.B., B.S., aged 75.

**Giuseppe.**—On Nov. 10, 1947, at "Treviso," Felixstowe, Paul Léon Giuseppe M.D., F.R.C.S.

**Hendrie.**—On Oct. 27, 1947, at 63, Westwood Road, Tilchurst, Reading, Berks, Helen MacDougall Hendrie, M.D., aged 64.

**Ritchie.**—On Nov. 8, 1947, at 511, George Street, Dunedin, New Zealand, Russell Ian Ritchie, M.B., M.R.C.O.G.

**Scholefield.**—On Nov. 9, 1947, at Hereford, Robert Ernest Scholefield, M.B. B.Ch.

**Shea.**—On Nov. 12, 1947, at St. George's Nursing Home, Royston, Colere Henry Francis Shea, D.S.O., late R.A.M.C., aged 75.

**Unsworth.**—On Nov. 11, 1947, Jonathan Unsworth, L.R.C.P.&S.I., aged 60.

**Waite.**—On Nov. 10, 1947, at 24, Portarlington Road, Bournemouth, Joseph Edward Waite, M.B.

**Winder.**—On Nov. 12, 1947, James Herbert Roche Winder, D.S.O., MD Lieutenant-Colonel, late R.A.M.C.

**EPIDEMIOLOGICAL NOTES****Dysentery at Wallingford**

This explosive outbreak occurred in a mental hospital in the Wallingford Rural District, and by Oct. 31 there had been 362 cases notified. A few secondary cases are still occurring. The total population of the hospital is about 1,400. Between Sept. 22 and Oct. 21 13 cases of acute gastro-enteritis appeared in the same male ward. On Oct. 21 the Public Health Laboratory at Oxford isolated *Shigella flexner* type 103 from rectal swabs from 3 of the 13 cases. This ward contained the worst mental cases in the hospital.

There followed 35 fresh cases on Oct. 21, 71 on Oct. 22, 57 on Oct. 23, and then on successive days: 42, 47, 24, 20, 22, 20, 6, and 4 on Oct. 31. On Oct. 21 the fresh cases were isolated so far as possible, and methods of disinfection of excreta and soiled bedding, etc., and of preparing and cooking food were investigated. None of the staff or patients who worked in the kitchen had been ill recently, but rectal swabs were taken. Rectal swabs were taken from those of the original 13 who were about again, from the 35 fresh cases, and also from the one patient in hospital who had a previous history of dysentery (type unknown).

It was thought that this "explosion" might be due to a superimposed epidemic of salmonella or staphylococcal food poisoning, but the laboratory failed to find pathogens in samples of food and isolated *Shigella flexner* of the same serological type in swabs from the fresh cases. By Oct. 24 it seemed probable that there was a carrier at work in the kitchen, and therefore the taking of diagnostic swabs was discontinued and all efforts were concentrated on those who prepared food. On Oct. 28 the organism was isolated from two patients working in the kitchen. One of them subsequently developed the disease, but the other remained symptomless throughout. Their removal from the kitchen caused a marked drop in the fresh case rate.

There were only 4 cases in the surrounding district, but each worked in the hospital and had at least one meal a day there. Water, milk, and sewage effluent showed no pathogens. All the cases were treated by sulphonamides, but details of the numbers who have had sulphonamides prophylactically and who have subsequently developed the disease or have become symptomless excretors are not yet available.

The one patient who had a history of dysentery has had two negative swabs, but on Oct. 27 produced a positive swab, and on Nov. 4. As he has been swabbed several times since the dysentery and the result has been negative each time, his case would appear to have been a reinfection rather than the source of the outbreak. The source then is unknown, but the explosive outbreak was probably due to one or both of the patients in the kitchen, who were possibly infected by one of the original 3 cases. There have been no deaths. Investigations are still continuing.

### Poliomyelitis and Polio-encephalitis

In the week ended Nov. 8 the decline in the notifications of poliomyelitis 198 (221) and of polio-encephalitis 12 (22) continued. Figures for the previous week are shown in parentheses. The small decline this week gives some support to the opinion expressed last week (Nov. 15, p. 801) that the incidence is likely to remain relatively high for some time. The rate of decline has been fairly consistent for the last three weeks. If it remains the same for the rest of the year then there may still be about 100 notifications a week at the end of December.

### Cholera in Egypt

The decline in the incidence of cholera in Egypt still continues. According to the Egyptian Ministry of Health only 88 of Egypt's 4,000 villages are affected. On Nov. 17, for example, there were only 34 deaths and 55 new cases reported. In the week ending Nov. 11 there were 1,895 cases and 1,049 deaths, which should be compared with the peak figures of 4,566 cases and 2,075 deaths in the third week of October.

A careful watch is being kept in this country on passengers arriving by air from Egypt. So far the question of cholera has been raised in only one case. This was a man of 40, flying home from Australia, who on Nov. 10 spent one night in a Cairo hotel. He reached this country by flying boat on Nov. 12 and two days later had all the symptoms of a severe cold. On Nov. 15 he complained of diarrhoea and abdominal pain, and he passed some blood and mucus. Dr. R. Swyer, of the North Eastern Hospital, Tottenham, N.15, informs us that clinically the diagnosis appears to be that of a mild dysentery rather than cholera, but the laboratory investigations are not yet complete.

### Discussion of Table

In England and Wales the rising trend in the incidence of scarlet fever and measles was continued with increases of 77 and 71. Increases were also recorded in the notifications of whooping-cough 34, acute pneumonia 20, and paratyphoid fever 12. There were decreases in the notifications of dysentery 214, acute poliomyelitis 30, and diphtheria 60.

The rise in the notifications of scarlet fever was due to the northern section of the country; in the South the incidence declined. The only variation of any size in the returns of measles was an increase of 50 in Durham.

The largest rises in the incidence of whooping-cough were those of Yorkshire West Riding 55 and Lancashire 31. A decrease in the incidence of diphtheria was general and the largest falls were Middlesex 11 and Lancashire 11. Of the 15 cases of paratyphoid fever 8 were notified in Leicester C.B. A further 55 cases of dysentery were reported from the outbreak in Berkshire, Wallingford R.D., where 260 were notified in the preceding week.

The general decline in poliomyelitis continued; the largest returns during the week were Lancashire 35, London 20, Yorkshire West Riding 17, Middlesex 12, and Lincolnshire 10.

In Scotland there were increases in the notifications of measles 26 and diphtheria 14, while decreases were recorded for scarlet fever 22, acute primary pneumonia 23, whooping-cough 13, and dysentery 10. The largest local rise in the incidence of diphtheria was 9 in Glasgow. Only 2 cases of dysentery were notified in Edinburgh compared with 13 in the preceding week.

In Eire infectious diseases were less prevalent than in the preceding week; the only exception was a rise of 15 in the notifications of whooping-cough. The notifications of diarrhoea and enteritis fell by 31. In contrast to the returns for the whole country a small increase was recorded in Dublin C.B. in the incidence of scarlet fever and measles.

In Northern Ireland a decrease of 10 was recorded in the notifications of scarlet fever.

### Week Ending November 8

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,730, whooping-cough 772, diphtheria 219, measles, 2,179, acute pneumonia 571, cerebrospinal fever 39, acute poliomyelitis 198, acute poliomyelitis 12, dysentery 105, paratyphoid 6, and typhoid 9.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales\* (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Prophylaxis of the Common Cold

**Q.**—For some years I have used intranasal drops of the following formula with some success in the prophylaxis of colds: Ephedrine, 0.5%; eucalyptol, 0.5%; camphor, 0.5%; castor oil, 0.5%; liquid paraffin, q.s. 100%. Is any harm likely to result from this practice?

**A.**—The formula given is similar to that of the compound ephedrine spray of the *British Pharmaceutical Codex*, except that the *B.P.C.* formula contains 1% ephedrine. This preparation is presumably more effective as a spray than as drops. For those who dislike oily sprays, a solution containing 1% ephedrine hydrochloride and 4% dextrose in normal saline may be used as a spray. It is probable that too prolonged use of such a preparation in the form of drops will injure the mucous membrane. According to R. E. Ryan (*Proc. Mayo Clin.*, March 19, 1947) the excessive use of nose-drops over a prolonged period has been observed to cause a clinical syndrome in human beings, which may be designated "vasomotor rhinitis medicamentosa." The effects were produced in rabbits which had nasal drops instilled four times daily over a period of ten weeks. Sections of the mucosa showed degeneration, then oedema, and finally metaplasia of the epithelium into the stratified squamous-cell type.

### Concentrated Vitamins

**Q.**—It is said that certain vitamins are incompatible and should not be taken together in concentrated form, as in the various composite vitamin tablets now widely sold. Is there any truth in this?

**A.**—There would appear to be some confusion between the "concentrated form" of vitamins in certain medicinal products and exceptionally large doses of vitamins. While the latter are hardly practicable without the former, it is possible, and very widely customary, to take highly concentrated preparations of some vitamins at physiological levels. There is much scattered evidence to suggest that under certain experimental conditions large doses of one vitamin may affect the metabolism of others at more normal levels, but there does not seem to be any clear evidence at all for antagonistic action between vitamins fed at therapeutic levels or even considerably above this—that is, in the quantities practicable with many vitamin tablets and capsules on the market in this country and elsewhere. It must not be forgotten, however, that feeding one vitamin or a limited number of vitamins to a patient suffering from multiple vitamin deficiency may result in the flaring-up of symptoms due to the absence of an essential nutrient not being replaced by the therapeutic measure. Thus symptoms of beriberi have been evoked by administering therapeutic doses of nicotinic acid and riboflavin to pellagrins. The position of such patients, correctly described as suffering from deficiency disease, is doubtless very different from that of "normal" subjects taking multivitamin preparations as supplements to their ordinary food intake of nutrients.

### Flying for Whooping-cough

**Q.**—A patient wishes to try the effect of an aeroplane flight on his child who is suffering from whooping-cough. Is there any standard of (a) rate of climb, (b) height attained, and (c) rate of descent? What is the accepted explanation of the beneficial effects supposed to result from this treatment?

**A.**—There is no standardized procedure for the treatment of whooping-cough by altitude. There has as yet been no conclusive evidence of its consistent efficacy, except in producing temporary alleviation of symptoms, in tests carried out in this country. A lowering of pressure can more conveniently be produced on the ground in a decompression chamber than in

actual flight; a chamber is being used in Paris on a number of cases at present. Cases tested by the R.A.F. during the war were given a rate of climb and descent of 500 feet (152 m) per minute and kept for one to two hours at 10,000 or 12,000 feet (3,050–3,650 m.) equivalent altitude. The temporary relief at low pressure appears to be due to the lowered friction in the respiratory passages of air at reduced density. No satisfactory theoretical basis has yet been put forward to account for any permanent improvement which may result.

### Treatment of Mongolism

**Q.**—Is there any new treatment for mongolism? I hear recently of the successful use of some endocrine therapy. Will such treatment benefit a mongol aged 18 months, or is it likely to do harm?

**A.**—There is no evidence that mongolism is due to endocrine disturbance, and therefore no endocrine preparation can be justifiably used in treatment of the condition. It should be remembered that all but the lowest grades of mongols will show considerable mental development in the early years of life, and that any "treatment" given is likely to be "successful" in the sense that, after a varying delay, such functions as speech and walking are achieved. In the much over-weight, constipated mongol the use of thyroid extract in a non-specific fashion may produce some physical benefit.

### Taste in the Mouth with Dentures

**Q.**—Since first wearing dentures fifteen months ago a man aged 54 years has had a persistent sweet taste in his mouth, a dirty brown tongue, at times excessive salivation, and at others a dry condition which is sometimes relieved by removing one or other denture. He has had his sinuses, salivary ducts, alimentary tract, and kidneys x-rayed, and his blood tested for sugar and urea; all were normal. He has had two plastic sets, one vulcanite, and one stainless-steel set. I would not care to label him neurotic, but I would like to help him. Can you advise?

**A.**—Tastes in the mouth following insertion of dentures are sometimes due to imperfectly vulcanized or processed vulcanite or acrylic resin dentures. The patient in question has tried several sets of dentures, and it would therefore appear that the base has nothing to do with the condition in his particular case. Some patients do not tolerate dentures of any sort well, and any foreign body in the mouth may stimulate an excessive flow of saliva. Scrupulous cleanliness of the dentures, washing them after meals, etc., may be helpful; but if, as is probable, this has already been tried with no result, the patient must either undergo the inconvenience of the symptoms of which he complains or do without dentures.

### Ennuechoidism

**Q.**—Eight years ago a patient, now aged 25, had testes the size of a pea, with a feminine voice and bodily contours. There were no secondary sex characters, his penis measured 2½ in. (6.5 cm.) and pubic hair was scanty. He was 4 ft. 11 in. (150 cm.) tall. A course of chorionic gonadotrophin was started at that time, but without obvious result. During 1940, following a course of testosterone propionate, the penis became bigger and the patient had marked erections and some ejaculation. In 1942 he again had a course of testosterone propionate, with good results. He was given three further courses in 1943, after which he achieved successful intercourse. Continued treatment with testosterone resulted in an increase in size of the penis, almost to normal, moderate increase in size of the testes, a deeper voice, and better bodily development. His height is now 5 ft. 1½ in. (156 cm.). With cessation of treatment libido is disappearing and the patient is losing his self-confidence. Can you suggest further treatment?

**A.**—The diagnosis in this case appears to be ennuechoidism—that is, a primary gonadal defect. This is based on the fact that the patient did not respond to gonadotrophic hormone, as he would have done with a primary pituitary defect, but he did respond to testosterone propionate, which increases the size of the penis but not of the gonads and, further, restores the produces potency without, however, fertility. On the other hand, his subnormal height would, be more compatible with a primary pituitary defect. The increase in height during the

ient shows that the epiphyses are ununited, even at the age of 5, and this occurs with hypogonadism which is either primary or secondary. It also illustrates, contrary to general belief, that testosterone in therapeutic doses does not cause the epiphyses to unite, although in small animals, experimentally, it may do so, and premature union of the epiphyses occurs in sexual precocity. The treatment is substitution therapy, and therefore relapse follows cessation of therapy. The writer has found that insertion of testosterone propionate tablets, at intervals of eight months, is the best treatment, and the usual dose is eight tablets of 100 mg. each. He has also found the best site to be in the subcutaneous fat of the lower abdomen. The technique consists in local procaine analgesia, an incision of 1 to 1.5 cm. down to and through the subcutaneous fat, and the insertion of sinus forceps to make a pocket. The tablets can be implanted either directly with ordinary forceps or preferably through a blunt trocar and cannula. Two pockets in the subcutaneous fat in different downward directions can be made through the same primary incision. One suture is sufficient. An alternative method of treatment is one or two 5-mg. tablets of methyl testosterone by mouth, or allowed to dissolve under the tongue, three times daily.

### Estimation of Serum Phosphatase

**Q.**—In what conditions is estimation of the serum phosphatase of value? What is the difference between acid and alkaline phosphatase, and what are regarded as the normal ranges of each in adult life and childhood? What are Kay units, King-and-Armstrong units, and Bodansky units?

**A.**—Phosphatases are classified according to their origin or the pH at which they show maximum activity. Alkaline phosphatase, derived from osteoblastic and osteoclastic cells, has maximum activity between pH 9 and 10; while acid phosphatase from prostatic epithelium has maximum activity at about pH 4.8. Serum levels run parallel with the quantity of phosphatase-secreting tissue in the body. Serum alkaline phosphatase is therefore at a minimum in the normal healthy adult, and increases whenever bone is being formed or rapidly destroyed. The most important of such conditions are: normal osteogenesis in infancy, childhood, and adolescence; osteomalacia and rickets (including those forms caused by chronic azotemia or chronic steatorrhea), hyperparathyroidism, osteitis deformans, and the osteoblastic (as opposed to osteolytic) forms of osteogenic sarcoma. Small and inconstant increases occur also in multiple myeloma, carcinomatosis of bone, and during the healing of fractures. Serum alkaline phosphatase is also increased in obstructive jaundice, and irregularly and to a less extent in other types of jaundice; a level of over 30 King-and-Armstrong units in a jaundiced patient is pathognomonic of obstruction.

Serum acid phosphatase from prostatic mucosa is low in all normal subjects, being increased only when skeletal metastases of a primary carcinoma of the prostate have developed. Treatment with oestrogens, causing fibrosis of the metastases, leads to a reduction in serum acid phosphatase, so that serial estimations of the latter are used to control the treatment. The serum prostatic phosphatase is inactivated by incubation at 37° C. for one hour, or by addition of 25% ethyl alcohol; thus a very precise estimation can be made. Neither phosphatase has been prepared pure, so that their concentration is measured in arbitrary units, which depend on (1) incubation time, (2) nature of substrate, (3) nature of buffer, (4) pH of incubation, (5) volume of serum to which unit is calculated, and (6) temperature (always 38° C.). The usual methods of estimation are:

Method	Incubation Time	Buffer	pH	Volume of Serum	Nature of Unit	Normal Range	
						Adults	Children
Substrate Sodium Glycerophosphate							
Kay .. .. .	48 hrs.	None	7.6	1 ml.	1 mg. P liberated	mg.	mg.
Jensen and Kay .. .. .	3 hrs.	Glycine NaOH	8.6	100		0.03-0.21	0.17-0.33
Bodansky .. .. .	1 hr.	Veronal	8.6	100		3-8	6-20
Substrate Disodium Phenyl Phosphate							
King and Armstrong .. .. .	30 mins.	Veronal	9.0	100	1 mg. phenol liberated	3-14	10-30
King .. .. .	15 mins.	Na <sub>2</sub> CO <sub>3</sub> -NaHCO <sub>3</sub>	10.0	100		3-14	10-30
King, acid phosphatase .. .. .	60 mins.	Sodium citrate-HCl	4.8	100		1-3	

### Infected Burn

**Q.**—A woman spilled pure carbolic acid over her forearm and developed a superficial burn which became infected with *Pseudomonas pyocyanea*. As one area heals another becomes inflamed and breaks down; after daily dressings for eight months the condition remains unchanged. What treatment do you advise?

**A.**—Presuming that no question of artefact arises in this case, it is suggested that some form of skin graft is most likely to lead to complete healing. A 1% acetic acid dressing will usually do much to clear up a superficial pyocyanea infection, when, after forty-eight hours' saline dressings, small patch grafts could be applied to the raw areas, dusted with penicillin powder, and fixed firmly by an occlusive pressure dressing for eight to ten days. If the whole area of skin on the back of the forearm is atrophic, some more radical form of plastic repair may in the end be the quickest solution of the problem—for example, a "flap" full-thickness graft from the anterior abdominal wall.

### Terminology in Smallpox Vaccination

**Q.**—Recently I saw a vaccination record card which stated that in cases of revaccination the result after forty-eight hours should be described as a "reaction of immunity," or an "accelerated reaction (vaccinoid)," or a "typical primary vaccinia." It was stressed that a report of "No reaction" would not be accepted. In the old days we used to describe the results as successful or unsuccessful. What is the "reaction of immunity"; and what is an "accelerated reaction"?

**A.**—The form referred to, which appears to be similarly worded to that recommended by Unrra, uses terms which have been the subject of recent discussion. The term "reaction of immunity" has been applied to a local reaction reaching a maximum size on the second or third day and accompanied by elevation and itchiness of the site but without a vesicle. In many quarters this is considered to be unwarranted, because it may be due to weak lymph or even to sensitivity to protein or other substance in the lymph and not the living virus of vaccinia. This is the view taken by the Ministry of Health (see *Mon. Bull. Min. Hlth.*, 1947, 6, 164). An "accelerated" (or vaccinoid) reaction is when the local reaction reaches a maximum size between three and seven days after inoculation and there is some degree of vesicle formation. This occurs in an individual who has a partial degree of immunity as a result of a previous vaccination.

### Erythema Induratum

**Q.**—In a case of erythema induratum scrofulosorum is there any effective treatment to clear or prevent the unsightly nodules on the legs?

**A.**—The affection is a gummatous tuberculide. Overhaul of the patient or contacts sometimes reveals the source of infection, treatment of which is helpful. Rest and supporting bandages or stockings—warmth and support—are important. Injections of neoarsphenamine, 0.45 g. weekly for six injections, or gold or tuberculin often control the infection for long periods.

### Rectal Prolapse

**Q.**—What is the best treatment for rectal prolapse? Is an operation likely to effect a cure, and, if so, what is the operation of choice?

**A.**—Rectal prolapse is essentially of two types—partial (or mucosal) and complete; in the latter the entire rectal wall is everted and extruded. The former is more frequently a

unilateral condition and rarely exceeds 2 in. (5 cm.) in length. The anal orifice remains central and circular. In procidentia (or complete prolapse) the protrusion may be 6 in. (15 cm.) or more, the anal orifice is frequently eccentric and slit-like, and a finger in the rectum will recognize the thickness due to the presence of the muscular coats. In either case in an adult, particularly if the condition is of long standing, operation offers the best solution. Mucosal prolapse is treated either by excision of the excess tissue, or preferably by ligature—in sections, in a manner similar to that used in treating internal haemorrhoids. In procidentia, amputation of the extruded portion (Miles's operation) is preferable to the many varieties of suspension or fixation. It need hardly be stressed that, before treating the prolapse as such, all possible underlying causes should be excluded.

## NOTES AND COMMENTS

**Sterilization of Syringes and Specula.**—Messrs. JOHN FOSTER and C. H. LE MAY (Leeds) write: It is probable that no instrument is more frequently used in medicine and surgery than the hypodermic needle and glass syringe in their various forms. From time to time tragedies are recorded from poor sterilization, and queries appear in the *Journal* as to the best method of rendering the instrument sterile. In "Any Questions?" (Oct. 25, p. 680) a correspondent who had difficulties with liquor sterilizans and a phenoloid asks whether it is "possible to sterilize a spinal needle satisfactorily without an autoclave." Your reply recommends hot-air sterilization and boiling (presumably in water). If we can accept experiments on hypodermic syringes and needles as bearing on the question and if by satisfactory sterilization the instruments are to be rendered spore-free and left undamaged by the process, we would suggest that until new alloys and glasses are invented, the answer should really be, "No."

**Hot Air.**—Hanne<sup>3</sup> using *B. mesentericus* in 17 hot-air sterilizers found that practically no spores were killed by this method, and that 50 out of 99 needles routinely sterilized by hot air in Berlin hospitals were non-sterile.

**Boiling in Water.**—While vegetative forms are rapidly killed by boiling in water, it is sometimes overlooked that killing spores by this method is a slow process. Boiling in water also rusts needles and gradually dissolves the glass of the syringe. Experiments in which all-glass syringes were boiled for 70 hours showed losses of weight of the order of 0.14%.

**Boiling in Alkali.**—Garrod claims that five minutes' boiling in 2%  $\text{Na}_2\text{CO}_3$  kills all spores.<sup>2</sup> This is a considerable speed-up on water-boiling, but unfortunately this (1) leaves a trace of alkali in the syringe barrel. We cannot say if this would contaminate aspirated fluid seriously, but it might upset certain local analgesics soluble only in acid solution. Harvey, Le May, and Shuttleworth, using the "A.C.10 (surgical)" method (essentially a sterilization by boiling  $\text{Na}_2\text{CO}_3$ ), found the alkali effect negligible on "cobefrin," the initial pH of 2.8–3.6 being altered only to 4.6–5.2, which is regarded in dental practice anyhow as advantageous (at least two of the manufacturers of local analgesic solutions for dental use, as prepared are at low pH, issue "alkalinizing" preparations for use with them prior to injection). (2) Dissolves the glass (0.57% loss after 70 hours in an all-glass syringe), leading ultimately to a leaky piston. (3) Reduces but does not prevent rusting of the needle, which becomes obstructed at a rate which varies with the metal.

**Boiling in Alkali and A.C.10.**—This method<sup>4</sup> is applicable to syringes and protects the needles. Unfortunately the glass is attacked to the same extent as with 2%  $\text{Na}_2\text{CO}_3$ , and a certain amount of oily A.C.10 remains in the barrel and is difficult to remove. The A.C.10 has, however, been shown<sup>4</sup> to be biologically inert and non-irritant. Harvey,<sup>4</sup> however, has found it effective for dental work, though one of us reserves it for sharp-edged ophthalmic instruments, and uses boiling in sodium carbonate alone for syringes. It is true the damage to the syringe is slow, but we are now entering on a period of shortage when such minutiae may be of importance.

**Lead Contamination of Water.**—ALAN W. STEWART, D.Sc., F.R.I.C. (London, W.C.), writes: With reference to the question of lead contamination of water (Nov. 8, p. 758) I think the answer is, "No." The amount of lead stated by the questioner is 0.04 part per million. In the U.S.A. 0.1 part per million is accepted. It is probable that 0.5 part per million is safe for domestic use. Others

consider this amount too high if the risk of lead poisoning is to be avoided. In the annual report of the Chief Medical Officer of Ministry of Health, 1934, it is stated that 0.2 part per million may be tolerated, and this would probably be passed as safe. A water containing 1 part per million has hitherto been considered dangerous provided it is certain that this amount is never exceeded. Other authorities tolerate 1/100 grain per gallon (0.143 part per million). From your reply it would take 50 litres of water to be consumed daily to reach the 2 mg. of the strength of lead 0.04 per litre.

**"Jugged Hair."**—Prof. T. POMÉRET KILNER (Oxford) writes: The cover of the *British Medical Journal* of July 27, 1946, appears in large print "Vinesthene Anaesthesia for Repair of Hair-lip: Cleft Palate." I expected to see some apology for this mis-spelling or at least a letter from some wag cleverly pulling the leg of Editor who had allowed it to pass him. Either it went unnoticed or I overlooked reference to it in subsequent issues of the *Journal*. In the *Lancet* of Oct. 18 (p. 588) in an annotation I read, "the feeding of a child with a double hair-lip is at best tedious... In the three issues since that date I have seen no correction this mis-spelling. It is perhaps to be expected that a surgeon who receives a great many letters about this condition from parents, general practitioners should have come across this mistake frequently, but it seems odd that the editors of our two leading medical journals should have allowed it to pass. For twenty years or more I have refused to use the term at all, and I and those who have worked with me have adopted the terminology "cleft lip," as suggested, I believe, by Ritchie, of St. Paul, Minnesota—misdescriptive, less inapt, and less likely to lead to incorrect spelling.

\* [Prof. Kilner is right. We must have been thinking of split hairs.—Ed., B.M.J.]

**Examination of Saliva.**—Mr. G. E. P. PHILPOTS, D.D.S. (M Bourn; Victoria), writes: With reference to the question and answer (Aug. 23, p. 318) under this heading, as several medical friends have asked me to make comments, it was thought the following remarks might be of interest to your readers. The taking of plenty of milk and a "sufficient" dosage of calcium and vitamin D for the ten years prior to the time of being reported would not prevent dental caries developing if the ill effects of an unbalanced diet over period from early childhood have existed. The proposed test of the saliva for acidity would be of value if it showed an amphoteric reaction to litmus paper. I recall that my friend and teacher, the late Dr. E. C. Kirk, when dean of the Dental School of the University of Pennsylvania, was a physiological chemist and keen student of salivary analysis. In cases similar to that reported above I always (generally) found the (mixed) saliva would give an amphoteric reaction due to the presence of acid sodium phosphate. This reaction indicated a susceptibility to dental caries caused by excessive consumption of refined sugars and starches, which in turn causes an excess of hypothetical  $\text{H}_2\text{CO}_3$ . There follows a chemical reaction with the acid sodium phosphate in the saliva, represented by the following equation:

Normal saliva is a supersaturated solution of calcium phosphate. When there is an excess of acid sodium phosphate present, such excess is due to the eating of an excess of refined starches and sugars and aggravated by lack of vitamin D. The type of patient mentioned does not respond to diet treatment, but, strange to relate when the age of about 25 years is reached there seems to be a period of immunity to dental caries, which, however, sets in again a few years later. The excessive consumption of starches and sugars can in many mouths produce a saliva which erodes the enamel thus allowing the free entry of various decalcifying bacteria always present in the oral cavity to do their work of destruction.

**"Cancer Research Society."**—A deceased client of Messrs Farrington and Winterton, solicitors, has bequeathed a one-third share in her residuary estate to the "Cancer Research Society." Inquiries have failed to discover whether this society exists. Messrs Farrington and Winterton would be glad to receive any information at 12A, Marlborough Place, Brighton, 1.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 22 1947

## HEARD AT HEADQUARTERS

### Local Executive Councils

We are pleased to learn that Dr. E. A. Gregg, Deputy Chairman of the Representative Body, has been appointed to the co-chairmanship of the Executive Council for London. No happier choice could have been made. Dr. Gregg's long chairmanship of the London Panel Committee and now of the Insurance Acts Committee has revealed him a master of committee procedure and possessed of an intimate personal knowledge of the demands and exigencies of a public service. He is himself a busy general practitioner in central London. Dr. P. V. Anderson, of Shildon, Co. Durham, has been appointed vice-chairman of the Durham County Executive Council. Dr. Anderson is also a member of the Insurance Acts Committee, and is chairman of the Durham County Panel Committee and vice-chairman of the Finance Committee of the Durham County Insurance Committee.

Members of the medical profession number at the minimum seven out of the twenty-five members of an Executive Council, and it should often be possible by arrangement with other groups to arrange for a medical vice-chairman. The chairman, who is the Minister's nominee, will in most instances be lay.

### And Local Medical Committees

From correspondence received at Headquarters it is evident that there is some misapprehension about Local Medical Committees. Attention has been drawn to the fact that the Minister of Health has recognized the existing Local Medical Committees which have functioned under the National Health Insurance scheme as being the proper bodies to act under that name in anticipation of the new Service, and yet there have been no elections of Local Medical Committees in most areas since the service took shape. The Minister has recognized the present Local Medical Committees for the purpose of making the appointments of seven members to the Executive Councils, and he has urged local health authorities to consult these same Local Medical Committees in exercising their powers of co-optation to statutory Health Committees. But such recognition is only an interim measure, and for the purposes of Section 32 of the Act there will be an election of new Local Medical Committees which will be representative of the whole profession, and these will replace the existing bodies. The method of appointment of these committees has yet to be determined.

### Deaf Aids

Not much has been heard about the aids for the deaf which have been promised as part of the National Health Service. The Association has been making some inquiries of the Ministry of Health and the Medical Research Council, particularly about the arrangements which will be made for the prescriptions of the aid to patients and its adjustment to individual cases. An assurance has been received that the supply of the aid will be made at ear-nose-and-throat departments of hospitals and clinics, and that the aid will therefore be adjusted by the otologist at the time of distribution.

### Processing the Patient

In one American medical journal, which is undertaking a study of group practice, an account of how one successful medical group deals slickly with its patients may be read. This

group, housed in a modern three-story building, deals with 250 patients a day. The patient, let us say, has an appointment to see one of the group's seventeen specialists at 10 a.m. At 9.55 he strides through the main entrance and is greeted in a pleasant foyer by a receptionist who checks his name and on the telautograph writes "Mr. A to see Dr. B." This message is flashed to two other departments—one that of the telephone operator, who passes it on to Dr. B's nurse, and the other the business office, where the record librarian takes from her files the case history and drops the envelope through the chute to the receptionist's station. The receptionist, having in the meantime taken certain details, hands the patient to an usher who conducts him to the internal medicine reception-room. The group makes it a practice to "route" all new patients to internal medicine even if their superficial symptoms suggest some other department, for the "internists" are regarded as the family doctors. Dr. B receives the patient in a large consulting-room flanked by two examination-rooms, each with a small dressing-room attached. When the examination or treatment is completed the doctor writes (1) his prescription and (2) his fee slip. The former is dealt with at the group's own pharmacy in the building, and the fee slip with the history envelope goes down to the business office, through which the patient passes on his way out. Here he meets the manager, who gently extracts further information on income and size of family, and may suggest the prepayment plan. If the patient wants to pay cash, a receipt—in triplicate—is made out on a commercial register. Meanwhile Dr. B up above is dictating his comments on the case into a dictaphone.

### Clipped Talk

A distinguished member of the medical profession, himself one of our few remaining orators, deplored to us the other day the slipshod speech so current at medical meetings. A generation ago a large number of those who took part in discussions in medical societies took pains over the style as well as the substance of their utterance, but to-day everything is casual, conversational, and unpolished. It seems to be considered bad form to pay attention to phrasing. On the very day on which this remark was made, one participant at another meeting had mentioned in the course of three minutes "sulphs," "staphs," "streps," and "labs." Why he continued to give "penicillin" its four syllables is not known: but perhaps he reflected that "peni" (pronounced "penny") would not do.

## DISABILITY PENSIONS

*The Ministry of Pensions has issued the following statement on the method by which disability pensions are assessed.*

### Assessment of War Disablement

The basis of assessment of disablement incurred as a result of service in the 1939 world war is laid down in Article 9 of the Royal Warrant, and the degree of disablement due to war service of a member of the Forces is assessed by making a comparison between his condition, as so disabled, and that of a normal healthy person of the same age and sex. In making this comparison no regard is paid to the member's capacity, or failure of capacity, to follow his own or any other specific trade or occupation.

The assessment is based on the *average* degree of disablement over a substantial period—e.g., twelve months—and account is taken of probable variations. Where a man receives a special course of medical or surgical treatment for his pensioned

disablement and as a result is unable to provide by his normal earnings for his own support or that of his family, treatment allowances equivalent to pension for the highest degree of disablement are normally paid in lieu of the current pension.

The degrees of disablement for pension purposes are assessed in multiples of 10 from 20 to 100% (100% representing total disablement). Where the disablement is less than 20%, compensation takes the form of a fixed sum, according to a prescribed scale, and payable by weekly instalments or in a lump sum, or by a combination of both.

The assessments for certain specified injuries, such as the loss of a limb, are prescribed in the Royal Warrant by schedule. Those for other injuries and for diseases are determined by medical boards, which normally consist of two doctors, with specialist advice as required.

#### Ministry of Pensions Responsibilities

The Ministry of Pensions is responsible for the provision of treatment for conditions accepted as attributable to, or aggravated by, war service, unless the required treatment is provided by other authorities—e.g., panel-doctor treatment under the National Health Insurance Acts, and treatment for tuberculosis and mental disease.

Subject to these exceptions the following types of case should be referred by doctors to the regional office of the Ministry of Pensions:

**Ex-Service Cases.**—(a) Where the treatment is required for a disability accepted by the Ministry as attributable to, or aggravated by, war service; this applies also to ex-members of the Polish Resettlement Corps. (b) Where the treatment is required for a condition *prima facie* connected with war service.

**Merchant Navy Cases.**—Where the disability has been accepted by the Ministry as due to a war injury or war-risk injury.

**Civilians and Former Civil Defence Volunteers.**—Where the disability has been accepted by the Ministry as due to a war injury or war-service injury.

The pension order books and leaflets issued by the Ministry to disabled pensioners contain instructions on how to apply to the local chief regional officer of the Ministry when special treatment, or artificial limbs, surgical boots, or other appliances are required. If hospital treatment is urgently necessary and contact cannot be made with the Ministry, the patient's doctor should arrange the necessary admission and inform the Ministry as soon as practicable.

## Correspondence

### Buying and Selling of Practices

SIR,—I wish to thank Dr. A. E. Moore for the courtesy of his reply (Oct. 25, p. 97) to my query (Oct. 11, p. 89). In essence his standpoint is that if we own our practices we shall not be governed by politicians. I should be delighted with this solution. My view is that whether we own our practices or not, and no matter what form the Health Scheme ultimately takes as long as it covers the whole population, we must be under the control of the Government of the day, since practically our whole income will be provided by the Government out of public money. Now this is the crux of the whole question of whether or not buying and selling of practices should continue under a national scheme. No doubt the report of the Negotiating Committee will clarify the picture, including the alleged attractiveness of the Government's proposals for compensation.—I am, etc.,

Southport, Lancs.

S. H. STEWART.

SIR,—I have read with great interest Dr. A. E. Moore's letter (Oct. 25, p. 97) and entirely agree with him. The question of the sale and purchase of our practices is most fundamental and must be considered very carefully. Why Mr. Bevan becomes so emotional on the subject and accuses us of buying and selling

our patients is beyond me, particularly when one reads weekly almost of professional footballers being frankly and unequivocally bought and sold for vast sums. One can hardly expect him to be reasonable, but at least he should be logical.—I am, etc.,

Coventry.

JOHN HALE POWER.

### The Future of the Profession

SIR,—The leading article entitled "Discussion with the Minister" (Oct. 25, p. 661) will do much to allay the fear of members that they were to be presented by a *fait accompli*. There is one jarring note: "The profession will decide its own fate when it is in full possession of the facts." It is to be hoped that this is merely a slip of the pen and not prescience on the part of the writer. The *Oxford Dictionary* gives: "Fate: n. power predetermining events from eternity; what is destined; appointed lot or ultimate condition; death, destruction."

No, Sir. The profession must decide its own future when it is in full possession of the facts. Otherwise what is destined for the profession is destruction of its tenets, death of its principles, and its ultimate condition (or appointed lot) to be overridden by a power predetermining events till eternity.—I am, etc.,

Wokingham, Berks.

J. M. SMILES.

### National Health Service

SIR,—In his letter under the above heading (Nov. 1, p. 100) Dr. H. Firman displays a lack of appreciation of the facts in relation to the motion on hours of duty in the N.H.S. in the A.R.M. of July last. I do not think that he will deny that the profession as a whole by an overwhelming majority has rejected the conception of a whole-time salaried service. Under such a service it would be entirely natural and logical to work definite fixed hours and be freed from all responsibility during periods of off-duty. The G.P. would be provided with consulting premises, in most cases in a health centre, with equipment and clerical and nursing staff. In such a service a doctor naturally would not be expected to assume continuous responsibility for or to a patient, and the instruments which he used would never be his own. The clerical and nursing staff would not be his employees but would, like himself, be State servants.

The profession rejected this conception and has asked for a contract system under which each G.P. shall be responsible for such patients as choose him as their doctor and whom he accepts, at a fixed annual capitation rate. He must provide his premises, his clerical help, and his instruments out of his aggregate fees. If and when health centres are available he may elect to pay for accommodation in one of these.

If Dr. Firman and the other correspondents who demand fixed hours and clerical and nursing aid provided by the Service want a salaried whole-time service let them say so frankly. At any rate they will have to learn that they can't have it both ways. If they want the greater freedom of a capitation system they must submit to the burden, or accept the honour of continuous responsibility for their patients. There is nothing to prevent the G.P.s in any locality making their own deputizing arrangements to whatever extent suits them. This is done in many areas with great success, and the existing insurance committees are in no way concerned, nor should they have any say in the matter. What Dr. Firman describes as "hypocritical bunkum" is an article of faith to most of his colleagues on the Representative Body. Would he desire his local executive council to have the right to interfere in the day-to-day working of the rota in his area? Would he like to have to obtain its sanction for every exchange of duty with a colleague?

Dr. Firman writes of the "genuine G.P.s," with whom he identifies himself, who comprise 90% (presumably of the total of G.P.s) and who are yearning for a chance of release from "blood, toil, sweat, and tears" and would therefore vote for reasonable fixed hours of duty had they the chance. Unfortunately it is quite impossible, so pressed are they by their professional duties, for them to spare one or two hours a year to attend meetings of their Divisions. A clear field is left for the remaining 10%—the phony G.P.s, whose betterable practices give them greater leisure. These elect from their number and instruct a representative, who is naturally cut off

touch with the desires of the backbone of the profession—the 90%—and who proceeds to sit on the Representative Body, which is already heavily weighted with consultants and specialists. This is apparently what Dr. Firman would have us believe, and yet nothing could be further from the truth. The general practitioners who form the majority of the R.B. are almost without exception in active practice, are drawn from all types of practice, and in many cases are the busiest practitioners in their own area. They serve their colleagues, often at considerable financial sacrifice, and they are oftener the targets for misinformed criticism than for bouquets. At no time have the consultants and specialists failed to support the interests of their G.P. colleagues.

Finally I should like to deprecate the gross exaggeration which is used in describing the work of the general practitioner. He works hard; during an epidemic he may be working all out for a few weeks. But there are times when the work is lighter and the leisure considerable. He is doing the work he has chosen and he can arrange it to suit himself. Personally I work at least as hard as any of my colleagues in this area, but if I came to consider that I had been "reduced to abject slavery" my self-respect would compel me to seek other employment either inside or outside the profession.—I am, etc.,

Preston.

F. M. ROSE.

SIR,—It seems appropriate now for us to review our attitude towards the National Health Service Act. A large measure of the support from within the profession for the principles of the Act undoubtedly rested upon the consideration that the proposed Health Service expressed the wishes of the large majority of the people. The principle that "I know what I want, therefore it must be good for me" is not always accepted as a sound one in the care of the sick. Surely in the wider field of a national health service it is just as true that we, the profession, are the experts relative to the lay electorate. And now there is evidence that the present Government no longer has such overwhelming support the wisdom of their earlier measures needs some review.

If the outcome of the present shrouded deliberations with the Minister does not allow further legislation to alter the Act in the essential items set forth by the Negotiating Committee, then we may thwart the purpose of the Act with a clear conscience. The termites of bureaucracy are multiplying within the structure of the present administration. Is the fabric still sound enough to bear the grave responsibilities of our ancient art?—I am, etc.,

London, E.C.1.

E. A. J. ALMENT.

SIR,—We have been recently reassured that the decisions of the Representative Meetings are being acted upon. Negotiations are going on with under-officials, and the Negotiating Committee is doubtless making a strong stand and doing its very best. But all preparations for the nationalization of doctors, patients, and hospitals are being energetically pushed forward, and young medical men are buying practices or partnerships at ruinous expense to avoid "direction," without even knowing the terms of the service that they may be forced into next July.

The Japanese kept America happy with negotiations up to the hour of Pearl Harbour. Snakes "negotiate" with rabbits before swallowing them. The sooner that we get a new plebiscite free from ambiguity the better. The voice of the profession has spoken through its representatives, and it spoke decidedly. Until now the British have always hated and resisted despotic controllers.—I am, etc.,

Hastings.

H. S. GABB.

SIR,—I don't want to add to the correspondence on the National Health Service Act, but I should like to call attention to one fact. The present Government has changed the old Mosaic commandment, "Six days shalt thou labour and do all thy work. But the seventh day . . . thou shalt not do any work" into "five days shalt thou labour . . . but on the sixth and seventh days thou shalt not do any work—except as overtime and paid accordingly."

The obvious deduction from this is that the contract of service with the medical profession should specify a five-day working

week and allow all work on Saturdays and Sundays to be "overtime," to be paid for by the person requiring such overtime at the usual rates for present-day private practice. Rather a brainy idea, I think, don't you?—I am, etc.,

Salford, Lancs.

STANLEY HODGSON.

SIR,—Dr. H. Firman's letter (Nov. 1, p. 100) is so much to the point and so straight from the shoulder that it seems surprising that it was published. Is the B.M.A. content to allow its members to feel that they would get more backing from a trade union—such as the coal-miners? Many of us will thank Dr. Firman (and the Editor) for saying what we think.—I am, etc.,

Glasgow.

J. E. KENNEDY.

### Working Day in the Services

SIR,—I feel that I must show some of your readers that the working day in the Services is not always as your correspondents make out. For the past nine months, until my admission to hospital last week, I have been M.O. at a central ordnance depot in the S.E. Midlands—a garrison of nearly 6,000 troops, including A.T.S. At no time during that period have I had less than 3,000 troops under my medical care, and for several weeks on more than one occasion I have looked after the entire garrison. While there were two of us we did night calls for seven out of fourteen days. When I was alone I did the night work continuously. Unlike "Captain, R.A.M.C." (Nov. 1, p. 101) I have had only 20 days' privilege leave in thirteen months.—I am, etc.,

ANOTHER CAPTAIN, R.A.M.C.

### Joint Tuberculosis Council

SIR,—I see in the *Supplement* of Nov. 1 (p. 100) that the Joint Tuberculosis Council is reported as recommending that physicians in charge of clinical teams and medical superintendents should have a status and remuneration identical with other consultants—e.g. general physicians. In addition, the J.T.C. recommends that there should be among the Regional Hospital Board's *specialist* officers a chief administrative and consultant tuberculosis officer. Presumably this officer is to be appointed to supervise the work of the physicians in charge of clinical teams and sanatorium superintendents.

I can understand the necessity for a chief *administrative* tuberculosis officer on the staff of the Regional Hospital Board, but why should he be expected to control the *clinical* work of those with full physician status? Or does the J.T.C. consider that *all* general physicians should have their clinical activities controlled by suitable "administrative and consultant" officers of the Regional Hospital Boards?—I am, etc.,

Kenton, Middlesex.

H. J. TRENCHARD.

### MEDICAL WAR RELIEF FUND FURTHER CONTRIBUTIONS NOT REQUIRED

The committee of the Medical War Relief Fund, the annual report of which for the year 1946-7 will be published shortly, has recently considered the financial position of the Fund and decided that it is unnecessary for supporters of the Fund to send further contributions. Applications for assistance are now relatively infrequent, and although some of the present beneficiaries are likely to need continued help for a number of years the committee is satisfied that by the time the existing balance of some £24,000 has been exhausted the Fund will have fully discharged the purely temporary function for which it was established.

In making this announcement the committee wishes once again to express its deep gratitude for the magnificent support received from the profession at home and overseas during the past seven years.

### RETURN TO PRACTICE

The Central Medical War Committee announces that Dr. Harold Parsons has resumed civilian practice at 25, Upper Wimpole Street, London, W.1. (Welbeck 9033.)

carried out automatically in an environment. A perfect plan might have been spoiled by a bad environment. A good environment might have made the best of an unsatisfactory plan.

There were two extreme views about the mind. The brain might make the mind in the same way that the heart circulated the blood alternatively, the mind might be independent of the body and the brain the executive machinery of the mind. Either theory could be argued equally persuasively, but it seemed more probable that the body and mind were different aspects of some reality which man would never comprehend. The causes of disease fell into three groups: genetic defects latent in the plan whence the individual was derived; adverse factors in the environment into which he had been born—mechanical injury, lack of food and vitamins, chemical poisons, and infections; and adverse action on the mind through normal organs of sensation. Action on the body or the mind led to reaction by the body or the mind. These actions together with the corresponding reactions constituted the different pathological processes of body or mind, which might lead to symptoms which brought the patient to consult his doctor.

Was there any evidence that primary disorders of the mind could lead to organic changes in the body in the same way that organic changes in the body could lead to changes in the mind? Symmetrical erythema of the skin was common in hysterical patients. Emotional states influenced the appearance of the mucous membrane of the stomach seen through a gastroscope. Fire walking seemed to be a fairly well established phenomenon. Under hypnosis slight trauma might produce structural changes in the skin. The mind could sensitize or desensitize the body to physical stimulation and therefore predispose to organic disease. Some diseases were almost entirely somatic, due to physical action on the body stimulating reaction by the body. Other diseases were almost entirely psychological, due to action on the mind stimulating reaction by the mind. There was also a group of diseases in the centre in which physical changes predisposed to emotional stimulation or emotional stimulation predisposed to physical changes. These diseases were neither entirely somatic nor entirely psychological. They were psychosomatic.

There was a good deal of evidence that states of mind predisposed to states of body and that emotional factors predisposed people of certain biochemical constitutions to diseases which were ordinarily regarded as entirely organic. One patient developed coronary thrombosis or hypertension when faced with business worries. Another developed thyrotoxicosis or ulcerative colitis when submitted to emotional stimulation. Other constitutions were made of stronger stuff.

He concluded by saying that science did not explain the conjunction of mind and body which constituted the patient. But medical education attempted to build a knowledge of clinical medicine entirely on a foundation of science. He was not saying that a doctor should not be scientifically trained. Of course he should. But observational medicine and applied science should be taught in parallel from the moment the student began to learn about anatomy and physiology. He should start in the wards sooner. Leaving out the mind at the preclinical stage inculcated an unbalanced attitude of mind.

## Association Notices

## Branch and Division Meetings to be Held

**BIRMINGHAM: CENTRAL DIVISION.**—At 154, Great Charles Street, Birmingham, Tuesday, Nov. 25, 8.15 p.m. Clinical meeting conducted by Dr. B. C. Tate.

**KENSINGTON AND HAMMERSMITH DIVISION.**—At West London Hospital, Hammersmith, W., Friday, Nov. 28, 8.30 p.m. Clinical meeting.

## Meetings of Branches and Divisions

## FIFE BRANCH

A complimentary dinner was given on Oct. 24 at Aberdour in honour of Dr. J. M. Johnstone, of Leven, by his colleagues in appreciation of his services as honorary secretary of the Branch from 1923 to 1947. The toast of "Our Guest" was proposed by Dr. John Isdale Greig, and a presentation of an inscribed writing-desk was made by Dr. F. McEwan Sinclair. Mrs. Johnstone was the recipient of a wristlet watch.

## MONMOUTHSHIRE DIVISION

Dr. Clark-Kennedy delivered a lecture on "Psychosomatic Medicine" on Oct. 23. He began by saying that the subject of his lecture was not of his own choosing. Moreover, he was not a psychologist. Rather he was a general physician who spent most of his time trying to avoid being driven into specialization. He had no practical tips to give his audience.

The term psychosomatic medicine implied disease of three kinds: psychological and somatic on either wing, psychosomatic in the centre. This conception was fundamentally correct. Everybody—and everybody was a potential patient—looked upon himself or herself as a conjunction of mind and body. But what was a mind? What was a body? A body from one point of view was a machine which converted the chemical energy of food into the potential energy of heat and movement. It differed from ordinary machines in being self-repairing and potentially self-reproducing. Whence did it come? It was the product of a genetic plan which had been

## NORTHERN IRELAND BRANCH

A Meeting of Branch Council of the British Medical Association, Northern Ireland, was held in the Whitla Medical Institute, Belfast, on Oct. 2, with Mr. McClure in the chair.

A letter was read from Dr. J. C. Johnston resigning his position as Assistant Honorary Secretary of the Branch owing to his taking up a position in England. Dr. R. A. Pyper was appointed to the position on the motion of Dr. T. A. Kean seconded by Dr. A. McQuiston.

Dr. Halliday read a letter from the Ministry of Health and Local Government referring to earlier consultations on the subject of the prohibition of the sale of medical practices, and placing before the Association two alternative proposals for arriving at a settlement. After discussion the meeting agreed to adopt the second method: the adoption of an individual basis of assessment for each doctor joining the service; the amount in each case shall be determined by reference to incomes for the three immediate pre-war years and for the year 1946 as confirmed by returns for income-tax purposes, with 1.9 years' purchase and a betterment adjustment (for pre-war figures) of 22%. But it was considered that the Minister should be requested to add the words "or such greater sum as Parliament may determine" after the words "two million pounds" in the Health Services Bill, Clause 8 (2).

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**County Borough Councils.**—Barnsley, Gateshead.

**Metropolitan Borough Councils.**—Fulham, Hackney, Poplar.

**Non-County Borough Councils.**—Dartford, Leyton, Redditch (limited to future appointments), Tottenham, WallSEND.

**Urban District Councils.**—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs.**—Motherwell and Wishaw.

LONDON SATURDAY NOVEMBER 29 1947

## THE VALUE OF B.C.G. VACCINATION IN CONTROL OF TUBERCULOSIS\*

BY

G. S. WILSON, M.D., F.R.C.P., D.P.H.

*Director of the Public Health Laboratory Service (Medical Research Council)*

accination with B.C.G. is now so universally applauded that any attempt to question its value is regarded almost as heresy. Despite this I propose in this address to act as devil's advocate, and to ask seriously whether the claims of Calmette and Guérin to canonization rest on an unshakable foundation. So far, B.C.G. vaccination has not been used in Great Britain, but there is an increasing demand from tuberculosis workers for its introduction. Before this step is taken let us be sure that it is fully justified. It is much easier to introduce a given measure into the public health practice of this country than to remove it once it has become firmly established. On a more suitable occasion I may dilate on what I call "public health anachronisms"—practices that are carried on now because they have been in use for the last thirty years or so, even though it has since been shown that they are of little or no value for the purpose for which they were originally intended. The accumulated weight of precedent is almost overpowering, and I therefore ask you to pause for a moment before committing yourselves to a practice that it may be very difficult subsequently to discontinue.

Let me make it clear that I have no prejudice either in favour of or against B.C.G. vaccination. I am merely interested in learning the truth about it. The published evidence, however, that I shall review briefly leads me to the conclusion that, though a strong presumptive case may be made out for the value of B.C.G., it is not yet convincing enough to justify the whole-hearted acceptance of this agent as a means of preventing tuberculosis in Great Britain.

### Vaccination of Infants with B.C.G.

Of the numerous investigations reported on the vaccination of infants with B.C.G. the majority have included no control group. Attempts to assess the value of the procedure have been made by comparing the tuberculosis death rate among the vaccinated infants with that among the infant population as a whole, either during the same period or during the previous five years or so, or with a group of ostensibly similar infants which have not been offered vaccination. Calmette (1928), for example, vaccinated one group of infants and compared the mortality among them with that among children of tuberculous parents and other children who were exposed to massive infection in their first year of life. As Greenwood (1928), however, pointed out, there were gross fallacies in these figures, and the comparison that Calmette made between the mortality in the vaccinated infants and that in the non-vaccinated was quite unjustifiable.

\*A paper read at the International Conference of Physicians on Sept. 12.

Wallgren (1934), working at Gothenburg, vaccinated every infant that was considered by the municipal dispensary to be in danger of infection from family contact. The result was striking. The infantile tuberculosis death rate fell from 3.9 per 1,000 in 1927, the year before this routine was introduced, to 0.3 per 1,000 in 1933—a fall of 92%. But, as Wallgren is the first to point out, it is impossible to assess the part played by B.C.G. in this achievement. The infants, for example, were separated from their parents for a variable period of time after vaccination, and in some instances were not exposed to infection till they were a year old. Moreover, the educational work of the dispensary nurses stimulated the interest of the mothers, so that they co-operated in shielding their infants from infection and made full use of the prophylactic means at their disposal. The ensuing fall of 92% in the infant mortality rate due to tuberculosis was almost certainly greater than any fall that might otherwise have occurred during the years 1928 to 1933. It is fairly safe to conclude, therefore, that the very thorough measures taken by Wallgren were mainly responsible for the result observed, but it is quite impossible to say what part in this result was played by B.C.G.

### Chicago Investigation

Two lots of workers have included a special control group in their series. At Chicago, Rosenthal, Bland, and Leslie (1945) carried out an investigation at the Cook County Hospital. Expectant mothers desiring vaccination for their babies were asked to sign a consent card. X-ray studies were then made of the entire household to find out whether any of the members was suffering from tuberculosis. The child of every alternate mother who had consented was vaccinated with B.C.G. by the multiple-puncture method, usually when it was three to seven days old. The children were kept under observation and were tuberculin-tested and x-rayed at intervals.

The infants were divided into those having no contact with known cases of tuberculosis and those known to be exposed to contact. In the non-contact group 1,204 vaccinated children were observed and 1,213 control children. Among the former there were three cases of tuberculosis and one death, among the latter 23 cases and four deaths. In the contact group, infants who were in contact with closed cases of tuberculosis were removed from their homes for six weeks to three months; those who were in contact with open cases were permanently removed and kept in a foster-home. Among 98 newborn infants who were in contact with tuberculosis after vaccination there was one case of tuberculosis and no death; among 63 controls there were four cases and three deaths. Taking the

contact and non-contact groups together, we see that there were four cases and one death in the vaccinated group as opposed to 27 cases and 7 deaths in the control group (Table I).

TABLE I.—*B.C.G. Vaccination of Infants in Chicago (Rosenthal, Bland, and Leslie, 1945)*

Group	Subgroup	No. of Children	No. of Cases of Tb.	No. of Deaths from Tb.
Non-contact	Vaccinated	1,204	3	1
	Control	1,213	23	4
Contact	Vaccinated	98	1	0
	Control	63	4	3
Contact and non-contact together	Vaccinated	1,302	4	1
	Control	1,276	27	7

Superficially these results are impressive, but before accepting them at their face value one would like to have information on a number of points that are left vague. (a) The follow-up apparently did not start till three to seven months after vaccination, by which time it would seem that many infants in both groups had died; it would be interesting to know more about these infants, since they are completely ignored in the final figures; (b) the total deaths from all causes were 21 in the vaccinated and 21 in the control group, but, apart from those due to tuberculosis after the follow-up had started, there is no information on when they occurred or what they were due to; (c) it is said that observations were made on the non-contact group during a period of seven years and on the contact group during a period of three to four years, but it is not stated what was the average duration of observation among the vaccinated and the control groups; (d) there is no information on whether the radiologist who read the x-ray photographs knew whether the child had been vaccinated or not; (e) in the early part of the investigation on the contact group there were no controls; the vaccinated children during this period, however, are included in the comparison; (f) it is not clear whether in the contact cases the controls were isolated in exactly the same way and for the same length of time as the vaccinated.

The results of this investigation suggest that B.C.G. vaccination may lead to some lowering in the morbidity and the mortality rates in infants, but without more precise information on the method of conducting the investigation it would be unwise to regard this as more than a very tentative conclusion.

#### New York City Investigation

In New York City a more or less similar investigation was carried out, with results that are both interesting and illuminating. Observations were made on children in tuberculous families. Practically all children came under observation before they were a year old, and no child over one month old was accepted unless it was both tuberculin and x-ray negative. Except during the first two years of the trial, when the vaccine was given by mouth, all inoculations were made intracutaneously. After January, 1933, the B.C.G. dose was standardized at 0.15 mg. Between 1926 and 1932 the children were divided into two groups, according to whether the mother wished her baby to be vaccinated or not. Under these conditions the children of the more intelligent and co-operative parents tended to be vaccinated and those of the careless and less intelligent parents to constitute the control group. From 1933 onwards the mode of allocation into groups was altered. Consecutive mothers were asked whether they would like to have their children vaccinated. Those that refused were not considered any further. To the children of the mothers who were willing to accept vaccination B.C.G. was given alternately without selection. Under these conditions both the vaccinated and

the control groups comprised children who came from the same class of co-operative parents. The results of this investigation, as described by Levine and Sackett (1946), are given in Table II.

TABLE II.—*B.C.G. Vaccination of Infants in New York City (Levine and Sackett, 1946)*

Period	Alternate Selection	Vaccinated Group			Control Group		
		No. of Children	No. of Deaths from Tb.	Tb. Mortality %	No. of Children	No. of Deaths from Tb.	Tb. Mortality %
1926-32	No	445	3	0.67	545	18	3.30
1933-44	Yes	566	8	1.41	528	8	1.52

It will be observed that during the first period, when the method of selection was faulty, the tuberculosis mortality in the control group was five times that in the vaccinated group; but during the second period, when strict alternate selection was practised, the tuberculosis mortality in the two groups was almost identical.

These results serve to show how important it is, when carrying out a controlled investigation on human subjects, to do everything possible to ensure that the vaccinated and the control children are similar in every respect, including such factors as age, race, sex, social, economic, and housing conditions, intellectual level and co-operativeness of the parents, risk of exposure to infection, attendance at infant welfare or other clinics, and treatment when ill.

Levine and Sackett's findings are open to criticism on three points. First, no records are given of the morbidity as opposed to the mortality, in the two groups. Secondly the diagnosis of tuberculosis in 3 of the 11 fatal cases in the B.C.G. group was doubtful. It may be pointed out however, that only one of these occurred in the 1933-4 period, so that even if this case was excluded it would not have much effect on the final results. Moreover, a similar deduction might have to be made for unconfirmed diagnosis in the control group, though the number of such cases is not stated. Thirdly, the most serious criticism is that the infants were not usually separated from their tuberculous parents before and after vaccination, with the result that some infants may have been actually infected before they were vaccinated and others may have been exposed to infection before immunity following vaccination had had time to develop. It is difficult, as the authors themselves admit, to know how much allowance to make for this factor. Any attempt to make such allowance would be largely guesswork. It is probably safer to conclude that though B.C.G. vaccination of the infants of tuberculous parents might be of value if accompanied by the necessary amount of segregation to ensure that exposure to infection did not take place till immunity, as judged by the tuberculin test, had been established, under ordinary conditions in which the infants are brought up in a tuberculous environment it seems to confer little, if any, protection.

The results of this investigation do not support those of the Chicago experiment, and we are therefore left without any convincing evidence that B.C.G. vaccination of infants by itself confers any considerable degree of protection against the risk of death from tuberculosis in early life.

#### Vaccination of Nurses with B.C.G.

The two main investigations on the B.C.G. vaccination of nurses are those of Heimbeck (1936) in Norway and of Ferguson in Canada (1946). Since Ferguson included a control group in his series, and merely judged the efficacy of the B.C.G. vaccination by a diminution in the tuberculosis morbidity of nurses during the investigation it

relation to that in nurses during the previous 5-year period, his results, however suggestive, cannot be accepted without question. It is impossible to be certain that the conditions during the period of the investigation were identical with those before vaccination was started, and conclusions drawn from comparisons of this sort are liable to be misleading.

Of Heimbeck it is probably true to say that he has done more than any other single person to convince tuberculosis workers of the value of B.C.G. vaccination in protecting against the disease in young adults. His conclusions are based on two main contentions: (a) that tuberculin-negative nurses are more liable than tuberculin-positive nurses to contract tuberculosis; and (b) that among tuberculin-negative nurses vaccinated with B.C.G. the tuberculosis morbidity is lower in those who become tuberculin-positive as the result of vaccination than in those who do not.

Heimbeck's work was carried out on probationer nurses entering the Ullevål Communal Hospital at Oslo during the years 1924 to 1935. Every nurse was submitted to a von Pirquet test on entry. This was repeated periodically on those that failed to react. From 1927 onwards the negative reactors were vaccinated subcutaneously with B.C.G. As a result rather over two-thirds became von Pirquet positive. The two groups were followed up for two to three years, and the number of cases of tuberculosis developing was noted. The results given in Table III are restricted to cases of pulmonary tuberculosis, the multiple minor manifestations, including erythema nodosum, being omitted.

TABLE III.—B.C.G. Vaccination of Nurses in Oslo (Heimbeck, 1936)

Group	Subgroup	No. of Nurses	Nurse Observa- tion Years	No. of P.T. Cases	Rate per 1,000 Observa- tion Years
von Pirquet positive on entry	(a)	625	2,659	4	1.5
von Pirquet negative on entry	(b) Not vaccinated	280	561	13	23.2
	(c) Vaccinated and became positive	287	910	1	1.1
	(d) Vaccinated and remained negative	107	204	1	4.9

P.T. = Pulmonary tuberculosis.

It will be seen first of all that the nurses in subgroup *b*, who were von Pirquet negative and were not vaccinated, suffered much more heavily from pulmonary tuberculosis than those in subgroup *a*, who were initially von Pirquet positive. The difference between groups *c* and *d* is very much less, and by the ordinary statistical tests would not be regarded as significant.

Before regarding the difference between groups *a* and *b* as conclusive two points must be noted. In the first place the girls had been subjected to a careful medical examination before being accepted as probationers, and any girls with a history of tuberculous disease or showing evidence of tuberculosis were rejected. The effect of this would be to reduce the number of subjects in group *a* who developed pulmonary tuberculosis during their training period. Secondly, instead of following up initially positive and initially negative nurses over the same length of time, Heimbeck transferred in his analysis the initially von-Pirquet-negative nurses to the positive group within one year of their primary infection. The result was that if the nurse developed symptoms of tuberculosis within a year of her primary infection she appeared among the initially negative group that became tuberculous. If, on the other hand, she showed no evidence of tuberculosis for a year or more she went to swell the number of the initially von-Pirquet-positive group that remained free. Since the majority of tuberculous lesions in initially tuberculin-negative nurses seem to occur during the year following the appearance of a positive reaction (Israel, Heitherington,

and Ord, 1941; Daniels, 1944), the effect of this transfer must have been to increase the disparity between the two groups and weight the odds in favour of the initially tuberculin-positive group. (It is a little doubtful how the groups were finally constituted, but in this account I have adhered strictly to that given in Heimbeck's paper).

#### Vaccination of Primitive Peoples with B.C.G.

Starting in 1935, a carefully controlled study, lasting for six years, was made by Aronson and Palmer (1946) among North American Indian children and young adults. The subjects, who ranged from 1 to 20 years of age, were tuberculin-tested with P.P.D. (purified protein derivative). Those who failed to react to 0.005 mg. were divided at random into two groups.

The first group, which comprised 1,550 persons, were injected intracutaneously with 0.1 or 0.15 mg. of B.C.G.; the second group, which comprised 1,457 persons, were injected with 0.1 ml. of sterile saline. An initial x-ray film was taken to exclude those with evidence of pulmonary tuberculosis, and the inoculated subjects were re-examined annually by the tuberculin test and by radiography. The expert who read the x-ray films did not know to which group any given subject belonged. Analysis showed that the two groups were very similar in age, amount of exposure to tuberculous infection, and completeness of the follow-up. The results are summarized in Table IV.

TABLE IV.—B.C.G. Vaccination of North American Indian Children and Young Adults (Aronson and Palmer, 1946)

Group	No. of Subjects	No. Develop- ing N.P.T.	No. Develop- ing P.T.	Tb. Case Rate per 1,000 Person-years*	No. of Deaths from all Causes	No. of Deaths from Tb.
Vaccinated	1,550	9	8	2.0	34	4
Non-vaccinated	1,457	48	20	9.0	60	28

\* Pleural effusion and hilar gland enlargement excluded.

As in the record of Heimbeck's investigations, I have purposely omitted cases of pleural effusion and enlarged hilar glands from the pulmonary tuberculosis figures so as to make the comparison between the vaccinated and control groups more definite. It will be noted from Table IV that the incidence of pulmonary, and still more of non-pulmonary, tuberculosis was considerably higher in the group receiving saline than in that receiving B.C.G., and that the tuberculosis mortality was seven times as high in the control as in the vaccinated group.

These figures are very suggestive, but it may be questioned whether the conclusions drawn from them can legitimately be transferred to civilized peoples having a higher degree of genetic immunity and exposed, as a rule, to a lower risk of infection. Some indication of the lack of similarity between the North American Indians and the ordinary population of the United States is afforded by the great difference between them in the incidence of non-pulmonary tuberculosis. In Aronson and Palmer's control group, for example, the ratio of non-pulmonary to pulmonary tuberculosis was about  $2\frac{1}{2}$  to 1, whereas in the United States as a whole, during the years 1935-41, the ratio among persons of 1 to 25 years of age, as judged by the recorded deaths (figures for incidence not available), was about 1 to 5. It is, in fact, doubtful whether the same proportionate degree of protection is likely to be conferred by vaccination in a community such as our own as in a race of people in which the natural history of tuberculosis is so very different. In this connexion it may perhaps be well to remember the law of diminishing returns.

### Discussion

Within such a short compass as is here allowed it is impossible to do justice to the full claims for B.C.G., but I have selected for review those investigations which come more closely to a controlled laboratory experiment than any others. Even so, it must be admitted that the results of all but one of these investigations are inconclusive. What we have got to decide is whether the routine use of B.C.G. in this country would diminish the total tuberculosis incidence and mortality. It is clearly impossible to estimate numerically the advantage that such a course would have, or even to be sure that it would have any advantage at all. Assuming, however, that B.C.G. does afford some measure of protection against the development of clinical tuberculosis, let us consider the difficulties and disadvantages that its use might entail.

(1) B.C.G. is a live vaccine, and should be used within a week of its preparation. This means that very great care has to be taken in its preparation to avoid contaminants, and in its distribution to make sure that a high proportion of the organisms are alive at the time of injection. (2) The virulence of B.C.G. is not fixed. If it is too virulent harmful reactions may occur in those who are injected; if it is not sufficiently virulent the degree of protection it affords will be reduced. (3) The injection has to be made intracutaneously with considerable care. If the vaccine is injected too deeply serious ulceration may occur at the site of injection in a high proportion of subjects and persist for weeks or months, sometimes accompanied by suppuration of the regional lymphatic nodes. Even if the injection is made strictly into the superficial layers of the skin a small local ulcer may normally be expected to develop (Holm, 1946). It is true that some of the disadvantages of intracutaneous injection are said to be avoided by the multiple-puncture method (Birkhaug, 1944), but too little experience of this method is as yet available to justify the claims of its author. (4) The infants of tuberculous mothers must be separated at birth, or, if taken away at a later age, they must be separated for at least six weeks to exclude the possibility of their having already acquired tuberculous infection by the natural route before they can be vaccinated. (5) After vaccination they should be separated from their parents for two to three months in order to allow a reasonable degree of immunity to develop. (6) Infants separated in this way and kept in residential nurseries may be exposed to serious risk of cross-infection, and develop pneumonia or gastro-enteritis, either of which may prove fatal. (7) Since the B.C.G. organisms die out in the human body, it is desirable to revaccinate the child at intervals to ensure the continuance of immunity.

Taken individually, none of these disadvantages need be regarded too seriously, but taken together they do combine to render B.C.G. vaccination very much more formidable than vaccination against smallpox or diphtheria. Even if it is assumed that B.C.G. is of value it must be asked whether it should be applied to the whole population or only to selected portions of it. When it is realized that in England and Wales the chances of dying from tuberculosis in the first year of life are 1,740 to 1 against, I think we may conclude that universal vaccination of the infant population is out of the question. If it was pressed it would almost certainly result in the partial substitution for highly reliable prophylactic procedures, such as vaccination against smallpox and diphtheria, of the very much more doubtful procedure of B.C.G. vaccination, since a considerable proportion of parents would refuse to have their children inoculated with all three agents—particularly if the B.C.G. vaccination, which would normally be given first, was followed by any serious local disturbance. The alternative, therefore, would be to restrict B.C.G. vaccination to those groups of the community, such as the infants and children of tuberculous families, and medical students and

nurses, who are exposed to an unusually high risk of developing tuberculosis (see Cox, 1929; Ridehalgh, 1944; Daniels, 1944). If it is adopted for these groups, the infants and children should be separated for a time from their tuberculous parents for the reasons that have already been stated, and care should be taken that medical students and nurses are kept away from any known source of tuberculous infection for six to twelve weeks after vaccination.

Before we commit ourselves to adopting this course would be of great help if a properly controlled investigation on human beings could be carried out in this country. The difficulties of such a task are not underestimated, but unless we do attempt to measure the advantage so gained we shall never know the real value of B.C.G. vaccination and we may not even know whether it is of any value at all in the circumstances in which we use it. It is suggested that a suitable trial might be carried out on probation nurses entering the London and larger provincial hospitals. The results of the Prophit investigation (Ridehalgh, 1944; Daniels, 1944) have shown that about 20% of these nurses are tuberculin-negative at the start of their training course. Forty thousand nurses should therefore include 8,000 who are suitable for investigation. Alternate tuberculin-negative nurses should be vaccinated with B.C.G. and the remainder should receive some control fluid indistinguishable from it. If 0.5% of the nurses in the control group develop pulmonary tuberculosis annually, and if the average period of follow-up is two years, the number of cases in this group should amount to 40. If the B.C.G. vaccination is really effective the number of cases in the vaccinated group should be small enough to render the difference between the two groups significant. It is realized, of course, that the 40,000 nurses required initially for testing could not be obtained at once, but if 4,000 or 8,000 were taken into the investigation every year an answer should be forthcoming in about five to ten years.

In an investigation of this sort I feel that the comparison between the two groups should be confined to pulmonary tuberculosis of reasonable severity. I shall not attempt to define this more accurately now. My point is that if minimal pulmonary, glandular, and other manifestations of tuberculosis are included it may be possible to swell the number of tuberculous cases in the control group, as in Heimbeck's (1936) figures, and make out a theoretically convincing but practically unimportant case for B.C.G. vaccination. Should such a properly controlled trial prove impracticable, then I would suggest that B.C.G. vaccination should be liberated for use only under strictly defined conditions ensuring the most careful follow-up of the vaccinated subjects with some degree of central supervision.

If B.C.G. vaccination is to be undertaken the gains must be commensurate with the disadvantages; and unless it can be shown that the morbidity and, particularly, the mortality from tuberculosis are substantially lowered should regard it as doubtful whether routine vaccination of all tuberculin-negative nurses and medical students was worth while adopting. When it is realized that during the whole of the Prophit survey, which lasted for ten years only two nurses died from tuberculosis, giving an annual mortality rate one-third of that for the female population of corresponding age in England and Wales, it may be wondered whether the relative degree of immunity that B.C.G. vaccination may possibly confer is likely to be of any substantial value in practice, and whether almost equally good results might not be achieved by measures designed to protect nurses from undue exposure to infection.

Infants and children in tuberculous families present a rather different problem. Presumably the best answer, as a rule, is to remove the tuberculous member of the family from the house; but if this is not practicable the children should be removed. This has got to be done temporarily in any case if they are to be vaccinated, as all the protagonists of B.C.G. insist that separation for a time is necessary if the best results are to be obtained. If temporary removal has got to be practised, it is surely worth while considering whether separation should not be continued till the tuberculous member of the family has been cured, has died, or has been admitted to an institution for chronic cases.

One more word. Is it really worth while vaccinating infants at birth? We are still ignorant of the time the antibody-producing mechanism takes to reach maturity, but we have reason for believing that the tissue response to antigenic stimuli during the first few months of life is less than it is by the end of the first year. That is why inoculation against diphtheria is usually delayed till nine to twelve months after birth. Is there any reason for believing that the tissue response to a vaccine against the tubercle bacillus is likely to be more active than that against other antigens? If not, would it not be better to remove the infant from its tuberculous home at birth and delay vaccination with B.C.G. till it is at least 6 months of age? That this objection is not purely hypothetical is borne out by the finding that infants at birth require larger doses of B.C.G. than older infants to render them tuberculin-sensitive, and take a longer time to become allergic (Wallgren, 1947).

### Summary and Conclusions

Investigations are reviewed in which a control group of persons was studied along with a B.C.G. vaccinated group.

Though a presumptive case for the value of B.C.G. vaccination has been established, it is concluded that the documentary evidence so far available is insufficient to allow any estimate to be made of the degree of protection it affords or even to prove conclusively that, in a civilized population, it has any protective effect at all.

Some of the disadvantages of B.C.G. are enumerated, and it is argued that, unless the gains from its use are likely to be substantial, B.C.G. vaccination in this country may not be worth while undertaking.

Since the risk of dying from tuberculosis in the first year of life is so small, universal vaccination of infants is clearly out of the question, and vaccination, if it is used, should be restricted to specially exposed groups, like nurses, medical students, and children in tuberculous families.

It is pointed out that the tuberculosis mortality among nurses in the Prophit survey was only a third of that among the corresponding female population in England and Wales; and it is doubted whether the relative degree of immunity that might be conferred by B.C.G. vaccination would have any greater effect in lowering the mortality than measures designed to shield nurses against undue risk of exposure to tuberculous infection.

It is further pointed out that infants and children of tuberculous parents must be separated from their homes for two to three months after vaccination with B.C.G. in order to allow immunity to develop; and it is questioned whether it might not be wiser to prolong this separation till the infecting member of the household has been cured, has died, or has been removed to an institution for chronic cases.

Since the normal antibody-producing mechanism does not seem to reach maturity till towards the end of the first year of life it might be better, if B.C.G. is to be used, to remove the infant from its tuberculous home at birth and delay vaccination with B.C.G. till it is at least six months of age.

A plea is entered for the carrying out of a properly controlled trial of B.C.G. vaccination in Great Britain, or, if this

is impracticable, for the liberation of the vaccine only under strictly defined conditions.

I am indebted to Prof. A. Bradford Hill for help in assessing the evidence in some of the investigations reviewed in this paper.

## SYMPATHECTOMY AND INTRASPINAL ALCOHOL INJECTIONS FOR RELIEF OF PELVIC PAIN\*

BY

J. P. GREENHILL, M.D.

Professor of Gynaecology, Cook County Graduate School of Medicine, Chicago

Pain may be either acute or chronic. In women acute pelvic pain is not infrequent, and may be due to such causes as rupture of an ectopic pregnancy or of a corpus luteum cyst, or sudden torsion of an ovarian cyst. Such causes of pain may be relieved instantly and dramatically by a surgical operation. Likewise, in many cases in which the pain is chronic, as in pelvic inflammatory disease and endometriosis, an operation that removes the source of the pain brings relief. However, there are many women who suffer severe pain and in whom removal of its cause is either impossible or inadvisable. In this category are women with inoperable carcinoma of the uterus or severe dysmenorrhoea, women subjected to repeated unsuccessful laparotomies for the relief of pelvic pain, and young women with endometriosis who should not be castrated.

For the intractable pain associated with carcinoma of the uterus, particularly of the cervix, most physicians prescribe an opium derivative such as morphine, "pantopon," codeine, or "dilaudid." These drugs are temporarily helpful, but eventually the patient becomes refractory to them. The reasons for this inadequacy are: (1) the potential tolerance for the drugs increases enormously, so that larger and larger doses are required, resulting in a constant increase in expenditure for the drugs until the poor patient can no longer afford them; (2) in some people the opium derivatives produce nausea and vomiting; and (3) a few individuals become drug addicts.

To secure more or less permanent relief from the excruciating pain which is associated with cancer of the uterus, severe dysmenorrhoea, endometriosis, and the distressing pain of unknown origin, I recommend two useful procedures. The first is pelvic sympathectomy, or removal of that part of the sympathetic nerve plexus known as the presacral nerve or the superior hypogastric plexus. The second is intraspinal injection of alcohol.

\*Read before the Oxford Postgraduate School of Medicine on July 14, 1947.

Sympathectomy is an operation that any surgeon may perform readily. The risk involved is slight, the technique is not complicated, and local infiltration analgesia may be used for a large part of the operation and in some instances for the whole of it. Furthermore, since the abdomen must be opened to carry out this procedure, it enables one to determine the extent of the growth of endometriosis, the amount of carcinomatous involvement, and any pathological process not discovered before the operation.

Of the two questions that are rightfully raised the first is whether the fibres of the sympathetic system are really sensory. Ranson (1926, 1930) confirmed the proof that was offered by Edgeworth. All the motor fibres degenerate, but the sensory fibres remain intact if the roots of the spinal nerves are cut proximal to the spinal ganglia.

Vasoconstriction of the blood vessels of the internal genital organs and inhibition of the secretion of the genital glands are produced by the hypogastric plexus, whereas the parasympathetic nerves have an opposite effect. The normal menstrual cycle is not altered by section of the superior hypogastric plexus nor does it interfere with uterine contractions during labour; neither does section produce glandular atrophy or any disturbance in the motor function of the bladder or rectum. Therefore the nerve fibres of the superior hypogastric plexus are sensory and not motor. Their function is to carry sensations from the internal genital organs to the medullary centres. Hence resection of the portion of the superior hypogastric plexus above the hypogastric ganglion is a simple way of relieving a patient of severe pain arising in the pelvic organs.

The second question concerns any possible harm that may follow removal of a portion of the sympathetic nervous system. Ranson (1926, 1930) states that Cannon and his students completely removed "the sympathetic chain on both sides, from the highest cervical to the lowest sacral ganglion. Such completely sympathectomized cats have lived under laboratory conditions for many months. Everything indicates that almost any part of the sympathetic system can be removed without seriously endangering life."

### Indications for Pelvic Sympathectomy

Pelvic sympathectomy will almost completely relieve the intractable pain in about half of the cases of Group III and Group IV carcinoma of the cervix, and it will partially relieve many more. The operation (Greenhill and Schmitz, 1933) should be performed as a prophylactic measure in all cases in which a laparotomy is done for carcinoma of the cervix of the corpus uteri. Should recurrence of the cancer follow the procedure there will be considerably less pain than if the sympathectomy had not been performed. It has been reported by de Sousa Pereira (1946) that in women with cancer of the cervix subjected to pelvic sympathectomy the results of the post-operative irradiation are better than if sympathectomy had not been performed, because the vasodilatation produced by the sympathectomy improves the circulation. Pelvic sympathectomy is also indicated in selected cases of primary dysmenorrhoea in which all medication, including hormones and minor surgical measures, has been tried without avail. The results in dysmenorrhoea are excellent. I have not yet had a failure in my dysmenorrhoea cases (Greenhill, 1940).

Another but infrequent indication for pelvic sympathectomy is persistent pain in the lower abdomen not relieved by repeated laparotomies. Occasionally women are seen who have had several laparotomies for the relief of pain. Usually the first operation was an appendicectomy, then an operation for an ovarian cyst, and then one or more operations for adhesions. In such women, even if the cause of

the pain is not removed, dramatic relief will follow pelvic sympathectomy.

Still another field of usefulness for pelvic sympathectomy is in cases of endometriosis in which conservatism is advisable. Of course if both ovaries are removed the endometriotic areas cease to grow. However, spaying is not desirable in young women. In all instances in which conservatism is desired a pelvic sympathectomy should be performed. The operation not only relieves pain but also seems to have some beneficial effect on the endometriosis, probably due to the vasodilatation which follows the procedure.

### Technique of Pelvic Sympathectomy

The operation to be described was recommended by Cotte (1931, 1932). Since some patients who are subjected to this operation are poor surgical risks it is best to open the abdomen under direct infiltration analgesia. The rest of the operation is readily performed under a short ethylene or ether anaesthesia or even under infiltration analgesia. The patient is placed in the Trendelenburg position after a midline incision of 10-12 cm. has been made from the umbilicus down towards the pubis. After the peritoneal cavity is opened the small intestine is packed off and the sigmoid and rectum are pushed to the left side and held there with a wide retractor. Then the uterus, adnexa, and bladder may be inspected readily and palpated to determine the extent of the pathogenic processes. One may also detect a complication that can be remedied surgically. The area of the two lower lumbar vertebrae and the upper part of the sacrum is exposed. In some thin women the presacral plexus can be seen immediately beneath the peritoneum. Whether or not the plexus can be seen, the parietal peritoneum above and in the middle of the sacral promontory is elevated and incised. This incision is extended upwards and down along the sacrum for 4-5 cm. A layer of fibro-cellular connective tissue covered by adipose tissue will be exposed when the peritoneal flaps are pulled aside. This tissue can be separated easily from the peritoneum and the lower end of the aorta without hazard. The presacral plexus lies in this layer of tissue. With an aneurysm needle the tissue is elevated at the bifurcation of the aorta and the dissection is carried to a still higher level. As this is done it will be observed that in most instances the tissue spreads out triangularly. The middle sacral artery should be pushed away from the nerve, but if it is injured it can be ligated readily.

After the dissection is carried as high as desired the layer of nerve tissue is separated from the underlying tissue beyond the sacral promontory into the pelvic cavity. The plexus in this area is divided into two hypogastric nerves; hence it is necessary to dissect each nerve separately. At least 2 or 3 cm. of each hypogastric nerve should be resected in addition to 4 cm. or more of the superior hypogastric and the intermesenteric plexuses. The layer of fibrous tissue containing the hypogastric nerves is much more resistant than that containing the presacral plexus. As the dissection progresses nerve filaments projecting outward will be encountered. These should be followed as far laterally as possible before they are cut. In most instances ganglia will be included in the resection. It is preferable to remove the dissected tissue in one piece. It is not necessary or advisable to ligate the presacral plexus or the hypogastric nerves before cutting them, because only insignificant vasa nervorum are in intimate contact with them. Rarely is bleeding encountered that requires more than simple temporary pressure to check it. (When the mesosigmoid is extremely short, injury to the inferior mesenteric vessels must be avoided.) After the nerve tissue is resected the

posterior parietal peritoneum is sutured with plain catgut and the abdominal wall is closed in the customary way. Since women with inoperable carcinoma are usually cachectic and therefore show poor wound healing, silkworm gut or other permanent suture material should be used in closing the abdominal wall.

### Intraspinal (Subarachnoid) Alcohol Injections

The injection of alcohol into nerves for the relief of pain has been in use for many years, but not until recently has it been employed for the relief of pelvic pain. In 1931 Dogliotti recommended subarachnoid injection of alcohol for the relief of pain. He chose the subarachnoid space because this area is the most central one for attacking the nerve roots and its injection prevents all painful peripheral stimuli from reaching the medullary centres, even if the stimuli act at the level of the spinal ganglia, the intervertebral foramina, or the spinal roots. Absolute alcohol is the preferred drug because it has no secondary toxic effects. It is easily and rapidly diffused and has a specific gravity much lower than that of the spinal fluid, hence its rise immediately affects the nerves. Most of Dogliotti's patients had sciatic pains, but not one of them had carcinoma of the genitals. The first reports on the use of intraspinal alcohol injections for cervical carcinoma were published almost simultaneously in 1934 by Saltzstein and by Stern.

In 1934 I began using intraspinal injections of alcohol for excruciating pain associated with malignancy in the female pelvis (Greenhill and Schmitz, 1935, 1936). In a series of well over 100 cases of Group III and Group IV carcinoma of the cervix treated by Schmitz and myself complete relief was obtained in about 60% and partial relief in 10%. The relief usually lasts many months—sometimes until the patient dies of the cancer. The only patients with inoperable carcinoma of the cervix who are not suitable candidates for intraspinal alcohol injections are those whose pain is in the renal area and in the parametrium from stricture of the ureter associated with hydro-ureter and hydronephrosis. The technique of intraspinal (subarachnoid) injection of alcohol is simple, and it is performed quickly and with little discomfort. However, since there is a possibility that in some cases the spinal cord may be injured, the procedure should be used only in cases of cancer.

### Technique of Intraspinal Alcohol Injection

No preliminary medication is given, because observation of the immediate effects of the injection is desired. The pain in most patients with advanced carcinoma of the pelvic organs is more intense on one side than on the other. The patient is placed on the side opposite to that in which most of the pain is present. A pillow or pad is placed under the pelvis and side to elevate the sacral and lumbar portions of the spine, the back is arched as much as possible, the body is turned somewhat ventrally, and the head is lowered slightly. By placing the patient in this position the sacro-lumbar area of the spine is raised to the highest level, and at the same time the posterior or sensory nerve roots are caused to lie horizontally. The anterior or motor nerve roots come to lie in a plane that is usually out of reach of the alcohol. Even if the motor nerves are not removed from the field of the alcohol, as occurs in the cauda equina, they are often not affected, since sensory nerves are more susceptible than motor fibres to the effects of alcohol. This is because the sensory nerves have less myelin.

The patient should be held in the proper position. A weak solution of iodine or other antiseptic is applied over the

lumbar and upper sacral areas. Injection is made in the second, the third, or (usually) the fourth lumbar interspace with an ordinary lumbar-puncture needle with a stylet. Procaine ("novocain") is injected into the skin before the needle is inserted into the desired interspace just as for an ordinary lumbar puncture. After the needle is in the subarachnoid space, as shown by the flow of spinal fluid, 0.75 ml. of absolute or 95% alcohol is injected into the cerebrospinal fluid. For this purpose it is best to use a tuberculin syringe to ascertain that not more than 0.75 ml. of the solution is injected. Furthermore, the alcohol must be injected very slowly, drop by drop: about two minutes is allowed for the injection of the 0.75 ml. The alcohol rises and immediately surrounds the posterior roots because its specific gravity is about 806, whereas that of the spinal fluid is 1007 to 1001. No spinal fluid should be drawn into the syringe to mix with the alcohol. After the injection is made the needle is withdrawn and the puncture hole is covered with sterile gauze and adhesive tape.

Before the injection is completed the patient will complain that the upper leg feels numb or hot and that she cannot move her leg. The numbness is almost routine after the injection, but it disappears spontaneously after a few hours or days in most instances. In spite of what the patient says concerning her inability to move the leg, when she is requested to do so she will encounter no difficulty. At the same time that the patient remarks about the numbness she also says, either voluntarily or in answer to a query, that the pain has disappeared. The results are better if the patient is permitted to lie on the side for some time. Therefore she should be kept on the side for two hours after the injection; then she is permitted to get up and walk around. At times a patient may find difficulty in getting up from a chair because her "leg is asleep." In other instances the leg feels heavy and the patient experiences some trouble in walking up steps because the knee flexes readily. These sensations usually disappear in a few hours, although in some patients they may be present for a number of weeks.

Nearly all ambulatory patients may be permitted to go home within three hours after the injection without ill effects. However, it may be best to keep a patient in a hospital for twenty-four hours after the injection. I should like to emphasize that the intraspinal injection of alcohol may be carried out easily in a patient's home. This is important; since many individuals with cancer are bedridden at home, and there is no need to subject them to the inconvenience and expense of transporting them to office or hospital. If the patient has pain on both sides an intraspinal injection of alcohol is made a week later with the patient lying on the opposite side. The same amount of alcohol is injected.

### Comparison of Results

An analysis of my cases of carcinoma of the cervix treated by pelvic sympathectomy and by alcohol injections revealed that better results were obtained with intraspinal injections. In addition to the greater percentage of patients relieved by injections of alcohol, this procedure is far simpler than sympathectomy, since it does not require a stay in hospital. Therefore I believe that all women who have severe pain associated with carcinoma of the cervix should have an intraspinal injection of alcohol. More than half of such women will obtain complete relief and in a few others the benefit will be partial.

Intraspinal injections of alcohol should be used only in women with cancer, because there is definite risk of injury to the spinal cord. For women who have excruciating pain due to menstruation, endometriosis, and unknown causes pelvic sympathectomy is preferred.

## Summary

I have briefly described two procedures which may be used to relieve intractable pelvic pain in women. One of these—pelvic sympathectomy—has proved most helpful in cases of carcinoma of the uterus, dysmenorrhoea, endometriosis, and pelvic pain of unknown aetiology. In inoperable cases of cancer pelvic neurectomy is helpful not only for the relief of pain but also as a prophylactic procedure at the time of hysterectomy. Likewise, pelvic sympathectomy is of great benefit in cases of endometriosis treated conservatively, not only because it relieves the pain but also because it apparently improves the endometriosis. Nearly all cases of severe primary dysmenorrhoea can be cured by sympathectomy, but this operation should not be done until all conservative measures have proved futile. Finally, in cases subjected to a number of laparotomies without relief of pain pelvic sympathectomy will yield spectacular results.

Intraspinal (subarachnoid) injection of alcohol is another means of obtaining relief from excruciating pelvic pain. This procedure is much simpler than pelvic sympathectomy and does not even require treatment in hospital. Furthermore, the percentage of patients with uterine carcinoma who obtain relief is higher than with pelvic sympathectomy. Nevertheless, because this procedure may injure the spinal cord it should not be used for any individual except one with cancer.

## RELIEF OF PAIN IN INTRACTABLE CANCER OF THE PELVIS

BY

MEAVE KENNY, M.D., F.R.C.O.G.

University Reader in Obstetrics and Gynaecology, Postgraduate Medical School of London

Cancer of the pelvic organs—intractable by surgery or radiation, or recurrent after such measures—may condemn a man or woman to unnumbered hours of pain before death. Such people may die hard, being often in the prime of life and general health, and capable of service and happiness in their remaining days if relief from pain could be given them without impairing their mental and bodily functions. Opiates in increasing doses, neurectomies, and intrathecal injection of alcohol often increase the nursing responsibilities and make the last days of the sufferer odious to himself and to his nearest.

The treatment of such patients is surely a part of the treatment of cancer, yet among the great number of papers devoted each year to the subject of cancer of the urogenital tract alone the means of relief in hopeless cases is barely mentioned, and the average practitioner, who must shoulder their care, may have the impression that skilled surgical procedures, sometimes unavailable or impracticable, offer the greatest measure of help.

Here is described a means of relief which has borne some careful trial and which is recommended for effect and simplicity and because it can be used at need again and again until the end. This is the method of caudal analgesia.

It has seemed right to me to describe it in some detail, for this paper is addressed particularly to the general practi-

tioner and to those in charge of the chronic sick in home and infirmaries who may not be familiar with the technique

## The Method

The apparatus consists of: Surgical spirit or "dettol" cream for cleaning the skin, and tincture of iodine or other colour antiseptic for surface-marking; 1 5-ml. Record syringe; Record-fitting needle, 8/10×1½ in. (3.75 cm.); 2 10-ml. Record syringes; 1 Record-fitting needle, 15/10×3 in. (7.5 cm.), bore: procaine, 1.5% solution; "proctocaine," 40–60 ml. (procaine 1.5% w/v, butyl p-aminobenzoate 6% w/v, with benzyl alcohol in arachis oil).

The patient is placed across the bed in the left lateral position and the buttocks and sacrococcygeal area are cleansed and disinfected. The caudal opening of the sacral canal is identified (usually with ease, and more easily in men than in parous women, who may have had the coccyx displaced in childbirth and marked with a dab of iodine. A subcutaneous wheal raised at this point with the 1½-in. needle attached to the 5-ml. syringe charged with the procaine 1.5% solution, and through this the tissues down to the tough fibrous membrane closing the sacral canal are infiltrated. The needle is then withdrawn, and after two minutes the stout 3-in. needle is made to follow the track of the first needle, at an angle of 45 degrees to the skin until the fibrous membrane is encountered and pierced; the needle is depressed to an angle of 15 degrees and pushed steadily on until the operator is sure that about 1 in. (2.5 cm.) of its length is lying freely movable within the space of the sacral canal. The needle, which after withdrawal of the piston reveals neither blood nor spinal fluid, is then attached to the 5-ml. syringe recharged with procaine and the whole is injected boldly. The beginner will know if he is posterior to the sacrum by the appearance of a subcutaneous swelling, anterior—between rectum and sacrum—by an exploring finger in the anus. Convinced of his correct position by the free flow of the anaesthetic and by his observations, the operator detaches the syringe and replaces it with one of the 10-ml. syringe charged with warmed proctocaine. He then steadily injects the proctocaine to an amount varying with the skeletal size of the patient—usually 40 to 60 ml.—taking some ten minutes to do so, meanwhile testing every minute the levels of cutaneous anaesthesia to pin-prick of the perineum, thighs, buttocks, abdominal wall, and asking the patient to say when relief of his pain takes place, although it is usually pleasantly evident from the gradual relaxation of attitude and expression. When this becomes known, or if the level of skin anaesthesia rises to nipp level, the injection is stopped and the syringe detached.

Sometimes complete relief is obtained at once, but sometimes it comes only when the patient is eased on to his right side, is made to stand up, or lies on his back with the foot of the bed raised for a few minutes. Sometimes the greatest relief comes after a period of lying on the back with the buttocks raised on a pillow, so as to allow the oily solution to seep higher, although it is better to inject 6 to 10 ml. more through the still present needle and obtain effect at once. For in this, as in all cases of long-continued and severe pain, the habit of suffering is best broken swiftly and convincingly. Most often the sufferer is at once so eased of the superflux of his pain that he endures the rest with fortitude and having co-operated to obtain the result—knowing that by such simple means relief can be obtained again if necessary and that probably the pain will come no more—a pride in living returns.

In such circumstances I have seen an old dancer brought into the clinic in a wheeled chair, with both thighs drawn up on to the abdomen in painful spasm due to cancerous infiltration of the psoas muscles, and then after the injection straighten herself off the couch, at first gingerly, and then smilingly assume several poses of the ballet before the watching delighted class of students and nurses.

I and my assistants have so treated 17 patients with cancer of the uterus, bladder, prostate, and vagina. Of these one—a man aged 58 with prostatic cancer, who was

incapacitated with pain for three months—was able to return to his work as a milk-roundsman for the rest of his life (nearly seven months) and die easily of a haemorrhage. He needed only one injection of 50 ml. of proctocaine. The ballet dancer, aged 46, died quietly of cardiac secondaries from cancer of the cervix uteri after two injections of 40 ml. of proctocaine, the second injection being fortified with 1 ml. of absolute alcohol, nine weeks after her first visit to us. The duration of relief with one to three injections varied in 11 others from three weeks to four months; in all but four this marked their natural term. The four developed painful secondaries in other regions, and one of them had a neurectomy for this reason.

One other, a tough Welsh miner of wonderful physique with extensive invasion of the abdominal wall by a cancer of the bladder, died apparently from exhaustion and haemorrhage under thiopentone anaesthesia, given before attempting the caudal injection, as in no other way could the unfortunate man bear being turned on his side. This was our only disaster. Necropsy was refused, so that oil embolism could not be ruled out as the immediate cause of the sudden death shortly after the caudal injection was begun. He had suffered hideous pain for some weeks before.

Two women with pelvic secondaries from uterine cancer had apparently complete relief for a few days after injection, but on return of symptoms failed to be relieved by further injection. In one, intestinal obstruction by secondaries was proved at necropsy; in the other, massive abdominal and pulmonary secondaries proved fatal under opiates.

One man with prostatic cancer was not relieved at all; radiography had revealed spinal metastases, and he was kept under morphine for the few weeks left.

I have not observed or been told of any urinary or faecal incompetence following caudal injection of proctocaine, with or without added alcohol, in any of the patients treated.

I wish to thank Drs. Constance Wood and Lilian Walter, of the Medical Research Council Radium Centre in the British Postgraduate Medical School, for referring to me patients in their wards; my colleague in the Department of Obstetrics, Dr. Hilda Roberts, who assisted me with many of the injections; and my colleagues of the Department of Surgery for asking me to treat most of the male patients mentioned in this paper.

"Diet in Pregnancy" was the subject chosen by Prof. W. C. W. Nixon for his lecture at the Royal Institute of Public Health and Hygiene on Nov. 12. Sir Jack Drummond, F.R.S., was in the chair. In a community where diet was faulty or restricted, said Prof. Nixon, the mother, expectant and nursing, and children suffered first. Did the pregnant woman differ from the rest of the community regarding her dietetic requirements? Everyone agreed that in pregnancy those were increased. Natural foodstuffs were far better than synthetic tablets. It may be argued that, with the present food restrictions, it was impossible to attain anything like the ideal diet for a pregnant woman. However, a remarkably good diet had been planned by, for example, a Scotch hospital. The nutrients were obtained only from natural foods, but the margarine was fortified with vitamins A and D, and full use made of the additional rations available for pregnant women. Recent reports from America showed the benefit that resulted from increasing the protein intake during pregnancy. It had been found that the incidence of toxæmia in pregnancy was twice as great in one group of pregnant women, where protein intake was 60-70 g. daily, as compared with a similar group whose protein intake ranged from 110 to 120 g. daily. The health of a nation could be gauged by the vital statistics of pregnancy and infancy. He would like to quote from the Report of the Chief Medical Officer of the Ministry of Health on the state of the public health during the six years of war (1939-45): "The national provision of milk and vitamin supplements . . . together with rationing and the greatly improved quality of the national loaf, has contributed to the gradual decline in the maternal, neonatal, and infant mortality and stillbirth rates." Women of younger years were only too willing to be educated in health matters when these were explained simply. It was in this way that the mothers of our country would be guided to contribute to one of the greatest measures in public health—proper nutrition.

## STAPHYLOCOCCAL INFECTION DUE TO PENICILLIN-RESISTANT STRAINS

BY

MARY BARBER, M.D.

(From the Department of Bacteriology, British Postgraduate Medical School, Hammersmith Hospital)

The incidence of strains of *Staphylococcus pyogenes* that are grossly resistant to penicillin is clearly increasing rapidly. The rate of increase in this hospital at present is so rapid as to be somewhat alarming. In a previous study (Barber, 1947) all cultures of *Staph. pyogenes* occurring in the routine bacteriological laboratory were tested for penicillin sensitivity; out of a series of 200 patients yielding cultures of *Staph. pyogenes* penicillin-resistant strains were isolated from 25 (12.5%). Since then cultures have been tested for their reaction to penicillin only if they came from an infected lesion. In analysing a series of 100 patients with staphylococcal infection between February and June, 1947, it was found that as many as 38 yielded penicillin-resistant strains. Table I gives a comparison of the two series. In

TABLE I.—Analysis of Patients Yielding *Staph. Pyogenes*

	From Whole Hospital			From Unit X		
	Total	Penicillin-resistant		Total	Penicillin-resistant	
		No.	%		No.	%
Series 1. Apr.-Nov., 1946:						
All strains	200	25	12.5	80	13	16.25
Strains from infected lesions	99	14	14.1	14	4	28.55
Series 2. Feb.-June, 1947	100	38	38	25	14	56

order to make a fair comparison, in Series 1 the figures for staphylococci isolated from cases of infection are given separately as well as figures for all specimens tested. In view of the high incidence of resistant strains in Series 2 it was thought worth while to record this second series, together with some observations on the source of penicillin-resistant strains and the best method for their detection.

### Analysis of Resistant Strains

The degree of resistance was in all 38 cases gross (see Fig. 1), and all, except one strain which was not tested, were shown to produce penicillinase; 36 of the strains were found to have a sensitivity to streptomycin approximately equal to that of the Oxford staphylococcus; one strain was not tested against streptomycin; and one strain, which came from a patient with tuberculous meningitis who was being treated with streptomycin was resistant to it.

FIG. 1.—a, d, f, and g are penicillin-sensitive and b and c penicillin-resistant strains of *Staph. pyogenes*; c is a culture of *Salm. typhi*.

Table II analyses the patients according to type of infection. The case of septicaemia arose from an abscess in the buttock following injections for a refractory anaemia, and the outcome was fatal. The case of osteomyelitis was a chronic infection and gave a mixed growth of *Pseudomonas pyocyanea* and penicillin-resistant *Staph. pyogenes*.

TABLE II.—Type of Infection in 38 Patients Yielding Penicillin-resistant Strains of *Staph. Pyogenes*

Septicaemia .. .. .	1	Otitis media .. .. .	4
Extradural abscess .. .. .	1	Infected operation wounds .. .. .	3
Osteomyelitis .. .. .	1	Puerperal infection (local) .. .. .	2
Respiratory tract infections .. .. .	8	Superficial lesions .. .. .	5
Neonatal infections .. .. .	12	Tuberculous sinus .. .. .	1

The respiratory infections included bronchopneumonia, infected carcinoma of the lung, actinomycosis, bronchitis, and tracheitis. Several of these cases showed an interesting change in bacterial flora of the sputum during the course of penicillin treatment and will be referred to later. The neonatal infections consisted of four cases of ophthalmia neonatorum, two abscesses, one discharging ear, one buccal

originally sensitive staphylococci which have acquired resistance to penicillin by contact with it but are natural resistant strains which survive by a simple process of selection in penicillin-treated infections. That such changes in bacterial flora do take place during the course of penicillin treatment is becoming increasingly clear, and is well illustrated by five of the cases of lung infection in this series.

Patient R. C., a case of carcinoma of the lung, had a sputum heavily infected with *Staph. pyogenes* shortly after admission to hospital; 30 colonies picked from the original culture plate were as sensitive to penicillin as the Oxford staphylococci but when a mixed emulsion from this plate was replated on to a penicillin ditch-plate it was seen that a number of penicilli

FIG. 2.—Emulsions of bacteria in broth plated out on penicillin ditch-plates with a central streak of the Oxford staphylococcus. (a) Pure culture of a penicillin-sensitive *Staph. pyogenes*. (b) Pure culture of a penicillin-resistant *Staph. pyogenes*. (c) One part penicillin-resistant to 10,000 parts penicillin-sensitive *Staph. pyogenes*. (d) One part penicillin-resistant to 5,000 parts penicillin-sensitive *Staph. pyogenes*. (e) One part penicillin-resistant to 250 parts penicillin-sensitive *Staph. pyogenes*. (f) Emulsion from sputum plate culture of patient R. C. replated on to penicillin ditch-plate, showing that approximately 1 in 250 of the staphylococci were penicillin-resistant.

ulcer, and four superficial lesions. In most of the 38 cases *Staph. pyogenes* was the only, or at least the predominant, organism isolated; from 10 patients both penicillin-sensitive and penicillin-resistant strains of *Staph. pyogenes* were isolated from the same specimen.

#### Source of Penicillin-resistant Strains

It is obvious that the main cause for this increase in penicillin-resistant strains of *Staph. pyogenes* is the widespread use of penicillin, although a patient yielding such an organism may not himself have ever had any. In the present series 28 of the 38 patients with penicillin-resistant staphylococci had had a fair amount of penicillin before the specimens were taken, two had had a few doses, and eight had had none. For the reasons stated in the previous paper (Barber, 1947) it is my opinion that these strains are not

resistant organisms were present (Fig. 2f). Twelve days later when the patient had had 2.8 million units of penicillin, the sputum again yielded a heavy growth of *Staph. pyogenes*, but 30 colonies tested were all found to be penicillin-resistant. Subcultures from three sensitive and three resistant colonies (one from the first sputum and two from the second) were typed by Dr. Allison and Dr. Hobbs; all three sensitive cultures were phage type 29/52 and serological type 1, whereas all three resistant cultures were serological type III and were not typable by the phage method.

Patients N. H., M. H., and M. S. all had bronchopneumonia. From each the first sputum tested contained no colonies of *Staph. pyogenes*. After 15.9, 11, and 4.8 million units of penicillin respectively, the sputum of all three patients yielded a heavy growth of *Staph. pyogenes*; in patients N. H. and M. H. all the colonies tested were penicillin-resistant, but in patient M. S., who had had the least penicillin, nine colonies were found to be resistant and one sensitive to penicillin.

Patient R. W. had actinomycosis of the lung with an empyema. On admission a heavy and pure growth of *actinomyces* was isolated, but after 21 million units of penicillin this organism disappeared and pus from the empyema gave a pure growth of penicillin-resistant *Staph. pyogenes*.

The question arises, Where do these penicillin-resistant organisms come from? In some cases—as, for example, Patient R. C.—they are clearly present in the original lesion overgrown by sensitive strains until penicillin treatment gives them a clear field by getting rid of the latter. Hospital infection with *Staph. pyogenes* is, however, fairly common, and, as Harley *et al.* (1946) have shown, penicillin-resistant staphylococci occur far more often in patients who have been in hospital some time than in new admissions. Any hospital using large quantities of penicillin (and what hospital is not nowadays?) bacteria resistant to its action are probably increasing at the expense of those that are sensitive, and it seems not impossible that in time the resistant organisms will be the sole survivors. That a penicillin-resistant strain of *Staph. pyogenes* once it has got footing in the hospital may spread from patient to patient is well illustrated by a series of cases occurring in a particular unit of this hospital, referred to hereafter as "Unit X." Throughout the two investigations the percentage of penicillin-resistant strains was higher in Unit X than elsewhere in the hospital (see Table I); five resistant and two sensitive cultures isolated from this unit during a single month were therefore sent to Dr. Allison and Dr. Hobbs for typing. The results are shown in Table III. It will be

TABLE III.—Strains of *Staph. Pyogenes* Isolated from Unit X

Source	Date of Isolation	Reaction to Penicillin	Phage Reaction	Serological Reaction
Raw milk .. ..	9/10/46	Resistant	6/47	III
" .. ..	18/10/46	"	6/47	III
Scarean wound ..	27/10/46	"	6/47	III

Raw milk .. ..	20/10/46	Sensitive	Nil	I
" .. ..	20/10/46	"	Nil	I

seen that all five resistant strains were of the same type and that the sensitive organisms were of the same type as each other but different from that of the resistant bacteria.

#### Detection of Penicillin-resistant Strains

From observations made during this investigation it seems that the best method for the detection of penicillin-resistant bacteria in specimens sent to the laboratory is to plate out the infected material direct on to a penicillin ditch-plate, using a concentration of about 10 units of penicillin per ml. of agar in the ditch (Figs. 1 and 2). Although this method is in fact used in many routine bacteriological laboratories the following two reasons for its superiority over other methods are not generally appreciated.

1. Most methods described for determining the penicillin sensitivity of bacteria ignore the size of inoculum used, as it is claimed that within wide limits this made little or no difference to the results (Fleming, 1942; Abraham *et al.*, 1941). As shown by Luria (1946) and Barber (1947), this is far from the case with penicillinase-producing bacteria. With such organisms a small inoculum may appear to be fairly sensitive to penicillin, whereas a large inoculum will grow in a concentration of 100 or more units per ml. This is well illustrated by plating out pure cultures of penicillin-sensitive and penicillin-resistant staphylococci on penicillin ditch-plates. Fig. 2a shows sensitive culture which gives a fairly straight line of inhibition. Fig. 2b, on the other hand, shows a pure culture of penicillin-resistant staphylococci, and it will be seen that where the inoculum is heavy the organisms have grown right across the penicillin agar, but as the number of bacteria gets smaller an increasing amount of inhibition of growth occurs. Such a picture is seen only with penicillinase-producing organisms.

A bacterium, such as *Salmonella typhi*, which is resistant to penicillin but does not destroy it, when plated on a penicillin ditch-plate produces a straight line of growth which usually reaches the penicillin agar when a concentration of 10 units per ml. is used. Thus by this method some information on both the degree and the type of resistance is obtainable.

2. Swabs from many staphylococcal lesions contain a mixture of sensitive and resistant strains. In some cases before any penicillin treatment has been started the number of resistant bacteria is very small, as illustrated by Case R. C., and they may be missed by simply testing a number of individual colonies. If, however, the material is plated direct on to a penicillin ditch-plate, as few as 1 resistant to 10,000 sensitive bacteria may be detected (Fig. 2c), and by comparison with known mixtures some idea of the proportion of resistant to sensitive strains may be determined. Thus the bacteria in the sputum of R. C. when replated (Fig. 2f) showed a similar picture to a mixture of 1 part resistant to 250 parts sensitive staphylococci (Fig. 2e).

#### Summary

In studying strains of *Staph. pyogenes* isolated from 100 cases of staphylococcal infection 38 patients were found to have penicillin-resistant strains; 10 patients had a mixture of penicillin-resistant and penicillin-sensitive staphylococci.

The source of these strains and the best method for their detection are discussed.

My thanks are due to Drs. Allison and Hobbs for typing, and to Drs. Anderson and Fullerton for the primary isolation of many strains.

## ALLERGY TO PENICILLIN WITH SYMPTOMS OF SERUM SICKNESS

BY

A. G. WILKINSON, M.D.

AND

K. ZINNEMANN, M.D.

Lecturer in Bacteriology, School of Medicine, Leeds

Toxic side-reactions and allergic symptoms following the administration of penicillin have lately attracted a good deal of attention in the U.S.A. Two papers published there dealing with this subject (Morginson, 1946; Holden, 1947) include a fairly comprehensive review of the literature. In this country Suchecki (1946) and Willcox (1946) described series of cases, and the former reviewed some of the literature. A number of single case reports have also been published in both countries, and these emphasize the variety of symptoms which may occur. One of the severest syndromes is a reaction similar to serum sickness, with some of the symptoms of anaphylactic shock. Feinberg (1944) and Rostenberg and Welch (1945), investigating the origin of this hypersensitiveness, suggest that, at least in the U.S.A., sensitization is brought about by ingestion or inhalation of *Penicillium* spores. These produce subclinical infections in approximately 5 to 6% of persons of allergic diathesis. No such data are available for this country. Feinberg's skin tests suggest that some batches of penicillin are tolerated better than others by allergic persons.

The following account of a case with severe and at times alarming symptoms is interesting for two reasons: (1) the same symptoms occurred twice, with increased severity on

the second occasion; and (2) the fact that intracutaneous sensitivity tests made it reasonably certain that the impurities in the penicillin preparations were implicated more than the penicillin in causing the symptoms.

### Case History

On the night of July 24, 1945, a female patient aged 34, three weeks post partum, developed a sudden rigor. There was a painful induration and redness of the right lower quadrant of the right breast. During the next 24 hours her temperature varied between 102° and 103° F. (38.9° and 39.4° C.). From July 25 to 27 16,000 units of sodium penicillin were administered intramuscularly every three hours, together with sulphathiazole (2 g. stat., followed by 1 g. four-hourly for three days). Her temperature returned to normal within 48 hours and the local breast lesion cleared up completely within 72 hours.

Two weeks later urticarial weals appeared on the scalp. During the next five or six days there developed a massive urticaria and angioneurotic oedema of the face, trunk, and limbs, with severe pruritus. There was no rise in temperature. The patient complained of a feeling of tightness in the chest; she was very pale; the pulse was thin, with a rate of 80 to 90 a minute, her normal rate being about 60. Sitting up caused severe vertigo. Adrenaline and ephedrine were administered, but did not relieve the urticaria or the pruritus, and about 12 hours later paroxysms of tachycardia developed, with a pulse rate of 120 and upwards. Without further specific treatment the condition cleared up completely within five to six days. On account of the long interval between penicillin therapy and the onset of the allergic symptoms, penicillin was not suspected as a possible causative agent.

On Feb. 22, 1946, the patient complained of a red painful swelling in her right thumb. Within the next 12 hours the swelling increased rapidly and her temperature rose to 101.5° F. (38.6° C.). A course of 16,000 units of sodium penicillin intramuscularly at three-hourly intervals, together with sulphathiazole (2 g. stat., followed by 1 g. four-hourly), was started the next day. The first injection of penicillin into the gluteus maximus was extremely painful and the patient felt collapsed. The pulse volume was fairly good, with a frequency of 62 a minute. Recovery followed within half an hour. The penicillin injections were continued for five days without further untoward effects. The local and general condition improved rapidly, apart from a feeling of tightness in the chest on the fourth day of treatment, and after seven days the patient was quite well.

On March 5, 1946, 12 days after the start of penicillin treatment, oedema of the eyelids was noticed, and the patient complained of a general feeling of weakness. In the evening she was in a state nearing collapse, with slight rigors. The temperature was 99.6° F. (37.6° C.) and the pulse was thin and rapid. Patches of urticaria appeared on the arms and back. The next day there was a generalized giant urticaria with angioneurotic oedema. The patient was somnolent and very difficult to rouse, took no food or drink, and passed no urine during the next 24 hours. The pulse rate was 80-90.

The drowsiness persisted on the following day, and the patient had pains in the wrists and feet, which were swollen. The next day she complained of soreness and tightness of the throat, and on inspection an oedema of the fauces, and of the uvula in particular, was noticed. This passed off within 12 hours. On the fourth day the general condition had begun to improve. The oedema of the face was less, but oedema of hands and feet was still pronounced. The patient now began to take food, and there was rapid improvement during the next few days. On the ninth day she was normal except for a general feeling of weakness, which persisted about two weeks.

Eight weeks after the allergic symptoms had subsided skin-sensitivity tests were carried out to determine whether penicillin or sulphathiazole had caused the severe reaction. Patch tests and intradermal injections were the methods employed. All patch tests with solutions of penicillin (20,000 units per ml.), "sulphathiazole," and physiological saline were negative.

In the intracutaneous tests the following solutions were used: (1) a commercial preparation of impure penicillin (yellow); (2) a commercial preparation of pure crystalline (white) penicillin—both in a concentration of 16,000 units per ml.; and (3)

the disodium cinnamylidene dibisulphite derivative of sulphathiazole. The latter, known under the trade name of "sulthiazole," is in the form of a 45% solution, and was diluted one in five with sterile distilled water in order to obtain an isotonic solution. Quantities of 0.02 ml. of these solutions and of physiological saline as a control were injected intradermally into the upper arms, and the following reactions at the site of the injections were observed: penicillin (yellow), ++; penicillin (white), (+); sulphathiazole, 0; 0.85% sodium chloride, 0.

The marked reaction to yellow impure penicillin strongly suggests that the impurities played the main part in producing the severe allergic condition, though the very weak reaction to pure crystalline penicillin also seems to implicate the penicillin as a rather mild allergen. The tests excluded sulphathiazole as a possible allergen.

### Discussion

Although there are statements in the literature that renewed penicillin therapy does not necessarily produce a repetition of allergic symptoms, this case shows that the severity of the reactions may be increased considerably, and there is a possibility that each subsequent attack may tend to increase the degree of sensitivity still further. It is well to remember that there may be a considerable lag period between the administration of penicillin and the beginning of allergic manifestations. Occurrences as the one described should tend to discourage the use of penicillin in trivial infections which would clear up with the traditional conservative methods.

Willcox (1946) described the use of "benadryl" in cases with mild allergic symptoms, particularly those of urticaria after penicillin therapy. This was not freely available at the time. It remains to be seen whether severer symptoms such as the ones described in this case can be controlled effectively by antihistamine preparations.

We are indebted to Messrs. May and Baker Ltd. for a sample of "sulthiazole" and information regarding isotonic solution of the preparation; and to the Glaxo Laboratories Ltd. for a sample of white crystalline penicillin.

## CHRONIC BATTLE NEUROSIS TREATED WITH LEUCOTOMY

BY

WILLIAM SARGANT, M.B., M.R.C.P., D.P.M.

AND

C. M. STEWART, M.R.C.S., L.R.C.P.

(From the Sutton Emergency Hospital Neuropsychiatric Unit)

From the time of Dunkirk onwards various ways of using physical methods in the treatment of acute and chronic battle neuroses have been a subject of research in this unit. Sleep treatment and barbiturate abreaction (Sargant and Slater, 1940), "front-line" sedation (Sargant, 1941, 1942), and modified insulin treatment (Sargant and Craske, 1941) have now found a generally recognized place in different stages of the rehabilitation of those breaking down under the battle stress. The value of these treatments emphasizes the physiological aspects of many neurotic conditions, but so far there has been no report of the use of leucotomy in this particular group. It is the purpose of this paper to report a case in which great improvement resulted after this brain operation, one of the effects of which appears to be to reduce self-perpetuating tension within the nervous system.

The possible application of leucotomy to the rehabilitation of the chronic battle casualty has been held up by a natural reluctance to employ it except in the final stages of psychiatric treatment. Since 1941, however, the possibilities of leucotomy in helping various types of chronic civilian neuroses have been carefully studied. Over thirty patients have now had the operation done, either at this hospital or at the Atkinson Morley Neurosurgical Unit by Mr. W. McKissock, or at the West End Hospital for Nervous Diseases by Mr. G. Knight. Certain criteria which may help to distinguish the suitable from the unsuitable patient have gradually emerged and have finally enabled this case of chronic battle neurosis to be operated upon with a reasonable probability of success.

### Case Report

The patient, a man aged 36, was admitted to the Sutton Emergency Hospital on Aug. 31, 1946. There was no history of serious neurotic or psychotic illness in the family. He was one of eight children, all considered stable, but the patient had been a more sensitive child than the rest. He had done reasonably well at school, was keen in sports, had completed a full seven-years apprenticeship as a printer, and was in regular work at this trade and in a munitions factory until he volunteered for the Army from a reserved occupation in 1942. His wife described him as happy, good-tempered, hard-working, and certainly not nervous, though still sensitive to criticism by others. He was perhaps over-particular about his personal appearance and habits, but conscientious about his work and interested in his home. Until the illness it had been a happy and successful marriage.

After preliminary training in amphibious warfare he had landed on the beach-head with the first batch of tanks on D Day. From then onwards he was in the heavy tank fighting in France, Belgium, Holland, and Germany. Many of his friends were gradually either killed or burnt to death in their tanks and the patient increasingly expected each day's fighting to be his last. "I had made up my mind that probably I was going to be killed and could not get out of it." During the investigation of possible traumatic incidents that might have caused his symptoms so many of them were found in his fighting experiences that they proved impossible to evaluate or disentangle. He managed to escape twice after his tank had received direct hits, and for some months he met battle stresses with a mounting tension and aggression but no breakdown, though he first started to feel pains in his legs at this time. Near Cologne he had received the second direct hit on his tank, which was blown open. Somehow he escaped in a dazed state and crawled to safety, with a small wound and fractured bone in his foot. He was sent back to England for treatment. When seen by his wife in hospital in November, 1944, he had obviously changed as a result of his battle experiences. He gradually became worse nervously in hospital, and was unable to face a return to duty some four months later when his foot was better, and was finally admitted to a military neurosis centre. He was discharged from the Army after some months' further treatment and was given a few shillings pension a week.

On return to civilian life he tried to resume work with his old firm as a printing-machine operator in August, 1945. He did so, but with increasingly frequent periods off work through pains in the legs, lethargy, headaches, irritability, and poor sleep. He became very sensitive to all criticism and irritable with his wife. His finances became desperate, and articles from the home had to be sold, which further increased his anxiety. When admitted to Sutton Emergency Hospital he was irritable, and begged for relief of his symptoms. He had severe headaches, fatigue, depression, and nagging pains in his legs. He was afraid of himself, was continually worrying about his war experiences, and felt that people criticized him because of his behaviour. On examination he was mildly depressed, was unable to settle at reading or any other occupation, was preoccupied with severe pain in his legs for which no organic cause could be found, was disgruntled at the treatment he had received with regard to his pension, and was worried that he would never get better. He

often expressed the opinion that it would have been luckier for him to have died in battle with his friends than to live on as he was. Schizophrenic symptoms were not present, but he was mildly paranoid, hypochondriacal, and tense under a superficial display of shallow affect. Home life, previously very happy, had been near breaking-point—despite an understanding, normal, and very helpful wife—because of his irritability, sudden tendency to flare up, and perpetual preoccupation with his neurotic symptoms. He was the same in hospital—continually demanding relief of his many pains, varying in attitude between superficial appreciation and sullen criticism of all efforts to help him. He sat in the ward most of the day watching the activities of others, but unable to occupy himself at anything. Apart from compulsive rumination there were no motor acts present of an obsessional kind. His intelligence was average and his memory good.

During nine months of very intensive treatment in hospital prior to leucotomy the patient had had many hours of psychotherapy, but always seemed unable to gain insight into his symptoms. In a dozen sessions of therapeutic exploration of battle experiences, using intravenous barbiturates or ether, many traumatic incidents were gone over, accompanied by a release of great emotion, but with little effect except to relieve some of his headache. Large doses of barbiturate were necessary to help his symptoms of tension, and he gained the greatest relief when insulin sopor was given twice a day, producing a more calm, relaxed, and friendly state but no permanent change. When tension could be relieved, however, he lost the apparent shallowness of his affect, was genuinely appreciative of help, and the pains in his legs were less evident. Because the presenting symptoms might be masking an atypical depression electric convulsion treatment was also tried alone, and then combined with insulin sopor; but it worsened rather than improved his condition and had to be stopped. A final attempt was made to abreact repressed traumatic material as he came out of insulin comas specially given for the purpose, but again with no lasting success. On several occasions he was sent home for periods of leave to see if he was any better in his home environment as a further check on treatment. Before operation, and despite all the treatment given, his condition was practically unchanged except for some relief of his headaches in the frontal region. He was still repeatedly demanding relief for his various pains, and felt an increased hopelessness of ever getting better.

Before operation he was submitted to Dr. L. Minski for an independent psychiatric opinion. The comment was as follows: "My impression of this man is that he is a hysteric—he is histrionic, talks glibly of his pains, etc., and is apathetic. He is not really depressed, but is self-centred and shallow. On talking of his pension he becomes irritable and fidgety, and my impression is that he is largely a compensation neurosis. Quite frankly, I agree that psychological and ordinary physical methods of treatment are not likely to help him, but I don't know what effect leucotomy will have on him. I can find no antisocial traits in his pre-neurotic personality."

With the wife's and the patient's consent, both having been warned of the risks entailed, leucotomy was performed on June 9, 1947, by Mr. W. McKissock. There was little post-operative confusion and the patient was up and about in six days. He was, however, lethargic and careless about the ward immediately after the operation, but this rapidly improved. He reported an immediate lessening of his symptoms, and within six weeks was asking to return to work. His whole attitude had changed to one of pleasant co-operation, friendliness, and sociability with other patients and the doctors. The pains in his legs were now rarely present and did not bother him. Tension was absent. He was sent home to spend three weeks with his wife before starting work. The patient and his wife were both subjected to an intensive questioning at the end of the three-weeks trial period. The wife insisted that he was now to all intents and purposes like he had been before his illness. He had again become kind, considerate, cheerful, good-tempered, and less sensitive. No mention had been made of the pains in his legs; his tension and self-pity had gone. He was still lacking in energy, but anxious to be back at work, and rather inclined to switch his interest of the moment too quickly while waiting.

The patient's examination bore out these favourable reports, as did his whole attitude and manner. He said he felt well again, looked it, and was anxious for permission to start work immediately. He now felt quite confident about returning to his job as a printer, which had been kept open for him. There was no euphoria or elation in his attitude but a reasonable appreciation of his past illness, what had been done for him, and what he should try to do in future to keep well. At the time of writing he is back at his old job, and both his work and home life are reported as satisfactory, with an increasing restoration of his old energy. In the face of repeated questioning his wife maintains that except for his energy "he is now as I first knew him."

Intelligence has shown slight drops of 116 to 110 in Wechsler and 48 to 45 in matrix testing. Some of this small drop may be due to reduced capacity for sustained attention and transient amnesic effects of the operation, the scores in the Wechsler being reduced only in information and vocabulary subtesting. Dr. M. Desai was also asked to do Rorschach tests before and after operation, with no reference to the clinical notes or history of the patient. He made the following summary of the changes observed in tests two days before and seven weeks after the operation. "The pre-leucotomy record indicated a rigid, uncompromising attitude, with hardly any regard for practical issues. In his second record there is a very marked swing towards normality, with willingness to compromise. The suspiciousness and projected hostility, the feelings of depression, insecurity, and unsureness which prevailed in his first record have disappeared. There is a reduction in the patient's tendency to get disorganized in the face of emotional stimuli. The uncontrolled emotionality which characterized his first record is very considerably reduced, and he shows in the second record an inclination towards more adapted emotional reactions. These changes seem to be due, however, not so much to an increase in control as to a reduction in sensitivity to external stimulations. Another aspect of the tendency is the patient's greater reliance, as shown by the tests, on his own inner resources than was the case before the operation. The general trend seems, therefore, to be towards a much more normal adaptation and a greater willingness to co-operate with his environment than that found in his first record."

### Discussion

The improvement of this patient has been among the most gratifying in the several thousand cases of war neurosis treated at Sutton in the past seven years. Relapse at a later date cannot be excluded, but, for various reasons connected with our follow-up of other patients, it is not considered probable. Those who have been ready to predict a gross deterioration in general personality, intelligence, or social behaviour whenever leucotomy is attempted may wish to reserve judgment on the opinion of the patient's wife and the doctors treating him that such gross changes were absent. But this has also not been an uncommon finding in our civilian neuroses selected for operation. The after-effects of brain operations and of cerebral trauma in general depend a lot on the previous personality of the patient. The better it is, and the better preserved it remains up to the time of operation, the fewer have been the undesirable after-effects with leucotomy. Another possible reason for the absence of marked deterioration in many of our patients may have been the attempt to modify, so far as is possible, the severity of the operation to suit the particular patient's symptoms. For the more extensive the brain damage inflicted the more such sequelae could be expected.

In a small group of chronic schizophrenics, treated along with the much larger number of neuroses and depressions, an added deterioration has, however, often followed the operation. Schizophrenic dilapidation and disordered brain function may become more clarified and obvious. Such a dilapidation is rarely seen in the better-preserved basic personalities. Decision to operate in a particular case has become somewhat easier recently by the finding that the more loath one has been in the past to carry out the

operation because of a continued preservation of general personality the better the quality of the eventual result. With its use in this type of patient it is of course necessary to have confidence, based on a long active experience in treatment, that as good a recovery by the other means now available is not to be expected.

This, however, helps to explain why some of our patients after leucotomy have been able to return to work as estate agents, clerks, housewives, calculating-machine operators, chefs, office managers, and the like after long illness and incapacity. But only one schizophrenic patient out of nine has done as well as these cases.

Certain temporary and permanent changes may be seen in all types of patient, such as lack of a former spontaneity and drive, some distractibility, a heightened irritability, lessened capacity to worry deeply about the misfortunes of others, and the easier acceptance of imposed standards of social behaviour and morals. But not even these are consistent findings. Hebb (1945) has reported a case in which both frontal lobes were removed for traumatic scarring causing epilepsy. No deterioration due to the removal could be detected in careful mental testing some years after the operation. Such changes have not always been easy to demonstrate clinically at an even earlier stage in some of our best results. And those present are often of academic and research interest rather than practical objections to the treatment, if cases are skilfully chosen for the operation from chronically suffering and severely incapacitated patients and operative interference is not too extensive.

It has already been pointed out that the present case of chronic battle neurosis was chosen as a result of previous observations and research on civilian neuroses. The reasons were as follows. The patient was considered incurable by other known methods after nine months of intensive study and active treatment in hospital and an illness of two and a half years' duration. The family history was good, and the patient's personality before illness showed none of the traits that suggest a more doubtful result with leucotomy, such as lack of basic drive, the presence of constitutional aggressiveness, marked general psychopathic qualities, severe manic-depressive mood swings, or tendencies to hysterical or schizoid withdrawal in the face of ordinary stresses. Favourable factors were a good previous social adjustment and drive, some over-meticulousness and sensitivity, a long period of proved stress well borne before final breakdown, and the presence during the whole illness of severe tension and rumination. This tension, seemingly aroused in the first place by battle experience, appeared to have finally become self-perpetuating in the nervous system, localized in intolerable hypochondriacal preoccupations, and superficially masked by hysterical, demanding, and paranoid attitudes without real insight. An important observation was that drugs which temporarily reduced tension, such as insulin and the barbiturates, helped the patient to become better integrated and to gain temporary insight and relief of symptoms. His condition was worsened by treatments of increased tension, such as convulsion therapy and wrongly directed forms of psychotherapy. Another important point was that both his home and his old job were still waiting for the patient if he recovered: the results of any treatment are often nullified by its delay till it is too late to remedy the social consequences of prolonged mental illness. There also seemed to be no real motivation to a continuance of illness if disabling symptoms could be abolished and working capacity and self-esteem restored. Such cases may be the exception rather than the rule in the average run of chronic war neuroses, but they are certainly to be found in all sections of the community and often struggling after outside ordinary psychiatric hospitals.

One further reason for reporting the case should be mentioned. The patient's wife became very alarmed, as have other relatives recently, when the operation was first suggested. This was in part because of her general practitioner's fears about leucotomy, which could have been derived from the correspondence column of the *British Medical Journal*. It is hoped, as a result of this report, that others who might benefit from this operation in the future will not lose their chance of being helped solely because of misinformed opinion or theoretical prejudice. A reasonable caution is bound to follow a careful study of actual results.

**Further Note.**—During proof correction the patient was again seen by one of us (C.M.S.) on November 4, 1947. He is working regularly with his old firm and his work on a printing machine is reported as satisfactory. He is still tired in the evenings and goes to bed earlier than usual. Frequency of micturition, present before the operation, is now increased. The wife reports a few minor bouts of irritability have occurred, which quickly pass; otherwise he remains thoughtful and considerate. He is again taking her to dances and resuming his old social contacts. He is normal sexually, his appetite is good, and he has gained weight.

Our thanks are due to Dr. L. Minski for providing the patients and the facilities for research at Sutton, and to colleagues at Sutton who have allowed us to examine leucotomy patients under their care.

## Medical Memoranda

### An Unusual Knee Injury

The unusual nature of the following case makes it worthy of record.

## CASE REPORT

A young airman was admitted to hospital complaining that he could not straighten his right knee. He said that he and a friend had been cycling along a main road, when their cycles had become locked so that they had both been thrown to the ground. On inspection there were sundry abrasions and an obvious lateral displacement of the patella. Routine radiographs (Figs. 1 and 2) showed, much to my surprise, that there was also present a long metallic foreign body with a chisel-like edge. In view of the fact that there was no evidence of splitting of the bone it was considered that the foreign body was most probably lying in the suprapatellar pouch, and that one of the abrasions must be a partially closed wound of entry.

Fig. 1.—Radiograph showing lateral view of foreign body.

At operation unexpected difficulty was experienced in reducing the patellar dislocation. The suprapatellar pouch was empty, and on extending the incision downward the foreign body was found. Only about 1/4 in. (0.64 cm.) was projecting from the inferior surface of the medial femoral condyle. It was firmly wedged and great force was required to pull it out, when it was revealed as being 1 1/2 in. (4.7 cm.) of the distal end of a 1 7/8-in. (0.3-cm.) screwdriver.

The patient made a good recovery. Radiographs taken five weeks after the operation showed no irregularity of the articular cartilage. He was given faradism and after six weeks was discharged to an R.A.F. hospital, with no free fluid, and with full extension and active flexion to 80 degrees. A fortnight later he returned to his unit on light duties.

## COMMENT

To explain the presence of the screwdriver I had to suppose that the piece had been lying in the road and had been knocked up into a vertical position by the falling cycle and had been in this position when the patient's knee fell on it. This rather

Fig. 2.—The foreign body from another aspect.

far-fetched theory held the field till the friend, who had been told of the findings, arrived with the rest of the screwdriver, which he had found in the tool-bag of his cycle in the condition shown in Fig. 3. Presumably the point of the screwdriver had

Fig. 3.—The broken screwdriver.

come out through the tool-bag flap in the fall, entered the femur, and got broken off, the rest of the screwdriver having fallen back into the tool-bag. The screwdriver was of poor quality, and the break was a fatigue fracture at the point of torsion.

The mechanism of the accident has been explained, but the absence of even a small split in the femur from an instrument which had penetrated a distance of 1 1/2 in. (3.8 cm.) and was so well adapted for shearing off the entire condyle is rather surprising. Perhaps the fact that the screwdriver entered slightly across the grain, coupled with the sudden breaking of its shaft, is the explanation.

I am indebted to Mr. Lloyd, radiographer to the hospital, for the x-ray prints; to Mr. Beven, of Messrs. Baker Perkins, Ltd., for the opinion on the screwdriver fracture, and to Mr. Guscott, of the same firm, for the photograph.

WM. MARSHALL, M.B., Ch.B.,  
Surgeon in charge of Service Fractures,  
Peterborough and District Memorial Hospital.

### Two Mongol Children in a Family

The rarity of the occurrence of two mongol children in the same family is sufficient warrant for putting any case on record. Brousseau in his monograph on mongolism quotes Goddard as stating that in an experience of 322 cases he had never met with more than one affected child in a family, nor had Schlapp, working among the mental defectives in New York. My own experience in more than 200 cases has been similar.

In the present instance both parents were strong and robust dalesfolk, and at the birth of the first child—a boy now 9 years of age—the father was 32, the mother 21. The second child, a girl, was born fourteen months later. There have been no subsequent pregnancies. Both babies were breast-fed, and both

show the typical physical and mental characteristics of mongolism but no other abnormalities, and the tongues are not fissured. Both have hyper-extensibility of the thumbs and both adopt the Buddha position when sitting on the floor. They show medium-grade imbecility and, as is always the case, are fond of music and keep themselves clean and tidy.

## COMMENTARY

The statement frequently made that the mongol most usually appears at the end of a large family when the parents are no longer young and the mother is approaching the climacteric requires modification, as may be seen from Table I, compiled from my own completed records and the figures given by Brousseau:

TABLE I.—Position of Mongol Child in Family

Order of Birth	Present Author (154 Cases) %	Brousseau (772 Cases) %
1st .. ..	23.3	25.2
2nd .. ..	23.3	19.8
3rd .. ..	10.4	13.5
4th .. ..	8.5	7.9
5th .. ..	8.5	6.5
6th .. ..	7.8	6.6
7th .. ..	7.8	6.7
8th .. ..	2.6	5.6
9th .. ..	2.6	5.3
10th .. ..	5.2	2.9

Thus 57% (58.5% according to Brousseau) of mongols occurred in the first three pregnancies, and in the greater number the parents appear to be perfectly normal physically and mentally. Benda found 124 mongols in 255 to belong to the first or second pregnancy. There is a progressive drop in successive pregnancies until the tenth is reached, when there is a small rise, which has little statistical value. Another very marked phenomenon is the rarity of mongolism in contradistinction to other forms of mental deficiency, and its comparative frequency amongst the more able and studious and the professional classes.

The age of the parents appears to play some part, the nature of which is obscure. Table II shows the percentages in two series of observations.

TABLE II.—Parents' Ages at Time of Birth of a Mongol Child

Age	Fathers %		Mothers %	
	Present Author	Brousseau	Present Author	Brousseau
Under 30 .. ..	20.2	19.2	18.1	27.1
31-35 .. ..	7.2	20.8	13.6	15.3
36-40 .. ..	23.2	21.6	30.1	26.3
41-50 .. ..	49.3	38.4	37.9	31.3
Total cases included	154	412	—	582

In his recent book, *Mongolism and Cretinism*, London, 1947, Benda states that 42% of the mothers were under 35, and quotes Beidleman as finding an identical percentage.

G. A. AUDEN, M.D., Ph.D., F.R.C.P.

### Angioneurotic Oedema as a Possible Sequel to Penicillin Administration

Angioneurotic oedema is rare enough to warrant attention, and the following case is of special interest in view of the possible aetiological connexion between the symptoms exhibited and the administration of penicillin.

## CASE REPORT

A young woman who had been very seriously ill with septicaemia in a London County Council general hospital was admitted here early in June, 1947, for rehabilitation. Her general condition, considering the severity of the illness, was surprisingly good—a fact we attributed to the large amount of penicillin she had received (15,840,000 units).

Progress was somewhat slow but, nevertheless, uninterrupted until on the evening of the twelfth day after admission she complained of severe pain in the right side of her neck. The temperature rose to 102°–103° F. (38.9°–39.4° C.), and a swelling began to develop below the styloid process. Penicillin in doses of 50,000 units four-

hourly was immediately started. By next day the swelling had greatly increased, and extended down the whole length of the sternomastoid muscle. Fluctuation was present and, although other cardinal symptoms of inflammation were absent, it was decided, in view of her previous history, to incise. A thorough exploration was made under thiopentone, but no pus was found. On the other hand the tissues were oedematous, especially the sternomastoid muscle, which was swollen to three times its normal size, and the subsequent dressings were wet with serum. Three days later everything had subsided and penicillin was discontinued. A tentative diagnosis of angioneurotic oedema, supported by a completely normal blood count, was made. The white cells numbered 6,000 per c.mm.

On the eighteenth day the temperature again rose abruptly to 103° F., and a painful fluctuating swelling developed over the supinator muscles below the right elbow. This rapidly increased in size to that of a large duck's egg. In view of the previous experience it was left severely alone, only ephedrine in 1/2-gr (32-mg.) doses three times a day being given. Three days later the swelling had disappeared and the temperature had returned to normal. The blood count was normal except for a slight reduction in platelet to 200,000 per c.mm.

A quiescent period followed, but on the nineteenth day from the resumption of penicillin therapy the temperature again rose and the patient developed a cough with frothy, watery sputum. Beyond slight catarrhal changes no physical signs could be detected, and x-ray examination revealed no abnormality. These symptoms again lasted for three days and were followed by acute abdominal pain in the right iliac fossa. This presented a difficult problem, as the maximum tenderness was exactly over McBurney's point, and with a temperature of 100° F. (37.8° C.) and a pulse of 98 there seemed little doubt but that the appendix, too, was oedematous. Fortunately for all concerned these symptoms subsided rapidly and the pain shifted to the left epigastric region and the left costal margin. The spleen was just palpable. Three days later the epigastric pain became intense and vomiting was frequent. Fluids were returned blood-stained, suggesting oedema and congestion of the gastric mucosa. Once again these symptoms persisted for three days.

During the whole of this period it was noted, especially by the nursing staff, that from time to time the patient became somewhat eccentric and irrational for short periods—symptoms which might point to small oedematous lesions in the brain. The condition now appeared to have burned itself out and there were no recurrences.

Other pathological investigations showed: a sedimentation rate increased to 13 mm. in the first hour, a clotting time slightly up at thirteen and a half minutes, and a bleeding time within normal limits at four minutes.

It will be noted that there were two separate attacks with an interval of ten days between. While it is impossible to dogmatize, the absence of any other aetiological factors and the fact that before each attack penicillin had been administered in large doses at least render it suspect as the causal factor. The patient had never suffered from such a condition before and there was nothing in her history even to suggest an allergic diathesis. Another curious feature was the site of election in each attack. During the first the skeletal musculature was singled out, while in the second the visceral and internal organs were involved.

J. OWEN REID, M.D.,

Medical Superintendent, Princess Mary's Hospital  
Margate.

Mr. L. Z. Cosin spoke on "Modern Methods in the Care of the Aged," at the Royal Institute of Public Health and Hygiene on Nov. 19. Mr. W. E. Tanner was in the chair. Mr. Cosin said that the aged population of Great Britain had risen from 2½ million (1901) to nearly 6½ million (1944) in about 40 years, while the Beveridge Report anticipated a further rise to 9½ million of pensionable age by 1971. The problem became more serious when they found that the number of invalids per 1,000 population rose steeply after the age of 60. More adequate treatment for their special needs; this required a different type of organization for their special needs; this had been referred to in the recently published Report of the British Medical Association on the care of the aged sick. This postulated the provision of geriatric departments in each district hospital of the Regional Hospital Boards. Pilot units in this country were working on these lines, and the results had been very gratifying. Patients could be transferred to appropriate long-stay annexes only when it was considered that maximum improvement had been attained. Thus there would be long-stay annexes for the sterile confining ambulant, for the permanently bed-fast, for the senile confining states, and for those patients whose needs were largely residential and nutritional. The most important specialists in a geriatric department were, first, a general physician experienced in the diagnosis and treatment of aged patients; secondly, a psychiatrist. It was unfortunate that the psychological difficulties of the aged were so little appreciated, because many of the senile confining states rapidly responded to treatment.

## Reviews

### MONGOL AND CRETIN

*Mongolism and Cretinism.* By Clemens E. Benda, M.D. (Pp. 310; 101 illustrations. 25s.) London: William Heinemann, Ltd. 1947.

Among the many problems associated with mental deficiency there are none so interesting as those which concern that type known as mongolism. The physical and psychological manifestations give a picture so uniform, and its prevalence irrespective of nationality is so evident, that it is no cause for surprise that various theories of its aetiology have been without being founded on fact—for example, racial regression, hereditary factors, syphilitic taint, and fertility exhaustion. Sporadic cretinism on the other hand, which is in some ways comparable, has a simpler aetiology, and its pathology is now well understood.

Dr. Clemens E. Benda, utilizing his unique opportunity as Director of the Wallace Research Laboratory at the great institution of Wrentham, Mass., has made a comparative study of these two forms of mental deficiency and has published his results in a book of the first importance. It has been estimated that mongol defectives form about 5% of the mentally deficient of all groups. Benda quotes Beidleman that mongolism occurred in 3.4 per 1,000 births at a large maternity hospital. Considering that to be an average sample of children born in the U.S.A. he calculates that between 6,000 and 9,000 mongols are born every year, and that, if their expectation of life is assumed to be ten years, at any given time there will be some 60,000 mongols in the population. The statistical surveys reveal other facts—notably the great rarity with which the condition occurs in more than one child in the family. Benda, who found two such cases in 400 families, quotes Orel as having collected 21 cases in the literature. Parents of a mongol are always fearful lest they may have a second, a point on which they can be reassured. The statement that mongolism occurs most frequently in a large family (when the mother is nearing the climacteric) is not altogether borne out by the figures. Thus both Benda and Beidleman found 42% of mothers to be under 35 years of age. In a series of 255 mongol births the former found 124 (48.6%) to be the first or second child, Brousseau (772 mongols) gives 45%, and in another smaller series the percentage was 46.6%.

Valuable as they are, these dry bones of statistical enumeration are but a scaffold round the main thesis—the pathological and histological investigations which form the chief part of the book. The author discusses each endocrine gland in turn and illustrates them by beautifully reproduced photomicrographs. He concludes that mongolism is a congenital hypopituitarism. The format and illustrations are remarkably good, and the book is likely to remain for a long time the standard work on mongolism.

G. A. AUDEN.

### NOTHING BY MOUTH

*Parenteral Alimentation in Surgery with Special Reference to Proteins and Amino Acids.* By Robert Elman, M.D. (Pp. 284; illustrated. 21s.) London: Hamish Hamilton Medical Books. 1947.

Until recently the results of progress made in the development of surgical procedures were impaired by the frequency of infection, collapse, or shock after operation, but advances in chemotherapy and transfusion techniques have now improved the situation. Blood transfusion is a form of parenteral alimentation as well as a means of rectifying the physiological imbalance due to oligæmia. Many types of fluid and food are used for parenteral alimentation. By this means, when the patient is unable to ingest, digest, or absorb sufficient food, it is possible to give essential nutrients—water, electrolytes, amino-acids, carbohydrates, and vitamins. Fat is not generally administered parenterally, since there is no stable emulsion that can be safely introduced into the circulation. In future intravenous fat will most probably become available as a means of giving much of the caloric requirements parenterally. It should be noted, how-

ever, that there has been a tendency to resort to parenteral alimentation in certain conditions which do not justify this procedure.

In this monograph, which was awarded the quinquennial Samuel D. Gross Prize of the Philadelphia Academy of Surgery for 1945, Elman gives a full account of the development and use of the various forms of parenteral alimentation. We welcome this account from the pen of one of the leading exponents of this method of feeding. As he points out, discussion of this mode of treatment is as appropriate to medical as to surgical patients. He pays special attention to protein and amino-acids, for he has had great experience of them.

In his introduction the author gives a most interesting history of the development of transfusion techniques. He credits Sir Christopher Wren with being the first person to introduce fluids intravenously. He then describes the general indications for and method of parenteral administration of fluids, with an adequate consideration of the factors leading to untoward reactions. There follow discussions on the requirements for water and electrolyte, energy-yielding nutrients, and vitamins. In the remaining two-thirds of the book he considers the protein needs of the body, protein deficiency, and the methods of parenteral protein administration, including the transfusion of plasma, amino-acids, and hydrolysed protein. In the penultimate chapter he sets out a practical programme for parenteral alimentation, and finally he reviews the clinical results. A historical appendix summarizes the salient data in the development of this mode of alimentation, and there is a useful author-subject index.

D. P. CUTHBERTSON.

### LEPROSY

*A Practical Textbook of Leprosy.* By R. G. Cochrane, M.D., Ch.B., F.R.C.P., D.T.M.&H. With foreword by George R. McRoberts, M.D., F.R.C.P., D.T.M.&H. Oxford Medical Publications. (Pp. 283; illustrated. 42s.) London: Geoffrey Cumberlege, Oxford University Press. 1947.

It has been calculated that there are about 1,200,000 people in India suffering from leprosy, and Dr. Cochrane says, "It is probably not an exaggeration to state that there may be as many as 300,000 cases of leprosy in the Madras Presidency alone." This statement itself is sufficient to justify the writing of a book discussing particularly leprosy as it is found in Madras. Dr. Cochrane writes from long experience, and the 22 chapters of his book are a rich mine of information on every aspect of the subject, though some of the seams may be rather hard to excavate. The 174 illustrations are excellent—photographs of lesions, photomicrographs of sections, pictures of buildings and rural scenes, and two coloured representations of *Mycobacterium leprae* in the tissues. These, even apart from the text, form an atlas of leprosy sufficient to make the book well worth studying.

The author deals with every feature of leprosy and gives a wealth of practical detail—perhaps most fully in the epidemiological and preventive aspects, and all who survey the problem or combat the disease should study these sections carefully. He fully discusses treatment with hydnocarpus oil, as well as the treatment of lepra reaction, neuritis, and other complications, but refers to the more recent sulphone therapy only in a few sentences. He adds a paragraph on the requirements for testing new remedies, which include facilities for histological work and a person capable of interpreting the sections. "If everyone would avoid publishing the results of treatment for two years much disappointment would be avoided."

The book unfortunately has some textual mistakes, and there are a few statements which have to be interpreted not as they read but in the light of the context. These defects are doubtless due to the author's absence in India making it difficult sufficiently to correct the proofs.

E. MUIR.

### BONE-MARROW CULTURE

*La Cultura in Vitro del Midollo Osseo.* By Aminta Fieschi and Giovanni Astaldi. (Pp. 309; illustrated. 1,000 lire.) Pavia: Tipografia del Libro. 1946.

In nine years of research into the application of tissue-culture methods to the problems of haematology Fieschi and Astaldi have accumulated much useful information, which they have summarized and reviewed in this book on bone-marrow culture.

They are not concerned with studies of cell metabolism, and for morphological studies they use a relatively simple technique. Bone marrow obtained by sternal puncture is transferred to a 4:1 mixture of plasma and chick-embryo extract. After this has coagulated, the culture is covered by a similar fluid medium prepared from serum, which has to be renewed every one or two days. For direct observation and for the preparation of smears the solid part of the culture may be made on cover-slips. The authors find the principal evidence for most of their interpretations in stained smears, and their successful results, illustrated in good photomicrographs and coloured plates, will make many wish to try their methods. They briefly consider other work on the subject and their own results with normal marrow in terms of Ferrata's theories of haemopoiesis, and then discuss in full their findings in pernicious anaemia, the leukaemias, and erythroblastic anaemia.

The book is interesting in spite of many repetitions and lengthy discussions, and some of the conclusions are remarkable. The marrow cells in cases of relapsed pernicious anaemia tend to mature normally in culture. In marrow taken immediately after beginning liver therapy basophil megakaryoblasts undergo early normoblastic maturation. Cells in cultures from cases of chronic leukaemia survive only as long as their normal counterparts, while those from cases of acute leukaemia can survive to a time when normally the parenchymatous tissue has been replaced by fibroblasts and macrophages—a difference connected with the relation of the leukaemias to malignant growths. The authors promise further investigation into this and other problems. Meanwhile they have produced a stimulating and well-documented work which many haematologists will wish to have in their library.

L. P. R. FOURMAN.

### SKIN DISEASES

*The 1946 Year Book of Dermatology and Syphilology.* Edited by Marion B. Sultzberger, M.D.; Assistant Editor, Rudolf L. Baer, M.D. (Pp. 638; illustrated. \$3.75 or 21s.) Chicago: The Year Book Publishers. London, H. K. Lewis and Co. 1947.

The indefatigable editors of this series have produced another very useful summary of a year's dermatological progress. As usual, they begin their volume with an article of some length on a topic of interest to both dermatologists and general physicians; and this year they discuss advances in management, drawing attention to several new remedies of great interest. Within the last few years a number of promising new drugs have been discovered, such as the sulphonamides, penicillin, tyrothricin, streptomycin, and the quinolines, and the editors carefully consider their advantages and disadvantages, their indications and contraindications. They also discuss the recent antihistamine drugs and—perhaps the most striking recent advance in skin therapy—the treatment of lupus by large doses of calciferol. It is impossible to summarize their remarks on all these matters here, but their attitude throughout is well balanced. After a formidable table of the dermatological dangers of penicillin they conclude that, "although valuable in exceptional cases, penicillin is *not* particularly valuable as a topical medicament for general use against bacterial infections of the skin." Medical men in Britain might bear this admonition in mind, for some now treat almost every skin case with penicillin cream as a routine, sometimes with deplorable results.

In addition to the introductory essay the *Year Book* presents most of its familiar features, including good abstracts of the dermatological literature of the year. Probably every important paper is mentioned, and the illustrations are well chosen and well reproduced. The "Quiz" on the jacket will reveal to many readers how numerous are the questions on recent dermatological work that they cannot answer, and, it is to be hoped, will prompt them to fill the gaps in their knowledge. We again recommend this book.

H. HALDIN-DAVIS.

*Transactions of the American Therapeutic Society*, Volume XLIII, 1943, edited by Francis M. Pottenger, jun., and published by the Society, contains the papers given at the Society's 44th and 45th annual meetings. Of most of them it can be said, in the words of one of the authors, "These observations are not original, but they are personal." They will therefore be of more interest to those who attended the meetings, and may wish to have some permanent reminder of what was said, than to the general medical public.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Kingdom of the Lost.* By J. A. Howard Ogdon. (Pp. 256. 10s. 6d.) London: The Bodley Head. 1947.

The author describes his recovery from schizophrenia with the aid of yoga.

*Recent Advances in Sex and Reproductive Physiology.* By J. M. Robson, M.D., D.Sc., F.R.S.Ed. 3rd ed. (Pp. 336. 21s.) London: J. and A. Churchill. 1947.

A summarized account of recently acquired knowledge of the reproductive system.

*A Short Textbook of Surgery.* By C. F. W. Illingworth, C.B.E., M.D., Ch.M., F.R.C.S.Ed. 4th ed. (Pp. 680. 30s.) London: J. and A. Churchill. 1947.

Includes new material on anticoagulants, thiouracil, protein hydrolysates, arterial injuries, and nerve injuries.

*The Occasion Fleeting.* By Hugh Barber, F.R.C.P. (Pp. 199. 15s.) London: H. K. Lewis. 1947.

Essays on the art of medicine.

*The Parathyroid Glands and Skeleton in Renal Disease.* By J. R. Gilmour, M.R.C.P. (Pp. 157. 18s.) London: Oxford University Press. Geoffrey Cumberlege. 1947.

An account of the parathyroid gland in 90 cases of renal disease.

*The Treatment of Rheumatism in General Practice.* By W. S. C. Copeman, O.B.E., M.A., M.D., F.R.C.P. 4th ed. (Pp. 258. 12s. 6d.) London: Edward Arnold and Co. 1946.

An account of acute and chronic rheumatic disorders and their treatment; for the general practitioner.

*Clinical Studies in Psychopathology.* By H. V. Dicks, M.A., M.D., M.R.C.P. 2nd ed. (Pp. 238. 15s.) London: Edward Arnold and Co. 1947.

Indented for the practitioner with clinical experience of the psychoneuroses.

*The Child's Lung.* By Stefan Engel, M.D. (Pp. 332. 40s.) London: Edward Arnold and Co. 1947.

An account of the structure, function, and diseases of the lung in children.

*An Atlas of Dental Histology.* By E. B. Manley, M.Sc., D.C.S. B.D.S., and E. B. Brain, F.I.B.P., F.R.P.S. (Pp. 49. 12s. 6d.) Oxford: Blackwell Scientific Publications. 1947.

Presents photomicrographs of dental tissues, and includes a section on histological technique.

*The Shakespeare Circle.* By C. Martin Mitchell. (Pp. 116. 12s. 6d.) Birmingham: Cornish Brothers, Limited. 1947.

A biography of Dr. John Hall, Shakespeare's son-in-law.

*National Insurance.* By John Gazdar, LL.B. (Pp. 74. 3s.) London: Stevens and Sons, Ltd. 1947.

A simply written account of the effects of the National Insurance Act, 1946.

*Die Klinik der energetisch-dynamischen Herzinsuffizienz.* By Robert Hegglin. (Pp. 120. 19 Swiss francs.) Basle and New York: S. Karger. 1947.

A monograph on cardiac insufficiency in metabolic disorders.

*The Epidemiological Significance of Grouping and Typing the Haemolytic Streptococci.* By Jörgen Ernst. (Pp. 379. 25 Danish crowns.) Copenhagen: Ejnar Munksgaard. London: Humphrey Milford, Oxford University Press. 1942.

The author discusses particularly scarlet-fever epidemics and endemics.

*Introduzione allo Studio dei Protozoi Parassiti dell' Uomo.* By Augusto Corradetti. (Pp. 100. No price.) Rome: Istituto Superiore di Sanità. 1947.

Includes the study of entamoebae, trichomonads, trypanosomes, and plasmodia.

*La Science de L'Hypnotisme.* By E. Bérillon. (Pp. 373. 14 francs.) Paris: Librairie Jouve et Cie. 1946.

The use of hypnotism in psychotherapy.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 29 1947

## FOR AND AGAINST B.C.G.

We have referred editorially on several occasions during the past few years to the possibility of using B.C.G. vaccine in this country. It is now twenty-five years since it was first used in France: in other countries, notably Denmark, Norway, and Sweden, the method of employing it has been improved, and careful studies have been made which appear to afford sound evidence of its value. A considerable body of opinion among those interested in the treatment of tuberculosis in this country is in favour of the method, and recently an influential deputation requested the Minister of Health to sanction the use of the vaccine and to make it available. It is understood that the possibility of acceding to this request is being explored. Presumably the vaccine could be obtained from abroad until arrangements can be made for its manufacture here.

In a paper read to the International Congress of Physicians in London on Sept. 12, which we publish on page 855, Prof. G. S. Wilson takes, as he describes it, the part of devil's advocate, and marshals the arguments against the use of B.C.G., in order at least that we may be quite clear about what we are doing if it is to be introduced. He first criticizes the statistical evidence of its efficacy. It is generally admitted that the original observations in France mean very little; they were also based largely on oral administration, which has now been abandoned in favour of some form of injection. Among studies employing present-day methods that of Wallgren is vitiated by the absence of controls and that of Levine and Sackett in New York by a faulty method of selecting controls, while that of Rosenthal and his colleagues in Chicago affords incomplete information in several particulars. All these workers used the vaccine in infants. Among those who have given it to nurses Ferguson had no controls, and Heimbeck, whose work in Norway is generally considered to provide the surest backing for B.C.G. as a prophylactic, employs a method of presenting his results which involves a fallacy. Finally, although Aronson and Palmer's results among North American Indians are acknowledged to be very suggestive, it is pointed out that effects observed in so highly susceptible a race will not necessarily be duplicated in white peoples possessing a higher degree of basic immunity. Lest these well-founded criticisms should have an unduly deterrent effect, it is perhaps as well to remember that Wilson is deliberately arguing from the negative standpoint, and that a more difficult subject on which to produce statistically unassailable evidence is scarcely conceivable. The disease being one of low incidence and extreme chronicity, large numbers of persons must be observed for a period of years. We should also not forget that in the more manageable experimental field the immunizing power of B.C.G. has been well demonstrated; moreover, in the

human subject present-day methods of using it induce tuberculin-sensitiveness regularly. It may not be justifiable to transfer without qualification to ourselves conclusions based on effects in guinea-pigs, calves, or even American Indians, but at least the theory is sound and there is some expectation of the desired effect.

Everyone will agree with Wilson that if we are to use B.C.G. its first use should take the form of a properly controlled further investigation rather than the liberation of the vaccine for anyone to do what he likes with it. It is an important point that untoward effects from the vaccine in infants might easily prejudice subsequent immunization against diphtheria. Whatever method is employed, the effects of a living vaccine are always liable to take a form which will excite public animosity. B.C.G. injected subcutaneously gives rise to an abscess in a small proportion of cases; intracutaneous injection may result in an ulcer; and the multiple-puncture method, though rarely causing a destructive lesion, produces up to forty rather angry-looking red papules which persist for weeks. Care in the maintenance of the culture will ensure that untoward effects are rare, but they cannot entirely be eliminated. In the preparation of the vaccine a nice balance has to be struck between a degree of avirulence which renders it ineffective and an approach towards virulence which leads to the production of local lesions. An interesting account is given by K. A. Jensen<sup>1</sup> of the behaviour of B.C.G. at the State Serum Institute, Copenhagen, where he was responsible for preparing the vaccine for use in Denmark between 1927 and 1941. Two strains were used during that time, of which one was not sufficiently avirulent and had to be abandoned. The condition of the other could be kept fairly constant by interposing a few transfers on bile-potato medium after a series of generations on the Sauton medium employed for making the vaccine. Jensen has also devised an accurate method of assessing virulence, which consists in injecting four different doses intradermally into guinea-pigs and observing the exact duration of each nodule produced. One can well understand his reluctance, expressed at the International Congress for Microbiology last summer, to embark on the use of an alternative vaccine made from Wells's vole bacillus. His attitude was that, having spent twenty years in learning how to manage B.C.G., he had no wish to start again from the beginning. It should perhaps be added that the vole bacillus might well prove not to need so much managing.

That B.C.G. vaccination has disadvantages there is no denying, and everyone will demand with Wilson that the gains from it shall be commensurate. Where everyone will not follow him is when he seems to suggest that the need for a method of immunization against tuberculosis has been exaggerated. He mentions the fact that during the whole of the Prophit survey only two nurses under observation died of tuberculosis, "giving an annual mortality rate one-third of that for the female population of corresponding age in England and Wales." This isolated fact is misleading. It is generally conceded that nurses more often develop tuberculosis than comparable women in other occupations, and if our information refers only to morbidity and not to mortality it is because a follow-up

<sup>1</sup> *Acta tuberc. scand.*, 1946, 20, 1.

which will yield information on the latter has yet to be made. Authors adducing evidence of a high incidence of tuberculosis among nurses are Heimbeck<sup>2</sup> himself, E. L. Ross,<sup>3</sup> H. L. Israel *et al.*,<sup>4</sup> and D. W. Carmalt-Jones<sup>5</sup>: the last-named includes a comparison with female students of other subjects at the same age. The findings in the Prophit survey<sup>6</sup> deserve to be given more fully. The number of nurses on which conclusions are based was 2,572, and they were under observation for an average period of 2.8 years. They presumably included some who were first examined when the survey began in 1934, and had thus been observed for 8 years up to 1942, at which point for this purpose the survey terminated. They must also have included many observed for much shorter periods, and, too, some who were untraced and whose fate, if known, might have added to the number of those with tuberculosis. The number initially Mantoux-negative was 452, and of these no fewer than 33 (7%) developed clinical tuberculosis. It is true that only 2 of these nurses had died when the report was written, but 2 had spinal caries, 1 advanced tuberculous laryngitis, and 4 others active pulmonary disease; in the remainder the lesion was stated to be "arrested," "quiescent," "healed," or "recovered," but any such description can be only provisional in this disease. Of the originally Mantoux-positive 2,120 nurses only 43—a much lower proportion—had developed tuberculosis; the disease was still active in 14 and "quiescent" in 19. If the number of deaths in this series could be stated ten or even twenty years hence the picture would be very different: tuberculosis is a disease which takes a long time to kill. For the same reason the fact that only 1 child in 1,740 dies of tuberculosis in the first year of life does not present a true picture of the mortality from infection acquired at this time.

We would therefore question the conclusion that there is not enough to be gained by the use of B.C.G. even if its efficacy is proven. Any feasible method that will demonstrably increase resistance to tuberculosis in certain classes of person is surely well worth while. These classes certainly include tuberculin-negative nurses, and infants in infected households. It is possible, as Wilson suggests, that to aim at protection from undue exposure to infection would be a better policy, but this is even more difficult than it sounds: one of the chief dangers to nurses is the undiagnosed case, sometimes in a surgical ward. There is a field of usefulness for B.C.G. if the claims made for it are accepted. It seems a reasonable view that some contribution from this country to the study of this subject is overdue.

### THE WANING POWER OF PENICILLIN

It has been a general experience for some time past that penicillin-resistant staphylococci are encountered with increasing frequency. Almost unheard-of in the early days of penicillin treatment, they now form a substantial proportion of strains from patients for whom such treatment is contemplated, and usually cause it to fail. The magnitude

of this unwelcome change will be appreciated from the careful observations of Dr. Mary Barber, published in this issue of the *Journal* (p. 863). Of two hundred strains cultivated from patients at the Hammersmith Hospital during 1947, 12.5% were penicillin-resistant, or 14.1% if only those are considered which were derived from actual lesions. During the first half of 1947, only strains from actual lesions were tested, and in one hundred such the number found to be resistant was no less than thirty-eight. The main interest of these observations is their bearing on the future efficacy of penicillin treatment, but they involve two other matters with which this paper chiefly deals. One is the method used for testing sensitivity, and in this connexion it is perhaps not generally understood that when an organism forms penicillinase quite misleading results may be obtained by certain conventional methods if the size of the inoculum is not controlled. Fortunately a very fair picture of the true state of affairs can be obtained by applying the diffusion principle in primary culture, whether by the "ditch" method, as illustrated here, or by the use of "cups" in which solutions of different strengths are placed.

The second and more fundamental aspect of the subject with which Dr. Barber's paper deals is the origin of resistant strains. There is now a considerable literature dealing with the question whether the acquisition of penicillin-resistance in bacteria generally is the result of selection or of mutation. As it concerns staphylococci any answer to this question must take account of the fact that there are two quite distinct types of resistance. This was first pointed out by W. W. Spink and Viola Ferris,<sup>1</sup> who observed that whereas staphylococci artificially habituated to penicillin *in vitro* rapidly lost this property on transfer to normal media, and did not owe it to forming any inactivating substance, naturally resistant strains or those apparently acquiring resistance *in vivo* were permanently resistant, and contained a substance which was a potent inactivator of penicillin. That this substance is in fact penicillinase was shown by A. Bondi and Catherine C. Dietz.<sup>2</sup> Others who were early in recognizing this important distinction were J. E. Blair *et al.*,<sup>3</sup> and E. A. North and R. Christie,<sup>4</sup> who also demonstrated that naturally acquired resistance is accompanied by no loss of pathogenicity, whereas organisms artificially rendered resistant lose this property. These authors also claim to have shown in one patient that a highly resistant staphylococcus recovered after penicillin treatment was identical serologically and in every other property with the more sensitive strain isolated a fortnight earlier. This observation favours the mutation hypothesis, and is in conflict with the interesting finding reported in the present paper that sensitive and resistant organisms derived from the same patient, the former predominating before treatment and the latter entirely replacing them after it, were distinct both serologically and by phage typing. It is evidently desirable that further observations on these lines should be made, but common sense appears to favour the view held by Dr. Barber. There is no reason why two quite distinct types of resistance should result from habituation to penicillin, one in a test-tube and the other in the body, nor is the capacity

<sup>2</sup> *Arch. Intern. Med.*, 1928, 41, 336; 1931, 47, 901.

<sup>3</sup> *J. Immunol.*, 1946, 62, 281.

<sup>4</sup> *Med. J. Austral.*, 1946, Feb. 9, 176.

to form penicillinase a property likely to be acquired in such a way. The best explanation of the facts is that penicillinase-producers are naturally resistant, and from very small beginnings are rapidly coming to occupy the places left vacant by their more vulnerable cousins.

The meaning of this for the future of penicillin treatment needs little emphasis. It is a problem not peculiar to staphylococcal infection, although more serious in relation to this than to any other. The capacity of staphylococci to acquire resistance, at least artificially *in vitro*, is very great; whether naturally resistant strains reach the same levels, or can increase their form of resistance in response to the same stimulus, is not clear. But in so far as *in vitro* behaviour is any guide, the findings of E. W. Todd and his colleagues<sup>5</sup> are of interest: whereas the resistance of *Staph. aureus* could be raised 3,000-fold (and others have since exceeded this figure) that of a pneumococcus could be raised only 27-fold and of *Strep. pyogenes* 5-fold. Thus we have less to fear from the latter at all events, but in view of its much greater sulphonamide sensitivity we may well wish that the two could change places in the matter of their long-term reaction to penicillin. It is for its power over grave staphylococcal infections that we have always had most reason to be grateful for the discovery of penicillin, and that power is already well on the wane. We must indeed look to a future in which the problem of treating these infections has almost to be faced afresh. Streptomycin is unlikely to do more than help to bridge a short gap between penicillin and some new form of chemotherapy: there are already abundant records to show that staphylococci, like other species, may acquire immense resistance to this antibiotic within a very short time. There is little that can be done to delay the time when a majority of staphylococcal infections will be resistant, at least to a dangerous degree, to treatment with penicillin. The correct policy is to test the sensitivity of the organism in each case, and to give from the first a dose which should be adequate to control it. This is not universally feasible, but another useful measure within the capacity of every practitioner is to restrict the use of penicillin to cases in which there are clear indications for it. The present enormous consumption of the drug can be accounted for only by a good deal of indiscriminate use, and it is generally considered that widespread use, particularly of inadequate doses, is a potent factor in breeding resistant strains of bacteria.

### RELIEF OF PAIN IN PELVIC CANCER

Incurable cancer of the pelvic organs, both male and female, is seen so frequently that it is surprising that more attention has not been paid to measures for relieving the distressing pain which usually marks its terminal stages. Greenhill and Meave Kenny, in articles elsewhere in this issue of the *Journal*, both point out that the usual treatment with ever-increasing doses of opiates has serious disadvantages in that it causes mental as well as physical deterioration and makes the patients' last days a trial both to themselves and to their attendants. The problem as it applies particularly to carcinoma of the cervix was fully discussed in 1937 in an important article by T. F. Todd,<sup>6</sup> who described

in detail the technique, indications, and limitations of pre-sacral neurectomy and intrathecal injection of alcohol—procedures which had been introduced several years earlier. However, it is probably true that they have not been used as often as they should, and Greenhill's reminder of their value is timely.

Todd emphasized that if renal pain is excluded pelvic cancer brings on two types of pain which must be differentiated if they are to be treated effectively. The pain caused by a lesion limited to the viscera is diffuse, bursting, or spasmodic in character, and can be relieved by resection of the pre-sacral nerve if not by a more direct surgical approach such as hysterectomy for pyometra following radiotherapy. The other type of pain is one which follows the distribution of one or more of the lumbo-sacral nerve roots into the lower limbs, and it is usually assumed that it is the result of the sacral plexus becoming involved in the neoplastic or inflammatory process. Todd points out, however, that there is rarely any evidence of this and the pathogenesis of root pains is obscure. When they occur it becomes necessary to block all the impulses travelling via the somatic nerves and spinal cord if relief is to be obtained. This has been done by chordotomy, but most would regard this as a formidable operation which is hardly justifiable in the circumstances. The injection of alcohol around the spinal cord in the lumbar region is preferable in that it is not only reasonably effective but is simple and free from serious risk. It is not devoid of all risk, however, for in addition to the usual hazards of spinal puncture it is sometimes followed by temporary loss of control of the sphincters and other sequelae implying damage to the spinal cord. Although these possibilities are not so serious as to outweigh the potential benefits to a patient whose outlook is hopeless, they make it necessary to emphasize that nearly all writers are agreed that intrathecal alcohol should be used only in cases of incurable malignant disease. It is therefore particularly important, though it may be difficult, to distinguish between a recurrence of growth and late tissue reactions to radiotherapy. Such reactions, sometimes resulting in fistula formation, are not infrequently seen in cases of carcinoma of the cervix and are thought to be the result of ischaemia. For these Todd advocates pre-sacral neurectomy, arguing that it not only relieves the intense pain which they cause, but that it may assist the healing process by producing vasodilatation.

The operation of pre-sacral neurectomy has no significant ill effects and can be used in the treatment of chronic pelvic pain caused by innocent as well as by malignant lesions. It is perhaps not quite so easy to perform as is implied by Greenhill, for the nerve fibres are usually widely dispersed and division of them all, which is essential for a good result, necessitates a fairly wide dissection of the area as far out as the ureters on each side. These, as well as the left common iliac vein and middle sacral vessels, are therefore exposed to risk. Moreover, it is not an uncommon experience to find visceral pain persisting after pre-sacral neurectomy, and it may be that in some cases more relief would be obtained if the autonomic nerves accompanying the ovarian vessels were also resected, as described by O'Donel Browne<sup>7</sup> for the treatment of ovarian dysmenorrhoea. Also it is possible, if not probable, that some sensory impulses are carried via the inferior hypogastric plexus and the visceral branches of the second, third, and fourth sacral nerves.

Epidural injections for the relief of pain in the pelvis and referred pain in the legs is also a comparatively old procedure, procaine (novocain) and saline having been used in the treatment of some forms of sciatica as well as pelvic

<sup>5</sup> *British Med. Journal*, 1945, 2, 603.

<sup>6</sup> *Lancet*, 1937, 2, 555.

<sup>7</sup> *J. Obstet. Gynaec. Brit. Emp.*, 1939, 45, 982.

carcinoma. By such means Todd was able to give patients suffering from carcinoma of the cervix relief for as long as six to eight weeks. Meave Kenny now describes a modification in which 40-60 ml. of "proctocaine" are used, and claims that this agent relieves the pain for one to four months, at the end of which time the injection can be repeated. She considers that the method is so simple and free from risk that it can be carried out in the patient's home. Injections into the sacral canal, however, demand some detailed knowledge of the anatomy of the area, and are not always so easy to place as might be imagined, even for those well versed in the technique; various accidents due to the injection of analgesic solutions behind, or in front of, the sacrum or into a low-lying subarachnoid space have been described. Some medical men may therefore hesitate to tackle this procedure in domiciliary practice and may find it easier to carry out the ordinary spinal puncture which is all that is necessary for injections of alcohol. This, however, should not be allowed to interfere with further trials of extradural injections of proctocaine, for they may well prove to have special advantages.

Valuable as they are, none of these methods can be relied on to relieve pain in all cases, and the duration of relief, when obtained, is variable. Some patients experience both visceral and somatic pain and require two types of treatment. If blocking of the spinal roots or pathways is to be successful the agent must be applied at or above the level of the roots carrying the sensations from the affected part. So far as resection of autonomic nerves is concerned, further progress is to some extent hindered by the incompleteness of our knowledge of the sensory pathways from the various pelvic viscera.

### PREGNANCY AFTER LUMBO-DORSAL SYMPATHECTOMY

Diseases such as phthisis and valvular disease of the heart in young women often become complicated by pregnancy and may then present difficult clinical problems. Another example is chronic hypertension, which was discussed by Browne<sup>1</sup> recently. In a leading article<sup>2</sup> commenting on his work reference was made to Adson and Allen's<sup>3</sup> report of a case of chronic hypertension treated by lower thoracic sympathectomy with good effect. A subsequent pregnancy, however, resulted in a rise in the blood pressure, which returned to normal only when abortion was induced. M. M. Peet<sup>4</sup> had a similar experience with a woman who suffered from malignant hypertension. That pregnancy does not always have such an adverse effect in this type of case is shown by J. L. Newell and R. H. Smithwick,<sup>5</sup> who gave an account of 14 patients successfully treated by lumbo-dorsal splanchnicectomy for benign or malignant hypertension. All these women conceived afterwards except one who was pregnant at the time of the operation. In 9 cases the blood pressure during pregnancy remained within normal limits; in the other 5 there was a significant rise during the last three months. One patient developed heavy albuminuria necessitating caesarean section at the thirty-fourth week. Only one baby was lost, but its mother had a living child the following year. All the women survived the pregnancy and were as well afterwards as before, so Newell and Smithwick conclude that given careful supervision it is permissible and safe for certain women to undertake child-

bearing after they have been successfully treated for hypertension. They note that women in the younger age groups tolerate pregnancy best. Study of the reports of published cases suggests that hypertensive subjects previously treated by sympathectomy react to pregnancy in a similar way to that of the untreated. None suffer permanent deterioration in their condition. Some go through pregnancy without any further rise in blood pressure, whereas others sustain sooner or later an increase in blood pressure and sometimes albuminuria as well. Also, in the description of one case there is a suggestion that there was a fall in blood pressure during the middle third of pregnancy.

One aspect of these cases of interest to the obstetrician and to the physiologist is the effect of such an extensive sympathectomy on uterine action. Unfortunately Newell and Smithwick make only brief mention of this. Caesarean section was carried out in three cases but in the remainder the comments suggest that pregnancy ended in normal delivery. One patient, however, is noted as having had a short and painless labour, and a second had no pain until the foetal head distended the perineum.

### INFANT MORTALITY AND SOCIAL CONDITIONS

The association of infant mortality with environmental and economic conditions is so well established that the former is generally accepted as an approximate index of the latter. Woolf<sup>1</sup> in a study of the infant mortality in the county boroughs during 1928-38 has used seven indices of social conditions: (1) percentage of families with more than one person per room; (2) average monthly percentage unemployment among insured adult males; (3) percentage of occupied males in Social Classes IV and V; (4) percentage of females aged 14 and over employed in manufacture; (5) degrees of latitude north of 50°30'; (6) gross reproduction rate; (7) weighted index of persons per acre. He examined the problem in great detail by means of multiple regression equations, obtaining equations in terms of the seven social indices for total infant mortality, age at death, stillbirths, and causes of death. An attempt was made to allot to each of the social indices the proportion of the infant mortality for which it was responsible. By inserting in the equation a zero value for the first four indices, putting the value of latitude at 50°30' (the extreme south of England), the gross reproduction rate at 0.6, and by using a weighted index of overcrowding at 2.6 persons per acre, the author obtained a minimum mortality which he termed the rate among the "better-off" population. By putting the overcrowding index at 100% and the percentage of persons in Social Classes IV and V at 100, the gross reproduction rate at 1.6, density at 80, and taking the mean latitude, a value was found for the "crowded poor"; and by putting the unemployed at 100% in this equation a value for the "unemployed crowded poor" was obtained.

The scope and limitations of the regression equation are very briefly indicated, but, since there is a tendency to-day in many inquiries to follow a set statistical procedure without consideration of the practical applications of the results, it would have been better if the author had emphasized the limitations of the method he employed. This aspect is important, especially in a scientific inquiry of socio-medical problems, for they have an emotional appeal and the general reader may draw unwarranted conclusions. Given a set of social indices of a county borough the expected infant mortality can be determined from the regression equation, and the agreement between the

<sup>1</sup> *British Medical Journal*, 1947, 2, 283.

<sup>2</sup> *Ibid.*, 1947, 2, 301.

<sup>3</sup> *Ann. Intern. Med.*, 1938, 11, 2151.

<sup>4</sup> *J. Int. Chir.*, 1940, 5, 1.

<sup>5</sup> *New Engl. J. Med.*, 1947, 236, 851.

<sup>1</sup> *Brit. J. Soc. Med.*, 1947, 1, 73.

"observed" and "calculated" values may be quite good, although even with seven indices the prediction is far from perfect. Extrapolation is not permissible, nor can it be argued that a reduction in the size of the indices in any town would lower the infant mortality, since correlation is not necessarily causation. If therefore we were given the values of the indices of some urban area of the same general socio-economic type as those used to calculate the constants of the equation and, even more important, if the values of the indices were within the range of values used to obtain the constants, it is likely that we should predict the infant mortality quite well; but if the values were outside the range the prediction might be wildly inaccurate. To assign shares on the basis of an equation such as this to the different indices in a material sense may be quite wrong. The indices, purposely chosen because they correlate with infant mortality, may be only indirect measures of the true cause, which is probably much more complex than a simple equation suggests. There is, for instance, no evidence that latitude itself has any direct bearing on infant mortality; the rate for Sweden and Norway was considerably below that for England and Wales in the pre-war period. In England, for various reasons, industrialization and its attendant evils started in the North, with the result that there is a geographical distribution of highly industrialized towns. Latitude, therefore, may be regarded as an indirect index of social conditions and not as an independent cause affecting infant mortality. The ideal population postulated by Woolf obviously can never exist. The concentration of the county boroughs into the South of England is incompatible with a density of 20 persons per acre; neither is it practicable that women should be excluded from industry. The present tendency is possibly towards employing larger numbers of women than in the pre-war years. With a gross reproduction rate of 0.6 the great problem would be that of increasing the birth rate and not of decreasing the infant mortality.

Nobody doubts that economic factors influence the level of the infant mortality; it would, however, be going much too far to infer from analyses such as this that economic factors are of supreme importance. The elimination of adverse environmental conditions would decrease the mortality, but by what extent is merely a matter of conjecture. A variety of factors, not all economic, contribute to infant mortality, but it is of course possible from published data to inquire only into the broad aspects of the problem, and a field inquiry would be necessary to obtain more details. These factors and their possible influence on infant mortality must be considered to appreciate the complexity and extent of the problem. Hereditary factors must play some part, but they can be ignored when considering how infant mortality can be reduced, since it is hardly likely that unsuitable stock will ever be prevented from breeding. The care and nurture of babies is of primary importance, but only a very small proportion of indifferent parents in the population is needed to make a large difference to the infant mortality rate. Thus a waste of 2% of the births by criminal negligence, stupidity, or bad traditions in hygiene or feeding would increase the infant mortality by 20 per 1,000. Education has played an important part in reducing the wastage of infant life. The most obvious example of this is the reduction in the mortality from over-laying, which has fallen considerably during the past forty years. Some of the old notions of child management were also inimical to health—for example, the administration of a soothing mixture with a high laudanum content, which proved, on occasions, to be a too effective quietener. The importance of reasonable living conditions cannot be exaggerated, but the improvement of such conditions is a long-

term policy, since it will take some years to solve the housing problem. The immediate hope of still further reducing infant mortality appears to lie in the greater diffusion of knowledge about the welfare and nutrition of babies. Many children are still unnecessarily exposed to risks of infection because of the parents' fatalistic views on the common infectious diseases of childhood.

### A COMMITTEE ON CERTIFICATES

The Minister of Health and the Secretary of State for Scotland have appointed a committee of five to recommend "how far it would be practicable to reduce the number of certificates to be signed by medical practitioners." The full terms of reference are: "To consider the medical certificates required under present enactments or regulations, or for other administrative purposes, and to advise, without excluding the possibility of amending legislation, how far it would be practicable to reduce the number of certificates to be signed by medical practitioners and to improve and simplify the forms of certificate and the rules governing their issue." The committee members are as follows: Mr. Archibald Safford (chairman), Dr. J. Clifford Arthur, Miss Florence Hancock, Dr. Walter Jope, Mr. A. W. Neville, Mr. R. L. Briggs (Ministry of Health, Secretary). Mr. Archibald Safford is the Recorder of Faversham; Drs. Arthur and Jope, both general practitioners, are members of Council of the British Medical Association; Miss Florence Hancock is Chairman of the General Council of the Trades Union Congress and joint author of the Report on Post-war Organization of Private Domestic Employment, 1945; and Mr. A. W. Neville was formerly Principal Assistant Secretary in the Ministry of Health.

### LASKER AWARD TO GREAT BRITAIN

The American Public Health Association at its meeting in October presented to Sir Wilson Jameson one of the Lasker Awards for 1947 "for food control in Great Britain and its effect on the health of the people." This came under the designation of "Group Awards," and took the form of a silver statuette. The award was made to the "British Ministries of Food and Health and to the four great leaders in the historic enterprise—Lord Woolton, Sir Jack Drummond, Sir Wilson Jameson, and Sir John Boyd Orr." The citation refers to the setting up in 1937 of an Advisory Committee on Nutrition by the Ministry of Health, and the subsequent establishment of the Ministry of Food. It records the fall during the war of the rates of infantile, neonatal, and maternal mortality, and states that, "although almost all other environmental factors that might influence the public health deteriorated under the stress of war, the public health of Great Britain was maintained and in many respects improved." The Lasker Awards Committee considers that the combined effort of the Ministry of Food and the Ministry of Health during the recent war "has been one of the greatest demonstrations of public health administration that the world has ever seen."

We believe this is the first time that the American Public Health Association has made a Lasker Award to a Government Department of another country, and no better choice could have been made. The burden falling on the chief medical officer of the Ministry of Health during those years of unprecedented stress was great, and the group to whom the Award was made could have had no more fitting recipient of it than Sir Wilson Jameson. (See also p. 881.)

## THE NEWCASTLE-UPON-TYNE OBSTETRIC EMERGENCY SERVICE\*

BY

FRANK STABLER, M.D., F.R.C.S., F.R.C.O.G.

*Assistant to the Gynaecological Department, Royal Victoria Infirmary; Honorary Obstetrician, Princess Mary Maternity Hospital, Newcastle-upon-Tyne*

The Newcastle-upon-Tyne Obstetric Emergency Service has flourished since early in 1935, when it was founded by Prof. E. Farquhar Murray, and it is entirely due to his organization and enthusiasm that it has grown to its present strength. From that time until the end of 1946, 353 calls had been made, 8,356 miles travelled, 30 gallons of intravenous infusion given, and 37 women had died. It is felt that an assessment of its work would be timely.

This centre is probably unique in England for the reason that there is not another university centre within 120 miles to the northward and 90 miles to the southward. The furthest distances travelled have been: to the north, Berwick (64 miles); to the south, Barnard Castle (41 miles); and to the west, Haltwhistle (37 miles). The population in this area is about 2½ millions, though three towns—Sunderland, Stockton, and Darlington—have not made use of the facilities. With these exceptions arrangements for fees have been made with the local authorities. In 1935 only one call was made, but the next year there were 11, and by 1939 the number had risen to 47. The numbers fell during the war years, but rose in 1946 to a record of 56.

From time to time suggestions have been made that subsidiary centres should be established, and it is probably true that beyond thirty miles much of the value of the service is lost. There are, however, two necessities without which the service would be valueless. The first is frequent use: unless there is frequent need to resterilize the apparatus, and a quick turnover of blood and plasma, the use of these becomes dangerous. The second is that there should be available a person who is familiar with the urgent conditions met with, skilful, quick to handle infusion apparatus, and ready for any obstetric operation. While speed is desirable it is not nearly so important as these two factors, and it is unfortunate that the nickname "Flying Squad" has been applied to the service. The apparatus alone has always been available for use by any practitioner who wished; in actual fact, it has never once been called for without a request for the attendance of a consultant. In the early days of the service the aim was largely to render a woman temporarily fit to stand the ambulance journey to hospital. Intravenous saline was the most frequently used infusion, and it was not for some years that stored blood was available. Twenty-seven women who had suffered from loss of blood or shock were brought in after restorative measures and nine of them died. This high figure shows the danger of such a journey, which is nowadays almost never necessary.

### The Apparatus and Routine

The apparatus consists of six items and is accompanied by a nurse who has packed the bags and is familiar with the place of every detail in them. (1) A large box containing drugs, anaesthetics, antiseptics, mackintoshes, and ready sterilized bowls, douche-can, syringes, intravenous sets, and a canvas roll of instruments. (2) A small box containing sterile gowns, towels, gloves, and dressings for

minor operative procedures. (3) A theatre drum with contents as No. 2, but in sufficient quantity to carry out abdominal operation. (4) A crate of dried plasma, normal saline, and three or four pints of group O blood. It hoped soon to provide a constant stock of group O R negative blood and to carry it in a refrigerated container to avoid waste. (5) A bundle of blankets and hot-water bottles. These are scarcely ever needed, and now a often left behind. (6) A cylinder of oxygen and a B.L. mask. These have only rarely been needed.

A complete double set is available in case one set already in use or is being prepared.

A practitioner faced with an obstetric emergency telephones the Princess Mary Maternity Hospital and makes his request. If he asks for a particular consultant that consultant is communicated with first. Otherwise the consultants are telephoned in order of seniority until one is found available. It is thought to be essential for the efficient working of the service that a consultant should be quickly and immediately available, and it is no small price to the Newcastle obstetricians that even in the war years a call has not gone unanswered. By the time the consultant reaches the hospital the nurse is ready with the apparatus. Using his own car, he transports all to the patient's house and carries out any treatment necessary—often some hours' work. When the nurse returns she at once prepares the gear for use again. As soon as possible after a call the practitioner notifies the medical officer of health. The hospital makes a charge of one guinea for its services, and the consultant sends in an account in accordance with an agreed scale, depending on the services rendered, the mileage, and the time of day or night, together with a short description of the conditions found. In some instances the local authority may recover all or part of the fees from the patient, or the service may be used for a purely private case.

### Transport Difficulties

Mere distance is not such a difficulty as might be thought. There is a time lag of about twenty minutes getting the service into motion—taken in telephoning and reaching the hospital—so that even a case in the city is seldom reached in less than half an hour. At the other limit is Berwick where a time lag of two hours may be reckoned from receipt of the call until the patient is under treatment. It is the experience of those operating the service that much of the mortality is due to deaths within a few minutes of the emergency arising. Women who survive half an hour it is usually possible to save within a reasonably long time than this. On two occasions the squad failed to reach the patient. Once a car broke down, and a telephone call to the doctor showed that the emergency had passed. The second failure was due to a combination of an air raid, fog, and a very dark night with snow. Telephoned instructions were given to the doctor, and the next day the patient was brought into hospital, where she died. Great care must be used in taking exact instructions as to address, especially in the state of alarm that an obstetric emergency brings. Once a call came for Red Row. There are at least two villages in County Durham and two in Northumberland with this name. The fourth visited proved to be the right one. When nearing the objective small boys are easily the most efficient directors. At night take the local policeman aboard.

### The Conditions Treated

Among the 353 cases treated there were 41 miscarriages, 20 ante-partum conditions, 45 intra-partum, 231 immediate post-partum, 15 late post-partum, and one not pregnant. They will be discussed under these headings.

\*A paper read before the North of England Obstetrical and Gynaecological Society on June 6, 1947.

### Miscarriages

There were 41 cases, with two deaths, in this group. It is very rare for a woman to die of blood loss from miscarriage, and both the deaths in this series were due to sepsis, one within half an hour of arrival of the squad and one a fortnight later. Most of these women appeared to be too ill to bear transport to hospital. I have vivid recollections of a woman blanched from an incomplete abortion in the loft of a pitman's cottage from which the only exit was through a hatch and down a ladder. Every time her feet were lowered to get her down the ladder she fainted, remaining unconscious for a long time. Transfusion and digital emptying of the uterus were carried out in the loft and she made an excellent recovery.

### Ante-partum Conditions

The 20 cases (2 deaths) in the group were made up of 11 placenta praevia, 8 accidental haemorrhage, and 1 status eclampticus. Most of the haemorrhage cases received intravenous fluids and were then treated in various ways ranging from plugging of the vagina to caesarean section. Stored blood was not available until after 1940. Five of these cases were brought into hospital so that blood transfusion could be given, and it was in these five that the two deaths occurred. Since blood and plasma have been carried there has not been a single death in this group. Each of the two who died had intravenous glucose-saline, but the value of this was too temporary to protect her against an ambulance journey to hospital. They died shortly after admission, before blood transfusion could be established. There is no doubt that the pregnant woman who has lost blood must be saved an ambulance journey if at all possible, and this should be one of the prime objects of an obstetric emergency service. The patient with eclampsia had no further fits after the administration of morphine and intravenous magnesium sulphate. She was later safely delivered in hospital.

### Intra-partum Conditions

Among the 45 cases (6 deaths) in this group were 13 of "failed forceps" with three deaths. Apart from one due to face presentation and one due to foetal malformation the causes of failure were the usual ones of occipito-posterior lie, incompletely dilated os, and the administration of pituitary extract in the first stages of labour. Other intra-partum emergencies were: obstruction due to monstrosity (7 cases, 1 death); prolonged labour (8); impacted transverse lie (2); breech (3); failure to deliver the aftercoming head (3); impacted shoulder (1); prolapse of cord (1); contracted pelvis (2); retained second twin (2); failed version with arm, leg, and cord prolapsed (1); diabetic coma (1 case, 1 death); and intra-partum rupture of caesarean scar (1 case, 1 death). In four of these cases the cord was prolapsed. These mischances will arise so long as district midwifery continues. The bad old system of transporting these gravely ill and shocked women to hospital lessened their chances of subsequent recovery. The salvage of infant life in this group is small, but it would certainly have been less still if domiciliary treatment could not have been carried out.

### Immediate Post-partum Conditions

There were 231 cases, with 25 deaths. Fifteen patients were already dead when help arrived. It is in post-partum haemorrhage that the emergency service saves many lives and shows itself so dramatically necessary. Women blanched and moribund have been revived and restored to health. The lowest blood-pressure reading of a woman who recovered was 46/0, and systolic readings in the fifties are frequent. There were 186 cases of post-partum haemorrhage, divided into 88 with the placenta retained (8 deaths) and 98 after delivery of the placenta (10 deaths—3 associated with fibroids, 3 with heart disease, 6 with complete laceration of the perineum, and 1 with toxic goitre). There were, in addition to these cases of haemorrhage, 19 in which the placenta was retained without bleeding (2 deaths), 13 unexplained shock after delivery (1 death), 3 traumatic shock (1 death), 1 prolapse of cervix, 1 acute yellow atrophy of the liver (1 death), 4 incomplete rupture of the uterus (1 spontaneous), and 4 cases of acute inversion of the uterus (2 deaths).

With 18 deaths after post-partum haemorrhage in 186 cases it seems that some comment on the management of such

emergencies would not be out of place, for in many of the cases it was possible to surmise that had proper steps been taken earlier the emergency would never have arisen. The rarity of its occurrence in any one man's practice should not induce him to forget the grave condition that may arise if he does not act promptly when he has the first warning. In a great many instances a doctor was called in for post-partum haemorrhage by a midwife. All too often the subsequent treatment consisted of repeated and ever more forcible attempts to express the placenta by grasping the uterine fundus (so producing shock) and pushing downwards (so adding to it). Clot is repeatedly expressed, but the placenta does not follow, and in desperation oxytocics are given with the placenta still *in situ*. The bleeding ceases only when the woman is so exsanguinated and shocked that little blood is reaching the placental site. Should the placenta come away in the course of this treatment the woman is found to be white and collapsed.

In the normal delivery of the placenta the contracted uterus is used as a plunger to expel the placenta from the vault of the vagina or the lower uterine segment, and downward and backward pressure is correct; but no amount of downward and backward pressure will expel the placenta from the body of the uterus—it will merely produce shock by dragging on the broad ligaments and damaging the uterus and ovaries. The correct treatment is gentle massage of the uterus until it contracts, and if it fails to contract the accoucheur should proceed direct to the next step. If it contracts the fingers should be passed over the fundus and the organ squeezed as in squeezing a sponge. No pushing of the uterus downwards should be permitted unless and until the placenta separates.

If this manœuvre is ineffective it should not be repeated; without any delay the placenta should be extracted manually, for repetition produces the rapid summation of haemorrhage and shock. Failure to go boldly on to this step before the woman has lost condition is due to the pernicious teaching that manual removal of the placenta is "the most dangerous operation in obstetrics." It is a life-saving operation. It is easier and less dangerous than the application of forceps. If the indications for expression of the placenta are there the indications for manual removal are there. So soon as the former fails the latter should be done. The frightening teaching about the operation has led not only to avoidance of it but to timid and half-hearted attempts to carry it out. A placenta inside the uterus can never be reached by two fingers or even the half hand in the vagina. In a gravely ill woman an anaesthetic may be dispensed with, but usually it will be necessary. The whole hand is introduced, and by making the other hand outside the uterus do the greater part of the work the placenta is separated by the well-known manœuvre. The placenta is grasped and withdrawn. The hand immediately goes back into the uterus to make sure that every fragment of placental tissue has been removed.

Again teaching has been at fault in laying down that the hand should not be returned to the uterus once the placental site is laid bare. It should return as often as is necessary to be quite sure that not a fragment of placenta remains. With even a small piece of placenta left behind sepsis is almost inevitable. With an empty uterus it is rare. A douche is not necessary. If the readiness to perform forceps extraction of the child and the reluctance to perform manual removal of the placenta were reversed there would be many fewer calls on the emergency service. Seventy-seven placentae were removed manually in this series for post-partum haemorrhage. There were two deaths. One woman died six weeks later of heart disease and sepsis, and one failed to recover for no other reason than blood loss after having had the placenta removed. It does not appear that manual removal of the placenta is a dangerous operation. It is delay in its application that is perilous.

The four cases of acute inversion of the uterus are interesting. Two of these patients died before the squad arrived, a quarter and half an hour after the call was made. In one of the other two the uterus was immediately replaced and the patient made a good recovery; in the second it was replaced digitally four weeks later.

An unexplained and little-recorded type of case is that in which a woman is apparently dying with the placenta *in utero* though without bleeding and in which she recovers rapidly when

Table showing Types of Catastrophe met with

No.	Year	Diagnosis	Treatment	Remarks
1	1936	Retained placenta and P.P.H. Large uterine fibroid	Manual removal of placenta	Died three months later at operation for fibroid
2	1936	Impacted double monster	Delivery; intravenous saline; manual removal of placenta	Moribund on arrival
3	1938	Failed forceps; face presentation	Manual extraction of foetus and placenta	Died later of shock, haemorrhage, and sepsis
4	1938	Septic incomplete abortion	Oxygen	Moribund; died in half an hour
5	1938	xi-gravida; ruptured upper segment caesarean scar	Morphine; transport to hospital	Died half an hour after admission
6	1939	Incomplete abortion	Digital removal; blunt curettage	Died of sepsis a fortnight later
7	1939	Accidental haemorrhage	Intravenous saline (2 pts.; 1.14 litres); morphine; pituitary; transport to hospital	In hospital blood transfusion (1 pt.; 568 ml.); forceps delivery; died 5 hours after admission
8	1939	Accidental haemorrhage	Intravenous saline (2 pts.); morphine; rupture of membranes; transfer to hospital	In hospital blood transfusion. Died on delivery after three hours
9	1939	Post-partum shock after B.B.A.; submucous fibroid size grape-fruit	Transfer to hospital	Died 5 minutes after admission
10	1939	Moderate secondary P.P.H. 13 days after delivery; B.P. 80/44; removal of placental tissue; shock	Blood transfusion 12 oz. (340 ml.); morphine; lobeline	Died after three hours
11	1940	P.P.H. after delivery with placenta praevia	Intravenous saline (1½ pts.; 850 ml.); pituitary; transport to hospital	Died of blood loss 1½ hours after admission
12	1941	Failed forceps (twice) and pituitary extract shock	Blood transfusion; internal version and extraction	Died of shock soon after delivery; uterus wall intact
13	1942	P.P.H. and retained portion of placenta	Manual removal; transfer to hospital	Died 29 days later of mitral stenosis and sepsis
14	1942	P.P.H. from retained portion of placenta 12 hours after delivery	Removal of placental tissue; plasma (1 pt.); glucose-saline (1 pt.); transfer to hospital	Died 2 days later of acute yellow atrophy of the liver (necropsy)
15	1942	Shock and retained placenta	Plasma (1 pt.); manual removal of placenta	Died 19 hours later
16	1942	P.P.H. after twin; (1) normal delivery, (2) internal version after failed forceps; B.P. 76/40	Plasma (1 pt.); morphine; pituitary	Died ½ hour after arrival of squad
17	1943	P.P.H. after accidental haemorrhage	Blood (1 pt.); admitted to hospital 7 days later	Blood transfusion in hospital; died next day
18	1944	P.P.H. with retained placenta	Plasma (1 pt.); manual removal of placenta	Good immediate response, but died 3 hours later
19	1945	Post-partum shock and retained placenta after normal delivery of macerated foetus	Plasma (2 pts.); transfer to hospital	Blood transfusion in hospital but died after 5 hours
20	1946	Gangrene of vagina; general septic peritonitis 2 days after forceps delivery	Blood (4 pts.; 2.27 litres); penicillin	Died in another hospital
21	1946	Labour with diabetic coma	Transport to hospital	Died in coma day after admission
22	1946	Three calls: (1) failed forceps, os ½; (2) failed forceps; (3) shock due to rupture of vaginal vault into broad ligament	(1) morphine; (2) forceps delivery; (3) blood (2 pts.); transfer to hospital	Died as laparotomy about to be done

the placenta is removed. In a recent case the first glance at the woman made one think the squad had arrived too late, but she was found to have a pulse of 170, though this was impalpable at the wrist. Three pints (1.7 litres) of blood did not materially improve her condition. Five minutes after expression of the placenta she was chatting about housing and the weather and asking for food; she seemed to be almost a normal post-partum woman. Acute inversion of the uterus is analogous, for if the woman can survive the replacement of the organ the shock rapidly goes.

#### Late Post-partum Conditions

Fifteen calls came into this group, with 2 deaths. The cases comprised pulmonary embolism (2), macrocytic anaemia of pregnancy (1), puerperal sepsis (2 cases, 1 death), secondary post-partum haemorrhage from retained portions of placenta (9 cases, 1 death), and secondary post-partum haemorrhage from lacerations (1). It can be taken as axiomatic that in the absence of lacerations secondary post-partum haemorrhage means a retained piece of placenta.

#### Not Pregnant Case

There was one case of metrorrhagia haemorrhagica, blanched, fainting, and with no palpable pulse at the wrist, for which the service was used.

#### The Deaths

Of the 37 deaths 15 preceded the arrival of the squad. These 15 were made up of 2 with acute inversion of the uterus, 11 of post-partum haemorrhage, and 2 of post-partum shock. Eight were after normal delivery, 1 after twin, 1 after concealed accidental haemorrhage, 1 associated with shock after a difficult forceps delivery, and 1 after a difficult forceps delivery of a brow presentation in a woman with toxic goitre. The remaining 22 deaths occurred among 338 patients in whom treatment was possible. They are listed above as examples of the types of catastrophe which have been tackled. The acknowledged inadequacy of the nature and amount of intravenous infusions is noticeable in the earlier years. The introduction of an efficient blood bank was a gradual process, so that for some years blood was only available sporadically and then in small quantities. Now that there is always an available supply of blood, restorative measures can be undertaken with much more assurance of success.

#### Conclusion

It is a pity to end this account with a list of deaths. Rather should one say that out of 353 calls 338 patients were attended and 316 were saved. What proportion of these would have died without the attentions of the Emergency Service it is impossible to say, but many of them were so gravely ill that there can be little doubt that the number would have been large. In addition it is unquestioned that much subsequent ill-health was forestalled. There is little danger of the service degenerating into a replacement for hospital emergency admission, for the "nuisance value" of these cases in general practice is sufficient to deter practitioners from unnecessarily calling for domiciliary aid. With increased freedom of transport and release from some war conditions, greater demands are being made on the service (in the first half of 1947 the number of calls averaged two a week), but it is hoped that these demands will be met.

#### HASTINGS MEMORIAL AT WORCESTER

A memorial to Sir Charles Hastings, founder of the British Medical Association, was unveiled on Nov. 19 in the Board Room of Worcester Royal Infirmary, the room in which the Association was founded 115 years ago. The ceremony was performed by Dr. H. Guy Dain, Chairman of Council, who was accompanied by Mrs. Dain.

The memorial, which was erected by the Infirmary Committee of Management in 1943, is of oak, and bears the words carved and gilded, "To the memory of Sir Charles Hastings Doctor of Medicine and citizen of Worcester, who on July 18 1832, in this room, founded the Provincial Medical and Surgical Association, which later became the British Medical Association." Above it hangs an engraving of Sir Charles Hastings and below the inscription is the text of Sir Charles's address at the first meeting of the Provincial Medical and Surgical Association, with a short account of his life and work.

Dr. Dain said that the Provincial Medical and Surgical Association was founded in that room by some forty or fifty doctors from as far away as Bath, Bristol, Birmingham, Cheltenham, Warwick, Hereford, and elsewhere. With

most of the medical men of Worcester and the neighbouring towns, they met there at the invitation of Dr. Hastings. He came to the infirmary as a house-surgeon at the age of 18 without qualifications, went to Edinburgh and graduated, and returned to Worcester as a physician on the staff of the infirmary at the age of 24. He was a man of enormous energy and originality. He started *The Midland Medical and Surgical Reporter and Topographical and Statistical Journal*. In the final issue of this journal he wrote: "A wish has been warmly expressed and widely circulated that the members of the profession residing in the provinces should unite themselves into an association, friendly and scientific." In the prospectus of the Association the first four objects set out were the collection of useful information through case reports; the increase of knowledge of the medical topography of England through statistical and other inquiries; the investigation of endemic and epidemic diseases; and the advancement of medico-legal science. The fifth object was: maintenance of the honour and respectability of the profession generally, in the provinces, by promoting friendly intercourse and free communication of its members, and by establishing the harmony and good will which ought ever to characterize a liberal profession.

At the first historic meeting in this room Dr. Edward Johnstone, of Birmingham, was elected the first President, and Dr. Hastings and Mr. Sheppard were appointed secretaries.

The Association Hastings founded extended its scope and changed its name to the British Medical Association. To-day the B.M.A. had branches and daughter associations throughout the Empire and all over the world, and a membership of over 57,000.

Charles Hastings was one of those rare individuals who saw clearly where there was need for a great step forward, and he had the energy, tact, and persistence to secure that that step forward was taken. To-day the ideals of Hastings and the early pioneers were unchanged. The first aim of the B.M.A. was still "to promote the medical and allied sciences, and to maintain the honour and interests of the medical profession." In its present negotiations with the Government on the matter of Health Services the Association was maintaining the principles Charles Hastings laid down.

## THE HOUSE OF TO-MORROW

[FROM A CORRESPONDENT]

At the Building Exhibition at Olympia, which will remain open until December 4, the Ministry of Health has put forward some new ideas on the urban house of the future. The plans are in the blue-print stage, but if they survive the criticism of architects, builders, and others interested in the housing of the people they will be passed on to local authorities.

In this country the small house is traditionally of two stories. There are, of course, innumerable houses in towns with three or four or more stories, and in the country plenty of cottages and bungalows with only one, but the general pattern of working-class housing has been "an upstairs and a downstairs." The Ministry shows a model of a terrace of three-story houses with two rooms at each story intended for the accommodation of a family of five or—with rather more space though not more rooms—of seven. A terrace of ten three-story houses with no break between them is not aesthetically pleasing. A frontage with eight doors, with another door round the corner at each end of the terrace, is not perhaps the happiest arrangement, and the narrowness of the houses is emphasized by their height. On the other hand, this form of construction contrives to give rooms as large as possible, and there is a terrace roof which perhaps compensates for the additional stairs. This type of house is in a sense a reply to the garden city or suburb, which demands space and therefore cannot be planned near to the centre of large cities. These houses occupy the minimum of ground space and therefore may be built within easy distance of the business area.

Another design put forward by the Ministry consists of four-story combined maisonettes and flats, with access balconies. The maisonettes are intended to meet the needs of people who want to combine the convenience of a flat with the freedom of a house. They are of four or three rooms, and the flats in the same block are two-roomed. This is another departure from the stereotyped council house.

The encouraging thing about these developments is the attention which architects are paying to the small individual house and particularly to the arrangement of the working-class kitchen and living-room. Rural families, it is said, prefer the kitchen and living-room to be combined, while industrial families like to have their meals in the kitchen. The families of city workers mostly prefer to keep the kitchen for cooking and laundry only. Full-scale rooms show how each of these preferences may be met with a minimum of labour and with the greatest saving of space.

The Government exhibit, with which the Department of Scientific and Industrial Research is associated, is only a small part of what the building industry is presenting in the vast spaces of Olympia. With new methods of plastering, partition walls, insulated flooring, warming and cooking systems, and new arrangements in glass and timber and steel and aluminium, the shape of the house to come seems very desirable.

## THE LASKER GROUP AWARD, 1947 AMERICAN HONOUR FOR BRITAIN

The illustration below shows Dr. George Baehr (centre), chairman of the Lasker Awards Committee of the American Public Health Association and president of the New York Academy of Medicine, presenting one of the Lasker Group Awards to Sir Wilson Jameson, Chief Medical Officer of the British

[Press Association]

Ministry of Health, with Dr. Lowell J. Reed, of Johns Hopkins University, looking on. Sir Wilson accepted the award on behalf of the British Ministries of Food and Health for the wartime programme of food distribution in Britain.

Dr. Reed accepted a similar award for the U.S. Committee on Joint Causes of Death, of which he is chairman, for uniform

classification of statistical data on death and disease, facilitating the interchange of medical information between all countries of the world. Dr. Reed is vice-president of the Baltimore University.

The presentations were made at the 75th annual meeting of the American Public Health Association on Oct. 9, at Atlantic City.

## Reports of Societies

### BRACHIAL NEURALGIA

At a meeting of the Physical Medicine Section of the Royal Society of Medicine on Nov. 12, Dr. W. S. TEGNER, president of the Section, was in the chair.

Dr. W. RUSSELL BRAIN opened a discussion on brachial neuralgia, which he defined for this purpose as pain of nervous origin in the upper limb. Until recently the commonest cause was held to be brachial neuritis. So far as he knew no pathologist had ever observed a simple neuritis of the brachial plexus. The causes of brachial neuralgia were many and varied. Cervical rib held the field for a long time, until it was shown that symptoms might be present without the rib and absent with the rib. The way of wisdom was to make a frank confession of ignorance and to maintain a healthy scepticism towards the many theories put forward.

Dr. Brain said that with seventh cervical root or spinal nerve irritation there might be pain and tenderness in the neck and shoulder, in the scapular and pectoral region, and also along the dorsal aspects of the arm, forearm, and middle finger. It might be expected that all contiguous areas of the dermatome would suffer equally, but most lesions were partial ones which did not affect all forms of sensibility equally nor all areas to the same extent. Motor symptoms were less prominent than sensory, and muscular weakness was usually only slight. Congenital abnormalities were quite common in cervical or spinal nerve manifestations and played a part indirectly in the production of other symptoms. He described the clinical picture of herniated cervical intervertebral disk. The patient usually complained of considerable pain in the neck, which might develop quite suddenly, and he might be compelled to lie on his back because lying on either side increased the pain in the shoulder and arm. Occasionally a herniated cervical intervertebral disk would compress the spinal cord. Among major abnormalities found in this area Dr. Brain mentioned a fibrous band from the seventh cervical transverse process, abnormal shape or unusual height of the first rib, and abnormal origin and insertion of scalenus anticus. More than one of these anomalies might be present. It had been suggested that scalenus anticus spasm or hypertrophy alone might be responsible for symptoms. Dr. Brain also mentioned the costoclavicular syndrome, and illustrated one case with three cervical ribs. A spontaneous form of compression neuritis of the median nerve had only recently been described and recognized, though for some time it had been known that local injury of bone in the region of the wrist-joint might cause compression of the nerve.

Dr. Brain mentioned a condition occurring frequently among middle-aged or elderly women who had done a good deal of housework. They complained of tingling and pain in the region of the median nerve, associated with weakness and wasting of the muscles of the thenar eminence. The correct treatment if the condition was early and there was no muscular wasting was by rest and physiotherapy, provided they were able to give up manual work afterwards; if they were not able to do so they would almost certainly relapse. In cases which had gone on to muscular wasting and sensory loss surgical treatment was indicated, and those operated on had done exceedingly well. One curious manifestation during convalescence in some of these cases was the development to a mild extent of a Raynaud-like syndrome in the fingers, particularly during the first winter after the operation.

### Surgical Experience

Mr. D. W. C. NORTHFIELD reviewed a number of cases with pain in the arm as the presenting symptom. The first group consisted of cases in which the trouble was due to pressure or

traction on part of the brachial plexus. There were 27 cases in this group, in 6 of which the symptoms were bilateral. Females predominated, and the commonest age period was between 30 and 50. In at least half the cases x-ray examination showed the presence of at least a rudimentary cervical rib. On the whole the pain followed the distribution of the first thoracic nerve. At night some patients were more comfortable lying on the affected limb, and others lying on the back. In 18 cases there were complaints of circulatory changes, and in 19 the patients had noticed some disturbance of muscles or actual muscular wasting. Wasting and weakness of the intrinsic muscles of the hand and of the lateral part of the thenar eminence were frequent. Some impairment of sensation was noticed in 13 of the cases. The operation was primarily one of exploration. Even when x rays showed a cervical rib he did not start out with the idea of removing it, but decided the correct procedure in the light of the findings at operation.

His own feeling was that in cases which demanded operation the division of the scalenus anticus probably offered a good prospect of a satisfactory result. He thought also that nerve-pressure effects were due not so much to the nerve being pressed on or riding across the first rib as to compression of the subclavian artery, the pressure in the artery being transmitted to the nerve. It was this transmitted pressure rather than the rib itself which caused symptoms to appear.

A number of cases of thickening of the ulnar nerve at the elbow were mentioned. In 26 cases, predominantly male, the condition was bilateral in 3. There had been antecedent injury to the elbow, ranging from minor bruising to severe fracture, in 11. In this condition there might be an occupational factor: 2 of the patients were violinists, and 8 were labourers on heavy work. In 19 of the 26 cases pain was present, felt sharply around the elbow and radiating downwards to the little finger. In some of the cases wasting of the small muscles of the hand had been observed by the patient. Transplantation was the operation of choice. The nerve itself was found in some cases thickened to twice the normal size.

Ten cases of cervical intravertebral disk were described, in all but one of which protrusion was found. It was possible that the protrusion eventually became absorbed, but during the process it might cause scarring and thickening of the membrane. In the 9 proved cases the protrusion occurred between the fifth and sixth cervical vertebrae in 4, between the sixth and seventh in 2, and in the remaining 3 between the second and third, the third and fourth, and the fourth and fifth cervical vertebrae.

## DIET AND THE NATION'S HEALTH

### DEBATE BY THE HUNTERIAN SOCIETY

A debate was staged by the Hunterian Society at the Apothecaries Hall, London, on Nov. 17. Mr. ALEX. E. ROCHE presided over an attendance of between three and four hundred. The supporters of the motion "That our present diet is undermining the health of the nation" were two medical men and the opposers two doctors of science.

### The Missing Calories

Dr. FRANKLIN BICKNELL took the affirmative. Man required 3,000 calories a day. That was the figure agreed by the British Medical Association in 1932 and by the Ministry of Health in 1933, while the League of Nations Committee admitted a higher figure. From his rations, according to a statement by Dr. Summerskill (on Oct. 29), an adult British citizen obtained 1,530 calories. Since then potatoes had come on the ration, and, with an adjustment for bad potatoes, added 139 to the daily figure. How was the gap between 1,669 and 3,000 to be bridged? Unrationed foods such as offal and meat pies were the not with certainty obtainable, and fish and vegetables were the principal unrationed foods left. A Ministry of Food survey last July mentioned 2,237 calories as the average consumption per capita in a working-class family; this was before rationing and the cuts in cheese and sugar. Restaurant and canteen meals were cited as meeting the deficiency, but "meat out" per capita accounted for only 1½ main meals and 2½ small meals a week, and a main meal might be only about 350 calories. If anyone was surprised to be told that his calorie consumption now was only half what it was before the war:

should bear in mind that a meal of boiled fish, boiled potatoes, and bread and cheese would furnish about 300 calories, whereas the same fish and potatoes fried, and with butter on the bread, would add up to 1,000 calories. That was the explanation—absence of fat. The housewife, who had small chance of eating out, was told that she could have the redundant rations of her children; but those who knew the consuming capacity of a growing boy would be aware that there was not much to spare from that source.

How was it, then, that we were not always hungry and not very thin, and why did not the mortality and morbidity rates go up? Sir John Boyd Orr had said that the loss of genuine hunger was one of the earliest signs of malnutrition. Moreover, with an inadequate diet a person did not of necessity lose weight. The body conserved its resources by the simple process of lessening productivity. In explanation of the mortality figures he pointed to the advances in chemotherapy and in surgery during the last eight years, the advances also in maternal and child welfare and in diphtheria prophylaxis. It might have been expected that there would have been a much greater fall in mortality rates had not these advances been largely nullified by the inadequate diet. As for morbidity, the notifications of tuberculosis had gone up, eye diseases and skin diseases were more common, convalescence was longer. He even attributed some of the 'decay' in morals to the lassitude induced by inadequate feeding. Fatigue was one of the first evidences of deficiency.

#### Opposing Views

Sir JACK DRUMMOND declared that there was no objective evidence showing with clarity and precision that the nation was less well nourished than it had been in 1938. He agreed that the calorie situation was important. His old master, Sir William Bayliss, used to say, "Take care of the calories and the rest will take care of themselves." There was much misunderstanding on this point to-day. It was very easy to misinterpret the figure of 2,700 calories which the Government had recently announced. The population included young children and adults, sedentary workers, light-manual workers, heavy workers, and the requirements spread themselves over a very wide range from those of the infant to those, say, of the forester engaged in heavy labour in cold weather, whose calories might perhaps reach 5,000 a day.

Before the war there was maldistribution of food, resulting in the undernourishment of about one-third of the population, and as the food supplies were adequate for the whole population it meant that the other two-thirds were in a sense overfed. No one denied that present restrictions were grievous, but at least the war had equalized distribution and imposed equality of sacrifice. Since 1941 a close check had been kept on the nutritional value of food. No one liked the wartime diet, but it was all that could be obtained, and an analysis of it showed that nutritionally it was better than the pre-war diet.

As to the results, there was no more sensitive indication of health than vital statistics. The general death rate, the infant and maternal mortality rates, the death rate from tuberculosis had all improved since 1940. The incidence of anaemia in women and of rickets in children had declined; the rate of growth of children had increased. He spoke as one who had seen starvation in several Western European countries after D-day, and "We are not up against anything like that, thank God!" Bread and potato rationing had made the position grave, but he was not as apprehensive as Dr. Bicknell. Provided there was no major dietary deficiency, a simple calorie shortage was not a very serious matter. Inevitably it would reduce production. The present calorie level would only barely meet the estimated requirements, and this must mean that the heavy worker and the adolescent, whose energy requirements were high, would go hungry and their productive capacity would fall. That had happened in France and everywhere else, but it was not an undermining of health. These people might for a few months produce less than expected, but they would even up as things got better. While the present food situation was serious—far more serious than they ever thought it would be six months ago—there was no reason for believing that the diet, plain, unattractive, and monotonous as it was, would undermine health. In no country was the food so well distributed. In France, or even in Eire, the rich could feed as

well as they wanted, and the poor could go to the wall. In this country "we are having a devil of a time, but at least we are all more or less suffering together. I challenge those who support this motion to bring forward any clear objective evidence—not hearsay, not merely subjective impressions—that the health of the nation has been impaired."

#### Views of a General Practitioner

Dr. KENNETH MCFADYEAN, as a general practitioner, spoke in favour of the proposition. Someone had written in an editorial that the impressions of medical practitioners were founded on general complaints by patients of fatigue, lassitude, and an "out-of-sorts" feeling, but, the editorial went on, "no one has brought forward evidence to show that they are attributable directly or indirectly to lack of food." But what evidence was wanted? At least one general practitioner had drawn attention to the increasing number of cases of hypochromic anaemia, a condition in which frequently the only symptom was fatigue and there were no signs until the victim collapsed on the factory floor, but it had also been shown that the addition of protein to the ordinary rations banished hypochromic anaemia. It was all very well to quote figures concerning children, but what about the people between 20 and 50, the workers who had to maintain themselves and the children and the aged people? It was in the third to the fifth decade that hypochromic anaemia and other dietary deficiencies asserted themselves. How many women succeeded in nursing their babies for longer than four weeks? What about the increase in infantile gastro-enteritis? In a recent series of cases at Great Ormond Street, of 167 infants with gastro-enteritis admitted only one had been fed naturally. It took the mother all her time to feed herself, let alone her infant. He also referred to the increased prevalence of skin diseases in the adult population—impetigo and sycosis barbae. The latter condition formerly was not seen once in five years by a practitioner, now he saw any number of such cases. They were due to the absence of fatty acids to protect the skin. Ophthalmologists spoke of an increasing number of inflammatory conditions in the eye and of patches of choroid degeneration in young adults. Chronic rheumatic infections were increasing. The objective evidence "stuck out a mile." An army was expected to march on its stomach, but those who ordered our rations to-day apparently expected us to fly on air, blowing out gases from our empty exhausts, belching forth exports from empty stomachs. The general practitioner might not be a statistician, but there was knowledge and common sense behind his observation.

#### The Verdict from Statistics

Mr. MAGNUS PYKE said that nutritional health depended on the provision of a properly balanced diet, with proteins, fats, carbohydrates, and the rest, which had been demonstrated by experiment to be needed for the proper function of the body. There were many different patterns of diet. In no country did the official rations provide the sole food for the subsistence of the population. In addition to the strict rations there were unrationed meals distributed through restaurants and canteens, special rations for invalids, school meals, food from allotments, and certain unrationed articles of food such as fish, rabbits, and vegetables. If the health of the nation were being undermined it would show itself in the mortality tables, but the fall in that respect, which had been a feature of public health during the present generation, had continued during the war and into the post-war period. He had figures also showing the steady increase in the height and weight of children. The average weight of a number of 12-year-old children in Liverpool in 1935 was 33.4 kg., and in 1946 for a similar group it was just upon 35 kg. It was notoriously difficult to assess the nutritional state of the adult and to measure precisely whether his health was or was not undermined by diet. The biological system of man was infinitely adaptable to circumstances. But tuberculosis was closely related to nutrition, and if shortage of food were undermining the health the incidence of tuberculosis would have shown a marked increase, which was not the case. Tuberculosis mortality had fallen steadily since 1942. Old people, who had perhaps the greatest difficulty in obtaining a full diet, had shown a decreasing death rate in every quinquennium since 1926-30, but the greatest decrease was

shown in the quinquennium 1941-5. Conditions like obesity, alcoholism, high blood pressure had had less chance to operate.

Even when the full rigours of reduction of supplies came into force in 1948 the consumption level of 2,700 calories would still be sufficient to cover the population. That figure was made up as to 72% of calories distributed as rations, the remainder was derived from the diverse avenues of distribution he had already named. The average for each school meal was 349 calories.

### General Discussion

The PRESIDENT, in throwing open the meeting to discussion, said that it was not merely a question of the value of the diet, but of obtaining it. Many of the calories in the ration must be spent in queueing to get it. Dr. NEVIL LAYTON said that people were apt to compare European countries with Britain, to the latter's advantage, but actually, although the ration in Norway, Holland, and Czechoslovakia might not be generous, the fats were approximately double the amount obtainable in Great Britain. He had come across cases of nutritional oedema in this country. Dr. G. E. BREEN asked for the basis of the assertion that, before the war, one-third of the population was underfed. Assuming that the unemployed were underfed, they and their dependants would not have amounted to more than four-and-a-half millions, or 10% of the population. Surely the lowered rates of mortality or morbidity could justly be ascribed to the sulphonamides and penicillin, to diphtheria immunization, and to other advances which had made their appearance during the last ten years—one of the most revolutionary periods in the history of medicine. He complained of a certain presumption and arrogance on the part of professional nutritionists. He wondered how their bold statements would look in thirty years' time.

Mr. DICKSON WRIGHT came down heavily against the proposition that the present diet was undermining health. In the present company he could detect no signs of malnutrition; they gave the appearance of a very well fed assembly. Some of the arguments used in support of the proposition had been trivial. The occurrence of diseases like impetigo had been cited as evidence of malnutrition. Yet it was only a short time ago that a gentleman from the United States, that land of plenty, arrived at London Airport and was found to be suffering from impetigo, and was not allowed to remain but was sent back by the next aeroplane to his own country. If we were faced with real food deficiency, what about the millions we spent on alcoholic liquor and on tobacco? What food those millions would purchase! It had even been suggested by the principal speaker in favour of the proposition that our present diet was the cause of the decline in morals. It made him imagine a co-respondent in the divorce court begging the judge not to be too hard upon him because he had been underfed!

The openers made brief replies. Dr. BICKNELL begged for serious decision on the part of the meeting—a decision, he said, the effect of which would go beyond that assembly. Sir JACK DRUMMOND claimed that no concrete facts had been brought forward to support the view that there had been deterioration of health as a result of diet. All the objective evidence went to show that the health of the nation was not undermined. Indefinite statements about skin conditions, gastro-enteritis, chronic rheumatism, and the like, being attributable to diet should not be taken too seriously. He recalled that in 1940 the Parliamentary Secretary to the Ministry of Food announced that on the suggestion of the medical advisers to the Ministry it had been determined to add a proportion of calcium to flour. Within a week the Ministry received protests, which continued for months afterwards, declaring that the calcium in the loaf was responsible for all manner of ills. Medical men claimed that their patients were suffering as a result. Some of these medical men bore well-known names. Yet in actual fact, owing to a hold-up of supply, no calcium was added to flour for eighteen months after the announcement, and after it was added there were no complaints.

The question "That our present diet is undermining the health of the nation" was put to a show of hands, and the vote of the meeting was in the affirmative by about three to one.

Mr. MORTIMER WOOLF, in proposing a vote of thanks, said that after this array of statistics and arguments he still thought the best dietetic advice was given from the music-hall stage, "A little of what you fancy does you good."

### Penicillin Blood Levels

SIR,—We have just finished investigations concerning the excretion and the role of penicillin in the organism, and we present here a preliminary report. Our first results, which will be published in detail elsewhere (*Acta Medica Hungarica*, Budapest) can be summed up as follows.

The investigations were carried out in order to raise the serum-penicillin level and to diminish its excretion. We found that the hippuric-acid content of the blood and the urine can be easily and continuously increased by means of vegetable protein meals, especially by oatmeal. The troublesome para-aminohippuric-acid drop infusion, suggested by Beyer and his collaborators, can be avoided thus. The serum-penicillin level can be considerably raised by an oatmeal diet, and its excretion can be reduced to such a degree that, six hours after a single injection of 60,000 units, a powerful bacteriostatic effect is still demonstrable in the serum. The quantity of the penicillin and the number of the injections can be reduced thus. A similar effect could be demonstrated by the administration of a single dose of amidopyrine, 0.3 g. per os. If this dose was repeated two-hourly, the bacteriostatic power of the serum could be maintained as long as six hours (20,000 i.u. of penicillin being administered before).

Clinical symptoms led us to assume deficiencies in some vitamins during prolonged penicillin treatment. This is particularly striking in the case of vitamin C. Considering the well-known role of vitamin C in infections, this relation can be of importance in future penicillin treatment and in the explanation of the bacteriostatic effect of the penicillin.

In connexion with sensitization phenomena as the result of penicillin treatment, it was possible to produce with the serum of one of our patients a positive Prausnitz-Küstner reaction (passive transfer of antibodies) after the administration of 21,000,000 units of penicillin. It was also possible to demonstrate changes in the appearance of different cutaneous tests—e.g., von Pirquet—during the penicillin treatment—i.e., the positive von Pirquet test became weaker after a few weeks' treatment or changed into a negative one.

Bacteriological studies revealed that in contrast to data already published in the *Journal* (Ellinger and Shattock, 1946), the bacterial flora of the alimentary tract remains substantially unchanged during the penicillin treatment. Haemolytic streptococci disappear from the flora of the mouth and throat, but other streptococci and staphylococci, as well as penicillin-insensitive bacilli, continue to be present in unaltered quantities. The intestinal flora remains likewise unchanged.

In view of the fact that great quantities of penicillin—excreted in the saliva and in the bile, the eventual changes of the pH of the saliva and the digestive potency of the intestinal enzymes were investigated after penicillin treatment. The pH of the saliva diminished in every case during the treatment. The diastase values (Wohlgemuth) of the faeces have decreased similarly. These contributions may be of importance in the nutrition of patients during penicillin treatment.

Investigations into the diffusion properties of penicillin reveal the fact that 0.5 i.u. of penicillin does not pierce a layer of fibrin 3 mm. in depth prepared from pure thrombin solution and crystallized fibrinogen solution *in vitro*, but it will be adsorbed by it, since 0.5 ml. of precipitated fibrinogen adsorbs less than 1 but more than 0.5 i.u. of penicillin. This adsorption can be inhibited and adsorbed penicillin can be eluted again by adding a solution of sodium dehydrocholicum.

Difficulties encountered in treating the heart-failure symptoms of penicillin-treated cases of endocarditis led us to investigate the possible interference of penicillin and digitalis. Electrocardiographic changes in penicillin-treated pigeons and their altered response to pure digitoxin show that prolonged penicillin treatment has an influence perhaps directly on the sinus node. There is no real interference between the two drugs, but subclinical sensitization with penicillin and lessening of the B<sub>1</sub>-vitamin content of the organism may cause an increase of lipoids, especially of cholesterol. The latter is apt to attack one part of the digitalis glycoside.

On the early-morning  
shift, during  
blasting operations . . .

Casualties in circumstances of this sort  
frequently call for ophthalmic surgery.

One of the most suitable anaesthetics in use for eye  
surgery is Soluble Thiopentone, given as a total anaes-  
thetic by intravenous injection. The eyes remain fixed  
and after-sickness is negligible.

Soluble Thiopentone has other important advan-  
tages — ease of administration, ease of portability,  
quiet respiration, non-inflammability. It is usually  
given intravenously, but may be administered *per*  
*rectum* as a basal anaesthetic.

Soluble Thiopentone is a mixture of 100 parts by  
weight of the mono-sodium derivative of 5-ethyl-5-  
(1-methylbutyl)-thiobarbituric acid, and 6 parts by  
weight of exsiccated sodium carbonate.

# C is significant in illness this winter

Even for those in normal health, the winter diet may yield only a bare sufficiency of vitamin C. In face of acute illness particularly when fever is involved, the need for the vitamin always rises sharply and, unless this need is met, the whole course and convalescence of the illness is disturbed. Additional vitamin C is best given in the form of 'Celin' Tablets—two, three or more daily. Each 'Celin' Tablet contains fifty milligrams of ascorbic acid (pure vitamin C). An assured level of ascorbic acid is also of particular importance in the process of wound healing. 'Celin' Tablets should therefore be given routinely before and after operation.

(50 mg. ascorbic acid). Bottles of 25, 100, 500 and 1,000. Also available in ampoules containing 100 mg. ascorbic acid per cc. in boxes of 6, 12, and 50 x 1 cc.  
\*Dispensing size only.

GLAXO LABORATORIES LTD, GREENFORD, MIDDLESEX. BYRON 3171

## THE LESSON OF THE OYSTER

Slowly the pearl within the oyster is built up until the growth assumes abnormal dimensions. Similarly the gall-stone in the gall-bladder develops from stagnation of bile; concentration follows and precipitation of cholesterol is the result.

Veracolate brings to the therapy of functional gall-bladder disorders the two most effective substances for keeping the bile freely flowing: sodium salts of taurocholic and glycocholic acids.

## VERACOLATE

WILLIAM R. WARNER & CO. LTD.,  
Power Road, London, W. 4.

The reduced glutathione level in the blood rises after a single injection of 20,000 i.u. of penicillin and becomes constantly higher during prolonged treatment. This fact may be of importance to the mode of action of penicillin, glutathione being composed of glutamic acid, cysteine, and glycocoll (glycine). It is possible, therefore, that this increased amount of glutathione has a similar effect upon the glutamic acid of bacteria, as sulphonamides have against para-aminobenzoic acid.

Detailed communications in connexion with this work appeared or will be published in the *Orvosok Lapja* and *Magyar Belorvosi Archivum*, both in Budapest, *Acta Medica Scandinavica*, Stockholm, and *Schweizerische Medizinische Wochenschrift*, Basle.—We are, etc.,

## Penicillin for Infected Hands

SIR.—In his letter on the use of penicillin in the treatment of infected fingers (Nov. 1, p. 707) Dr. E. Jaffe suggests that prophylactic penicillin may be used with some success in very early cases to abort the condition. I wonder if this is not rather a precarious statement to make in view of the possible severe consequences. I have recently seen two cases of palmar-space infection which appear to illustrate the risks which may be involved by conservative treatment. It is because of the extreme difficulty of diagnosing the presence or otherwise of pus in these cases that I wondered if Dr. Jaffe or anyone else had experienced any similar recurrences in very early cases of pulp infection.

The first, a young man, reported sick with a diffuse swelling of the palm of his left hand of twelve hours' duration. The swelling was compatible with an early inflammation of the middle palmar space, but was only tender to moderate pressure. He had slept well during the night and had experienced no pain. He had no fever, lymphangitis, or lymphadenitis. He was sent to hospital immediately, where he received a course of 750,000 units of penicillin given in equal three-hourly doses over a period of ninety hours. There was no surgical interference. He was discharged two days later symptom-free and with full function of the hand.

After seventeen days he had six carious teeth extracted. Twenty-four hours later he presented with a similar swelling on his hand, which was throbbing and acutely painful. He was running a slight temperature. He was returned to hospital, where a good result was obtained with surgical drainage of the palmar space followed by a further course of penicillin.

The second case, also a young man, presented with a painless swelling of the palm of his right hand of approximately sixteen hours' duration. The swelling suggested an inflammation of the middle palmar space, but it was tender on deep palpation only. There was no constitutional disturbance. He was sent to hospital, where he received exactly the same conservative treatment as the previous case. On discharge he was symptom-free and had full function of the hand. Fourteen days later he caught his hand in a trapdoor, resulting in mild bruising. The skin was not broken, but the same evening his hand became intensely painful and swollen on the palmar side. When I saw him at midnight (fourteen hours after injury) he presented the clinical picture of very acute middle palmar-space infection. He was returned to hospital, where the condition was successfully treated with surgical drainage followed by a prolonged course of penicillin. The final result was excellent. (There had been no bony injury.)

It would appear probable that despite the short duration of the original symptoms a small pocket of pus had formed in both cases, that the first course of penicillin had been sufficient to sterilize this pus and render it quiescent for a relatively long period, and that reinfection of the focus was brought about in the first case by a transient bacteraemia and in the second by moderate trauma. These cases demonstrate the results which may follow neglect of the simple rule that chemotherapy should never be used in cases of suppuration in the absence of adequate surgical drainage. But, with this in mind, they further show the extreme difficulty of diagnosing the presence or absence of pus in very early cases. The severity of the second infection and the increased loss of man-hours involved, despite clinically adequate treatment with penicillin, demonstrate the dire results which may follow misjudgment in the case of palmar-space

infections. I wondered at the time whether more intensive penicillin therapy in the first instance, despite the clinical cure, would have prevented the recurrences of infection.

It would be interesting to know if others have had similar experience with fascial-space infections, and whether the earlier appearance of pain in pulp infections does in fact increase the chances of successfully instituting penicillin therapy before the actual formation of pus.—I am, etc.,

Leamington Spa.

A. GORDON DINGLEY.

## British Food Resources and Requirements

SIR.—According to the report of the conference arranged by the Nutrition Society (Nov. 15, p. 786) I said that the agreement of estimates of food supplied and consumed "was as good as could be expected in view of the low degree of accuracy of dietary surveys." What I actually said was that the agreement was better than could be expected in view of the inaccuracy of estimates of the amount of food imported and produced in the country. The point is important, for if we were getting an average 2,800 calories per head, as reckoned from estimates of imports and production, there would be no need to worry about calories.—I am, etc.,

London, E.1.

J. R. MARRACK.

## Food Cuts and Vitamins

SIR.—Your interesting and valuable leading article entitled "Food Cuts and Vitamins" (Nov. 1, p. 696) calls for comment on three separate matters.

First, I conceive it a pity to refer to "the new standards of the National Research Council of the U.S.A." That body, in both editions of its reports and through the mouths of several of its members on a number of occasions, has consistently asserted that it was not laying down dietary standards. It has called its estimates, and given convincing reasons for so doing, "Recommended Dietary Allowances." These allowances, unlike any estimates of requirements, are intended to allow for at least part of the losses that occur during processing, transport, storage, and cooking, and are also meant to "take up the slack" for those individuals at one end of the scale of requirements for any given nutrient. Nothing is more striking in such recent publications as the invaluable monograph of Widdowson on school-children's diets than the extraordinarily wide range of intakes, and these strongly suggest a correspondingly wide range of requirements. The American recommendations are intended to take care of the higher of these requirements and so would obviously supply more than is necessary to those with lower requirements. They cannot, therefore, be themselves regarded as figures for requirements, and are, as their promulgators make clear, simply recommended allowances.

Secondly, I am a little surprised that your comments on riboflavin intake ignore one of the most striking and in some ways entertaining facts revealed by wartime studies of diet. In this country, at any rate, beer and tea can provide an appreciable part of the daily intake of riboflavin and also of nicotinic acid; for the more intemperate they may even provide major contributions.

Finally, there seems to me a serious error in your parenthetical observation that "as is now the accepted practice in this country, the vitamin-A value of  $\beta$ -carotene is taken as 1 i.u. per 0.6  $\mu$ g." Dr. Leslie Harris's article (p. 681), to which you make specific reference in your leader, says quite clearly "carotene is only about one-half or one-third as well utilized by the animal body compared with an equal amount of vitamin A." Without going into elaborate arithmetical details it must suffice here to say that although 0.6  $\mu$ g. of pure  $\beta$ -carotene has, by definition, the activity of 1 i.u. of vitamin A, this refers to comparative tests under carefully standardized conditions of vitamin-A-depleted albino or piebald rats. It is universally accepted that the efficiency of converting carotene to vitamin A is much less for man and other domestic animals receiving mixed diets and not obviously short of vitamin A. There is some evidence that the efficiency of conversion diminishes with increasing levels of vitamin A in the diet. If that is so, any figure for equivalence of the vitamin and the provitamin can be only a rough approximation. Experts in this country and the United States seem, on this matter at any rate, to be largely in agreement that the only safe assumption for the

nutritionist to make is that 2  $\mu\text{g.}$  of carotene is required to supply in an ordinary diet the equivalent of 1 i.u. of vitamin A. This, incidentally, is a highly practical question and not an academic matter of figure manipulation. If a daily intake of 2,500 i.u. is required and 500 of these are supplied as preformed vitamin A, the amount of carotene needed in addition will be either 1,200  $\mu\text{g.}$  or 4,000  $\mu\text{g.}$  per day, according as we take 0.6  $\mu\text{g.}$  or 2  $\mu\text{g.}$  to be equivalent to 1 i.u. This, according to "Nutritive Values of War-Time Foods," represents the difference between 12 and 40 g. of fresh summer carrots or between 3 and 10 oz. (85 and 284 ml.) of liquid summer milk.

Incidentally, the Medical Research Council War Memorandum No. 14, to which I refer above, contained on p. 4 of the original edition an unfortunate printer's error, whereby it is stated that 1 i.u. has, by definition, the potency of 0.06  $\mu\text{g.}$  of  $\beta$ -carotene; this was subsequently corrected by an erratum slip to the correct figure of 0.6. I would, however, again emphasize that this equivalence is a matter of definition applying to certain specified laboratory conditions and that for practical purposes the biological activity of carotene so defined has to be divided by 3 or 4.—I am, etc.,

London, N.W.3.

A. L. BACHARACH.

### Duodenal Ulcer and Priority Foods

SIR,—I think Dr. A. H. Morley (Nov. 8, p. 745) is a little hard on his patients. While the milk ration for children remains so small, who knows what pressure is brought to bear on father to cultivate his gastric symptoms? I believe that gastric sufferers are given milk and eggs as it is assumed they are unable to eat meat. If the issue of milk certificates automatically cancelled meat and bacon rations it would cause no hardship to genuine sufferers and discourage others from renewing priorities unnecessarily.—I am, etc.,

E. Molesey, Surrey.

E. M. COLLINS.

### Belladonna Poisoning

SIR,—When it was my privilege—many years ago—to work under the late Dr. Hughlings Jackson at the London Hospital as his house-physician, several cases were contacted in which it was difficult to decide whether the patient was suffering from post-epileptic delirium or belladonna poisoning. Dr. Hughlings Jackson advised that in such cases of doubt a few drops of the patient's urine should be instilled into the eye of a cat, which is extremely sensitive to the drug. This was done; and on several occasions both then and since this procedure, by causing rapid dilatation of the cat's pupil, has proved valuable in determining the diagnosis. This simple help may not be generally known.—I am, etc.,

Manchester.

WILLIAM COATES.

SIR,—I was interested in the case of belladonna poisoning reported by Drs. M. Hamilton and A. B. Sclare (Oct. 18, p. 611) because I am surprised such cases are rare, but chiefly because I suspect the aetiology of the reported case may have been similar to a "near miss" of my own. At all events such cases may serve as a timely warning to Service M.O.s; particularly the more recent entrants.

The incident which prompts me to write this occurred when I had been in the R.A.F. only a month or so. I had under my care an airman with symptoms of peptic ulceration, and ordered for him, in writing, a mixture of magnesium trisilicate (stock) to which should be added 10 min. (0.6 ml.) of tincture of belladonna per dose. The dispensing of this I left in the hands of an orderly. When I came to check the final mixture (which I may have neglected to do) I discovered that liquid extract of belladonna had been added instead of the tincture. Fortunately the patient did not receive any, but two points were brought home to me. First, it is unwise (and, as I later discovered, contrary to Air Force Regulations) to allow inexperienced and unskilled, albeit "kccn," orderlies to carry out even simple dispensing. Personal dispensing will benefit both the patient and the half-forgotten pharmacology of the doctor. Secondly, of the tinctures commonly used in civilian practice many are replaced in the Services, presumably for reasons of economy, by liquid extracts with their lower maximum doses.—I am, etc.,

R. L. G., R.A.F.V.R.

### Genetics and Science in the U.S.S.R.

SIR,—After the self-righteous indignation of the leading article entitled "Ourselves and the Russians" (Aug. 30, p. 339) I was surprised at the crude attack on Soviet science and scientists printed under the title "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616). I do not wish to discuss the scientific pros and cons of the Soviet genetics controversy, but the totally inadequate account given in your article suggests that its author is either extraordinarily ill informed or determined not to do the matter justice. Up to the present one has been inclined to take the more charitable view that your reviewers of Soviet medicine tend to be but poorly briefed. An example is the surprising ignorance of your annotator who thought fit to review work on spinal pumping (July 12, p. 62) though unaware of the existence of an English translation of Speransky's work for no less than twelve years.

In the present case, however, this conclusion is hardly possible. Though no less than five and a half columns were lavished upon the article, a little under one and a half was devoted to an inadequate account of the scientific controversy, and the rest to a vicious attack on Soviet scientific honesty, with a lengthy and slavish reproduction of the totally unfounded allegations of Darlington. It is necessary to state most emphatically that there is not a shred of evidence produced by Darlington or anyone else to suggest either that the death of Vavilov was due to other than natural causes or that he or any other geneticist was at any time under detention. Not only is there no word of truth in these allegations, but those who made them had ample evidence to the contrary before them when they wrote. The monograph of Hudson and Richens to which you pay such tribute contains conclusive proof of the existence and active work of a large Mendelian school in the U.S.S.R. enjoying the full support of the Soviet Government. Furthermore, Zhebrak, the leader of this school, far from being subjected to a "heresy hunt" as you would have us believe, was in May of this year elected president of the Byelo-Russian Academy of Science and is head of the Moscow Agricultural Academy.

One is therefore forced to the conclusion that your article is nothing more than an attempt to blacken Soviet science and is inspired by a determined hostility which readily accepts any scurrilous fable without asking for proof, while at the same time ignoring facts that do not suit your book. In fact the criticisms of Radbil (*Meditsinsky Rabotnik*, July 3, 1947) do not now seem to be so wide of the mark. Nor is it sufficient, in order to protest your innocence, to produce a list of articles by Soviet authors which have appeared in the *B.M.J.* if these were all published during or immediately after the war. In those days the most unexpected people found it necessary to pay lip service to the contribution of a gallant ally, but it is by their subsequent behaviour that the sincerity of these people has been tested. Your own recent attitude has been characterized by a stony silence broken by an ill-informed annotation and two hostile quasi-political editorials. It is a pity that the objectivity and impartiality of Hudson and Richens, to which you pay tribute, cannot also be found in your own attitude. Instead it shows every evidence of the very thing to which you pretend to object—ideological motives obscuring scientific truth.—I am, etc.,

Taunton.

J. R. HAWKINGS.

\* In view of the statements made by Dr. Hawkings we submitted his letter to Dr. Darlington, whose reply follows.—Ed. *B.M.J.*

SIR,—The circumstances of the imprisonment and killing of Vavilov and other leading Russian biologists have been reported this year as follows: Darlington, C. D., *Discovery*, 1947, 8, 40 (February); *Nineteenth Century*, 1947, 142, 157 (September); *J. Heredity*, 1947, 38, 143 (May). Th. Dobzhansky, "N. I. Vavilov, a Martyr of Genetics, 1887-1942," *J. Heredity*, 1947, 38, 227 (August). Eric Ashby, *Manchester Guardian*, Nov. 1, 1947. These reports, disgraceful to the Soviet Government, have never been contradicted officially or unofficially from any Soviet source.

Your correspondent's denial of "scurrilous fables" does not therefore take us any further. We must continue to rely on

that is written in Russia rather than on what is said in Somerset. This difficulty *Pravda*, I think, gives us what we need. On p. 2 the great Moscow journal attempted to answer my "slanders" and to show where genetics, and indeed science in general, stands in Russia. Its attempt was sufficiently convincing to have been quoted and discussed by the *Manchester Guardian* of Sept. 26 in England and the *Dagens Nyheter* of Nov. 4 in Sweden.

In its article entitled "Antipatriotic Acts in the Guise of Scientific Criticism" (for whose translation I am indebted to Prof. Dobzhansky, of Columbia University), *Pravda* rebuked Soviet geneticists Zhebrak and Dubinin for various offences: for believing that there is such a thing as "pure science" and a "single biology" for the world; for having the *petit bourgeois* impertinence to declare that Academician Lysenko was not rewarded by the Supreme Soviet for his success in genetics but only in agriculture; for having defamed their compatriot in "a foreign journal," one "which specializes in maligning Soviet scientists" (to wit, *Science*); and for having lied themselves in so doing with "Darlington, Sax, and their obscurantists from the reactionary capitalist camp" and with "open enemies of the Soviet people" such as Dobzhansky and Timoféeff-Ressovsky.

"A backward part of our Soviet intelligentsia," *Pravda* concludes, "still carries a slavish servility for bourgeois science," whose "rotten roots it is necessary to pull out decisively and pitilessly." Thus there is no denial that Russian geneticists have been put to death; there is merely a threat that the survivors will be pitilessly eradicated.

The *Manchester Guardian*, the *Dagens Nyheter*, Prof. Ashby, and I differ somewhat in our estimates of the seriousness of his threat to the open continuation of honest biological research in Russia. But none of us imagines that the threat is anything less than a matter of life and death for the individuals concerned.—I am, etc.,

John Innes Horticultural Institution.

C. D. DARLINGTON.

SIR.—At first a Victorian reader of your leading article (Oct. 18, p. 616) might feel some doubt whether a non-medical subject bound to stir emotion were suitable for the columns of a medical journal, but reflection suggests that perhaps nowhere else can it be discussed usefully—I mean without pyrotechnic displays of emotions. Doctors, like other men, are swayed by emotion, but have been trained to control its expression. Before we can classify the deaths under discussion, say whether those who died were martyrs in the ordinary sense of the word, we must know whether Communism—by which I mean Russian Communism—is a religion. By religion I mean not the *religio* of Lucretius—viz., fear of the "gods"—but faith in "the eternal not ourselves which makes for righteousness"—Matthew Arnold's definition of God.

In Prof. Arthur Rosenberg's *History of Bolshevism* (O.U.P., 1934, pp. 6-7) we read:

"He (sc. Hegel) believed in an incessant spiritual progress that was always in opposition to itself. Each appearance of the world-spirit (*Weltgeist*) at a definite period in history of necessity gave rise to opposition. It was out of the conflict of power with power that a new and third force was born. This dialectic method when applied by Hegel to his own age clearly taught that the thesis (middle-class society) must be overcome by the antithesis (proletariat) in order to prepare the way for the new synthesis. . . . Only the world-spirit itself is absolute in its eternal progression. In these ideas of Hegel are to be found the chief elements composing Marx's materialistic conception of history."

My first question, directed to those readers who have studied Hegel, is whether Prof. Rosenberg has correctly summarized Hegel's position. The summary seems to imply that Hegel foresaw an infinite succession of conflicts—viz., that the proletarian triumph must yield to another antithesis, the triumph of which would give place to another and so forth. My next question is, do Marxians adopt this philosophy or do they regard the triumph of the proletarian antithesis producing a classless society as definitive, in fact very much as Christians regard the second coming of Christ? If they do, Communism is a religion and a religion implies heretics. If they do not, the question of martyr does not arise, although there may be other questions we could usefully discuss.—I am, etc.,

MAJOR GREENWOOD.

SIR.—Reading the leading article on "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616) I was uncomfortably reminded of the Russian accusation "sham political neutrality of the *B.M.J.*," which was so indignantly denied by you in the *Journal* of Aug. 30 (p. 339). Can it be that the accusation was, after all, correct in essence, if not in detail?

In the autumn number of the *Modern Quarterly* you will find two articles and an editorial footnote devoted to the genetics controversy in the Soviet Union. Two of the writers, geneticists working with the School of Agriculture in Cambridge, while themselves dismissing Lysenko's theory as worthless and regretting the official favour enjoyed by it, make it clear that flourishing schools of orthodox genetics exist and are in fact increasing in importance. And as for the alleged persecution of the Mendelian geneticists, the footnote points out that "Zhebrak, Lysenko's chief opponent, far from being liquidated. . . is very much alive and has just been made President of the Byelo-Russian Academy of Science and is head of the Moscow Agricultural Academy (*Moscow News*, May 17, 1947)."

It seems most regrettable that the *B.M.J.* should lay itself open to a charge of political bias by quoting mischievous rumour from a daily paper without taking the trouble to verify the facts.—I am, etc.,

Birmingham, 15.

C. BACHETIN.

\* The "mischievous rumour" was taken from *Pravda* of Sept. 2, 1947, and has been verified.—Ed., *B.M.J.*

SIR.—The correspondents who have written to you concerning your fair and enlightened leading article, "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616), will find complete answers to their idiotic criticisms in a book *I Chose Freedom* (Hale) just published. It is the political history of a high Russian official, Victor Kravchenko.

You rightly say that "Darlington has done a great service to truth in putting these facts on record." The same applies to Kravchenko about the gruesome facts he also has put on record.—I am, etc.,

T. GERALD GARRY.

SIR.—I was extremely grateful for your courageous leading article on "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616). It is high time that such facts, which have long been available, be made more widely known in face of the pressure to which scientific workers are treated in the way of propagandizing the Soviet Union as the scientist's paradise. The protesting chorus of the faithful may be met, if you will permit me, by invoking a favourite "dialectical" platitude, that art, philosophy, and science are all determined by the form of society in which they are produced, and that, as may be anticipated from this, science is not the only intellectual activity in the U.S.S.R. tyrannized by a mediaeval Inquisition modernized with Gestapo technique.

One may quote the outlawing of psycho-analysis, the imposition of so-called Socialist Realism in art, and the subsequent sudden eclipse of writers and artists who fail to express the "forward march," "aspirations," etc., of "the masses," or who allow "degenerate" bourgeois themes to steal into their symphonies. Recently Shostakovich, the composer, and Eisenstein, the tragic film director—once a leading figure in cinema art—have again performed the nauseating public breast-beating ritual for their "deviations," the new synonym for heresy, and this alone should make your correspondent, who refers to the *B.M.J.* article as "simply another set-piece of anti-Soviet pyrotechnics," squirm; and, if this does not, perhaps the fact that many more artists who are less known perform their confession in the decent privacy provided by the N.K.V.D. will.

One further illustration of the attitude to truth of the Soviet ruling class and its adherents elsewhere is the suppression of the official *History of the Soviet Revolution*. In the Soviet Union itself every available copy was withdrawn and a new version issued in which history was turned on its head, Lenin's "general staff of the revolution" portrayed as counter-revolutionary "mad-dogs," Trotsky, the founder of the Red Army, becoming the arch-saboteur. As far as possible, even the surviving witnesses of historic events were liquidated together with archivists of the Marx-Engels-Lenin Institute in Moscow. In

this country one may still pick up John Reed's stirring account of the revolution, *Ten Days that Shook the World*, which was approved by Lenin, who wrote a foreword to it; yet it is, in the U.S.S.R. and to members of Communist parties elsewhere, a banned book, on the "Index Expurgatorius." The reason is simple: Trotsky is mentioned honourably on every page, Stalin once—as the signatory to a document.

The scientific method, objectivity, and culture as we understand the terms can no more survive in this atmosphere than in Nazi Germany, and they have not flourished so long here that we can afford to be lax in guarding them jealously.—I am, etc.,

Virginia Water Surrey.

HAROLD BOURNE.

\*.\* This correspondence is now closed.—Ed., B.M.J.

### Treatment of Varicose Veins

SIR.—It was with some consternation that I read Dr. R. Simpson Harvey's letter (Nov. 15, p. 793) referring to my method of sclerosing varicose veins by mechanical scarification of the intima (Oct. 25, p. 671) as "barbarous." I have no knowledge of the treatment of varicose veins in barbarian communities, but if he means to infer that the method is cruel to the patient I can reassure him on this point.

The bulk of my cases are done under local analgesia to the incision in the groin (or behind the knee in the case of the external saphena) after usual morphine-scopolamine premedication. About one-third of the patients give no indication that they feel anything; the rest respond with varying degree by movement of the limb operated on, but a little reassurance is all that is necessary to get them to submit with good grace to "seraping" of the vein. The discomfort caused by this method is not to be compared with the painful cramps which follow sclerosing injections with salicylates or sodium chloride.—I am, etc.,

Birmingham.

J. W. RIDDOCH.

### A Word of Praise

SIR.—For thirty-five years, rain or shine, in sickness or in health, for better or for worse, I have not missed reading the *Journal* each week (for a number of years, as you know, it was a duty as well as a pleasure), and I should like to tell you that I have never seen a better number than this week's with the Sherrington symposium. It would perhaps be rash to call it the very best number, but I repeat that I do not remember a better—not primarily because of the excellent articles about Sir Charles Sherrington (I am, alas! but little of a neurologist) but because, in these days when politics overwhelm us all, in and out of the medical profession, it is so refreshing to find in a weekly newspaper the pure light of science held aloft as a beacon for us doctors.

I admire, too, the technical skill with which the *Journal* is reduced, with something in it for everyone (including the dical politicians), from "Synchronous Combined Total trectomy" to "Jugged Hair," the evident authority in the ing articles and the variety in the thirty-three letters to the itor—the life-blood of any weekly journal. In these days of paper restrictions and production difficulties I hope, Sir, that you will allow me to give you and your staff a public word of well-merited praise.—I am, etc.,

London, W 1.

R. SCOTT STEVENSON.

### POINTS FROM LETTERS

#### Bodies for Dissection

Dr. MURIEL KEYES (Harrogate) writes: "D. M. A." (Oct. 11, p. 590) suggests a "Body Donors' Society." Until such be formed it is so simple to bequeath oneself by will to a particular medical school, with the proviso that if distance at time of death make this impracticable then it be offered to the nearest school. An important point is, do the schools prefer us fresh or pickled? Modern embalming by qualified morticians is reasonable in cost and facilitates transport. I believe both Guy's and Liverpool have used bodies so preserved, and I understand that, if so desired, embalming can be followed later by the customary pickling tank. It does not seem generally known how helpful embalming is in ordinary practice. Particularly in cases of unexpected death, relatives who have had to travel from afar have been most grateful to find the face with contour and colouring as they last knew it, and a perfect-looking body with, of course, no suggestion of decomposition.

## Obituary

SIR ALEXANDER MACCORMICK,  
K.C.M.G., M.D., F.R.C.S.

Sir Alexander MacCormick died, on Oct. 25 at his Jersey home, where he had retired after an unusually long career in Sydney in order to be near his children and grandchildren. He was 91, and well known as a surgeon in this country and in Australia.

Alexander MacCormick was born at Tainish, Argyllshire, in 1856. He graduated M.B., C.M. at Edinburgh in 1880, took the M.R.C.S. a year later, and proceeded M.D. in 1885. He had been a house-surgeon at the Liverpool Royal Infirmary and demonstrator in physiology at Edinburgh University before he took up, in 1883, his appointment as demonstrator of anatomy at the University of Sydney, where the late Sir Thomas Anderson Stuart was then demonstrator of physiology. MacCormick was later elected to the surgical staff of the Royal Prince Alfred Hospital and St. Vincent's Hospital, Sydney. He was also consulting surgeon to the St. Vincent Hospital and the Coast Hospital, Little Bay. He was one of the founders of the Royal Australasian College of Surgeons, and he was made an honorary fellow of the Royal College of Surgeons of England in 1900 and of the Edinburgh College in 1905. He was mentioned in dispatches for his services as consulting surgeon with the British Army in the South African War, and he was knighted in 1913. He served in France as a consulting surgeon with the rank of colonel in the 1914-18 war, when he lost his eldest son, Campbell, who was an officer in the Argyll and Sutherland Highlanders. MacCormick had always hoped that Campbell would succeed him at "The Terraces." He was created K.C.M.G. in 1926.

The work of MacCormick and Anderson Stuart was epoch-making in the medical school of the University of Sydney. Anderson Stuart was a great administrator and a great dean of the medical faculty, as well as an able physiologist. MacCormick excelled as an anatomist and as a surgeon, and he was soon appointed lecturer in surgery to the University. Sixty years ago the splitting of surgery into specialties had scarcely begun, and forty years ago, when the older members of the present generation began to know MacCormick well, one would find on his afternoon's operation list at Prince Alfred Hospital a wide range of cases: a cerebral case; a knee-joint; a stomach, gall-bladder, or renal case (for all three); almost always a case of hydatid disease; frequently a carcinoma of the breast, or of the tongue with deposits in the glands of the neck; or a mastoid. One instance of his thoroughness may be given. He had operated upon a patient for epithelioma of the lip, with very extensive glandular involvement. Later there was a recurrence, and the patient stated that he would commit suicide if something more could not be done. MacCormick operated again, but after the metastases had been eradicated the pharynx could not be closed and the skin had to be sutured to the pharyngeal mucous membrane. The patient lived subsequently for twenty years, with his arytenoids and larynx in full view through the pharyngeal window. It was on this patient that Anderson Stuart worked out the mechanism of swallowing. When the patient wanted to swallow a meal he closed the opening by covering it.

Modern methods of confirming diagnosis had not reached their present dependable position at the time when MacCormick started active practice, but his clinical knowledge was unusually sound, his diagnosis shrewd and penetrating. In the operating theatre his practical knowledge of anatomy together with his skill made his approach appear easy. His technique was that of hurry, but his precision was such that operations were

inished cleanly and quickly. It was an especial pleasure to watch his breast operations. Quickly displaying the distal part of the brachial plexus, he cleaned the axillary artery and vein from below upwards, using his own double-ended dissector—one end plain for dissection, the other carrying a ligature. Each tributary vessel was cleaned, ligated, and divided with a technique peculiarly his own; he left a dry dissection behind and advanced on a level front until the axilla was completely cleaned. The extensive dissection of the neck for neglected carcinoma of the tongue, which was all too frequent then, was carried out in the same precise, purposeful manner. In those days private hospitals scarcely existed. Traffic was horse-drawn and big distances had to be covered. MacCormick would perform a fore-quarter amputation, or any other operation, under conditions which were often primitive and with inadequate lighting. Because of this he built his own private hospital, "The Terraces," and thereafter worked in comfort. He appeared to be quite inexhaustible. He arrived at "The Terraces" at 6.30 a.m. and began operating at 7 a.m.; his operations at Prince Alfred Hospital or at the Coast Hospital in the afternoon started at 1.30 p.m. and might go on until after dinner.

He retired from the Prince Alfred Hospital at the age of 65, but he continued to operate for several years more at St. Vincent's Hospital. His mental alertness at the age of 90 is shown by one incident. Knowing that he would enjoy it, the British Council gave a private showing of a recent film. When the pathologist appeared on the screen and made the statement, "It is a squamous-cell carcinoma of the bronchus," quick as thought MacCormick whispered, "How does a squamous-cell carcinoma occur in a bronchus?" He wrote little compared with the vast amount and high quality of his work, but he was responsible for a treatise on the myology of the wild cat and for a number of papers on, for example, cystotomy. Being a canny Scot with unusual business ability, he was in request for the boards of insurance and other companies. He read deeply. His hobby was yachting, and at the age of 73, with two friends of almost the same age and a crew, he sailed his 60-ton yacht from England to Sydney by way of the Panama Canal. His portrait, here reproduced, was painted by John Longstaff and unveiled by H.R.H. the Duke of York in the Great Hall of Sydney University on March 29, 1927. He married in 1895 Miss Ada Cropper, who survives him with his second son and two daughters.

#### CYRIL STRICKLAND, M.D.

Dr. Cyril Strickland, who died at the age of 66 on Nov. 3 in Jersey after a long illness, was born in Port Elizabeth, Cape Colony, in 1881. He was educated at St. Andrew's College, Grahamstown, Oundle School, and Caius College. He graduated at Cambridge with first-class honours in 1902. While he was at St. Bartholomew's Hospital he accepted an invitation to study protozoology at Cambridge under Prof. G. H. F. Nuttall, whose assistant he became. In that capacity he made the interesting discovery that the trypanosomiasis of rats was normally transmitted from rat to rat by the ingestion of infected fleas which were caught and masticated by the animals. Previously it had been assumed that transmission was by the bites of the insects. During this period he found time to take his degree in medicine.

In 1912 he was appointed by the Federated Malay States Government to a post connected with malaria control. Sir Malcolm Watson had already achieved remarkable success in the prevention of malaria by drainage in the low-lying coastal land, but the disease in the jungle upland areas was still a baffling problem. In 1915 Strickland announced the discovery that the hill jungle of Malaya remained free from malaria till clearing operations made the watercourses and pools suitable as breeding-places for the vector mosquitoes. The importance of this discovery was recognized by the Government, which issued an order that jungle must not be cut down close to water collections without an official permit. In India Sir Pardee Lusk, writing in the *Indian Journal of Medical Research*, referred to this work as a "brilliant discovery." Despite this recognition Strickland ever since that time harboured a sense of grievance because of the inadequate acknowledgment accorded to him for so far-reaching an advance in malaria-control methods.

After a short spell of military duty with the New Zealand forces Strickland went to India, where he was employed in work on the prevention of plague till 1922, when he was appointed to the newly established professorship of medical entomology at the Calcutta School of Tropical Medicine and Hygiene. He held this post for seventeen years, and in his own words "during this long period his heart was always in the prevention of malaria by the utilization of his discovery in Malaya, and as far as the tea-gardens of Assam and North Bengal went he had considerable success. A large number of tea-garden doctors took up the story, aided by the great Agency Houses of Calcutta and the estate managers, until the tea-gardens became comparative health resorts, mainly by the use of jungle over the malarifogenic waterways."

In addition to his other fruitful work in teaching and research Strickland made a special study of the association between the formation of deltaic areas and malaria. In 1939 he published a book, *Deltaic Formation*, in which he dealt specially with the deltas of the Ganges and Brahmaputra rivers. He contemplated further work on this subject, especially a correlation of the vast amount of data that he had collected in connexion with the incidence of malaria in Eastern India, but this task was never completed because of his superannuation in 1939. He was then employed by the Army till 1942 in organizing malaria work with special reference to the anticipated Burma campaign.

Dr. GEORGE CLEMENS SCHWIZER was fatally injured in a car accident on Oct. 21. Born in 1903, Schwizer qualified in his native city of Vienna in 1929. After holding several house appointments, one of them under von Eiselsberg, he settled in a small town on the Danube as a general practitioner and surgeon. A Roman Catholic of Jewish descent, he had to leave Austria abruptly in 1938. He came to England and took the conjoint diploma in 1941. After a short spell in general practice he accepted a post as industrial medical officer with the Shell Refinery at Port Ellesmere. There he spared no effort and used all his knowledge and experience in creating a model medical department.—H. G. K.

Dr. DAVID DAVEY ROSEWARNE died suddenly on Nov. 4. A robust New Zealander, he played rugby for St. Mary's Hospital, and after being house-physician there he served in the R.A.M.C. in the 1914-18 war, and then took up practice in East London. His humanity, humour, and hard work, combined with an extensive knowledge of medicine and an intolerance of shams, soon ensured him a large practice. He was one of a rota of doctors who remained permanently on duty throughout the recent war and the blitz, often sleeping in a church crypt. He leaves a widow, his son, Dr. D. D. Rosewarne, and a grandson.—F. S.

## The Services

The President of the U.S.A. has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

*Legion of Merit, Degree of Commander*.—Lieutenant-General Sir Alexander Hood, G.B.E., K.C.B., K.H.P., late R.A.M.C.

*Legion of Merit, Degree of Officer*.—Major-General R. E. Barnsley, C.B., M.C., K.H.S., late R.A.M.C.; Major-General Sir P. S. Tomlinson, K.B.E., C.B., D.S.O., Colonel Commandant, R.A.M.C.; Brigadier (Temporary) E. C. Beddows, O.B.E., M.C., late R.A.M.C.; Colonels (Temporary) E. Bulmer, O.B.E., and A. E. Porritt, C.B.E., and Colonel (local) T. J. L. Thompson, O.B.E., M.C., R.A.M.C.

*Legion of Merit, Degree of Legionnaire*.—Colonel (Temporary) J. P. Douglas, M.B.E., R.A.M.C.

*Bronze Star Medal*.—Major D. H. Thompson, O.B.E., and Captain G. Forrest-Hay, R.A.M.C.

The President of the Czechoslovak Republic has conferred the Medal of Merit 1st Class upon Air Commodores E. D. D. Dickson, C.B.E., and P. C. Livingston, C.B.E., A.F.C., R.A.F., in recognition of valuable services rendered in connexion with the war.

The Efficiency Decoration has been conferred upon the following officers of the Territorial Army: Lieutenant-Colonel (Honorary Colonel) E. N. P. Marland, Lieutenant-Colonel D. A. McMillan, Crawford, O.B.E., Majors (Honorary Lieutenant-Colonels) J. E. Flood, D. M. Mitchell, and G. M. Warrack, D.S.O., O.B.E., Majors W. N. S. Donaldson and M. W. Gonin, D.S.O., and Captain (Honorary Major) D. Arnott, R.A.M.C.

## Medical Notes in Parliament

### Medical Practitioners and Pharmacists Bill

LORD HENDERSON, in the House of Lords on Nov. 11, moved the Second Reading of this Bill, which, he said, was intended to dispose of wartime problems associated with the British medical registration of doctors not possessing British qualifications. It also dealt with pharmacists qualified abroad. The Medical Act of 1886 laid down that admission to the *Medical Register* of doctors holding only diplomas obtained abroad should be conditional upon the existence of reciprocal arrangements. The only foreign countries with which reciprocal arrangements were made were Belgium, Italy, and Japan, and these were cancelled in 1920, 1940, and 1942 respectively. When the war came and doctors from all parts of the world found their way to this country some temporary amendment of the law was called for and was effected in July, 1940, by Defence Regulation 32B, which empowered the General Medical Council to register practitioners qualified to practise outside the United Kingdom. By the time temporary legislation ceased nationals of twenty-six countries had been registered by virtue of foreign diplomas. Independent practice was not permitted, but the help given by these doctors was substantial and a large number served with H.M. Forces or those of allies, while many gave valuable service in hospitals, in the public health services of local authorities, or as assistants in general practice. No further grant of temporary registration was made after February, 1946, but doctors already registered remained so till the end of 1947. The Bill proposed that those who remained in this country and who had given good service in the Forces or in civilian life could obtain permanent registration. When temporary registration ceased there were about 3,500 on the *Register*, including many American and Canadian doctors. Of the others, Germans, Austrians, Poles, and Czechs were the largest classes. It was estimated that not more than 1,500 to 2,000 would avail themselves of the Bill. The figure might be much less, and it would include Polish doctors who had come to this country under the Polish resettlement scheme. The Bill also provided for certain groups who were not registered at all: foreign doctors who had served overseas with British forces and were allowed to enter and remain in the United Kingdom; and doctors who were allowed to enter or remain here during the war but had not been employed in forms of medical work specified in the temporary registration orders. Some had given the country useful service in medical research. This group would include graduates of the Polish school of medicine. It was proposed that for this group registration should in the first place be provisional. During the provisional period they would be required to work in hospitals or other institutions under supervision to enable the General Medical Council to judge their suitability for permanent registration. This provision would be limited to doctors who were in the country when the Bill was introduced. Any question of permanently modifying the general laws which made the registration of foreign doctors dependent on reciprocity would be beyond the intention of the Bill. Clause 8 of Part 1 contained the only provision which would be permanent. Its purpose was to regularize the position of doctors from abroad who visited this country for limited periods to do professional work in hospitals as teachers or as postgraduate students. Many of these visitors were not eligible for registration under the Act of 1886, and it was undesirable that there should be any doubt on the propriety of a registered practitioner co-operating with one of these distinguished visitors. A second group to be covered by this Clause were doctors qualified abroad who came to this country to continue their professional education in temporary appointments at hospitals. The desirable practice of exchanging doctors with the Dominions was in some cases made difficult by the absence of registration. Even if no legal difficulties had arisen in the past the risk had been there and should be removed, especially as hospitals would soon become a State responsibility. Registration would be for the duration of the appointment and only in respect of the appointment, and the Bill gave the General Medical Council the task of assessing the value of medical diplomas held by applicants under the Bill. Part 2 of the Bill changed the law on the registration of pharmacists holding qualifications obtained abroad and also provided for foreign qualified pharmacists.

LORD LLEWELLIN, on behalf of the Conservative Opposition, welcomed the Bill. Lord ALTRINCHAM pointed out that Clause 8, subsection 3, laid down that those who were to be given temporary recognition must hold a colonial or a foreign diploma. If the word colonial was intended to cover the

Dominions it was an improper description and should be altered. Lord HENDERSON promised to look into this and other points, and the Bill was read a second time.

### Committee Stage

The Bill was taken in Committee of the whole House on Nov. 18. On Clause 1 Lord HENDERSON moved to leave out "colonial" and to insert "commonwealth." Since 1886 the *Register* had included separate lists for colonial and foreign practitioners. The unsuitability of the word to present-day conditions was obvious. This amendment and subsequent proposed the use of "commonwealth" and would thus achieve the intention of the Bill without offending the Dominions. The House agreed to the amendment. Meeting a point made previously by Lord Llewellyn, Lord Henderson then moved that the House accept an amendment making subsection 5 of Clause 1 read that direction shall be given only in the case of a person who is resident in the United Kingdom and who is resident therein otherwise than for a temporary purpose.

On Clause 4 Lord Henderson moved an amendment to meet the case of a number of Polish doctors—there were 43 of them—who were not registered and who were still awaiting transfer to this country; they might not arrive by the end of the year. The amendment was accepted. Lord Henderson also accepted an amendment by Lord Llewellyn to extend to "other institutions" the provision for the registration of commonwealth or foreign practitioners temporarily employed in British hospitals. Lord Henderson moved to insert a new clause after Clause 8, substituting "commonwealth" for "colonial" in Part 2 of the Medical Act, 1886. The House agreed to this.

The remaining Clause of the Bill was agreed to and the Committee Stage concluded. The Report Stage was put down for Nov. 25.

### Venereal Disease in the Army

MR. SHINWELL furnished the following table showing the incidence of venereal disease among British troops during the twelve months ended June 30, 1947.

Annual rates per 100 strength

	Officers	Other Ranks	Women's Services
United Kingdom .. .. .	0.4	2.8	1.0 (d)
British Army of the Rhine .. .. .	1.9	16.8	1.2 (d)
Central Mediterranean Force (a) .. .. .	1.8	13.3	
British Troops in Austria (b) .. .. .	1.2	15.2	Not available
Middle East Land Forces (c) .. .. .	0.6	3.0	
Far East Land Forces .. .. .	4.1	13.9	
British Commonwealth Occupation Force (Japan) (d) .. .. .	1.6	30.9	

(a) Includes Austria up to the end of 1946.

(b) Estimated annual rate based on the first 6 months of 1947.

(c) Includes Malta and East Africa from April 1, 1947.

(d) The number of British troops in this Command is small; accordingly the percentage rate is liable to fluctuate considerably.

(e) Officers and other ranks: separate figures for the two categories are not available. As far as is known, however, there were no cases among officers of the Women's Services during this period.

### Cancer Research

MR. HERBERT MORRISON said on Nov. 20 that expenditure on cancer research from the Parliamentary grant-in-aid for the work of the Medical Research Council had been at the rate of approximately £6,000 per annum during the greater part of the last twenty years, this provision being supplementary to the much larger expenditure from the endowments and other resources of unofficial organizations concerned with this particular field. Expenditure from the same source in the financial year 1946-7 was about £12,000, and expenditure in the present financial year was estimated at £31,000 (including £14,000 of a non-recurrent nature). Substantial additional expenditure in the future had been approved for research on the application of atomic physics to the treatment of cancer. These activities were not affected by the National Health Service Act, 1946.

MR. FREEMAN asked if Mr. Morrison knew that deaths from cancer had increased during all this period. He asked whether the Minister was satisfied that the most satisfactory method was applied in allocating the money. Mr. MORRISON said the allocation was the best which could be done. He shared Mr. Freeman's disappointment that the problem had not been solved.

MR. SOMERVILLE HASTINGS asked whether the sum Mr. Morrison had mentioned sufficed for the legitimate demands of the engaged in this research. Mr. MORRISON said he thought that met the needs of the useful activities which could be conducted

Considerable sums were spent elsewhere in the field of research under the Ministry of Health and the hospitals. He would consider further developments in expenditure if useful avenues of research were available.

Lord WINTERTON said that in the opinion of laymen, of hospital authorities, and of the highest members of the medical profession the money in question was being admirably spent. Mr. MORRISON replied that this was his impression.

Dr. MORGAN asked Mr. Morrison to review the evidence on a substance called H 11 which had been used in private research work and to see whether it could be obtained at less cost. Mr. MORRISON said that if he were given particulars he would make inquiries. Sir CHARLES MACANDREW, as a member of the Medical Research Council, said the difficulty was not to secure money, but research experts. He added that the Medical Research Council knew all about H 11. (A leading article on H 11 and papers by H. A. Kidd and by W. E. Gye, R. J. Ludford, and Hilda Barlow appeared in our issue of July 17, 1943.)

**Hospital Contracts.**—Mr. DE LA BERE asked on Nov. 18 whether all contracts made by hospitals would be honoured by the Ministry of Health when the hospitals were taken over. Mr. BEVAN replied that rights and liabilities under contracts made for carrying on the work of a hospital transferable under the National Health Service Act were themselves transferable under Section 6 of the Act.

**Mental Defectives.**—Mr. BEVAN stated on Nov. 20 that premises acquired by local authorities will provide 160 beds for mental defectives in the immediate future. Further accommodation will be available in the new year in three mental deficiency colonies released by Service Departments. Mental defectives awaiting institutional accommodation were 3,890 on Jan. 1, 1947.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

John Henry Dean, M.B., B.Chir., has been appointed University Assistant Pathologist to Addenbrooke's Hospital for three years from Oct. 1.

The degree of M.D. was conferred on E. B. Jarrett and N. D. Compton on Nov. 15.

### UNIVERSITY OF ABERDEEN

In announcing the appointment of Dr. John Craig as the new Professor of Child Health in the University (Nov. 8, p. 753) we wrongly described him as M.R.C.O.G.

Dr. James Walker has been appointed Lecturer in Midwifery and Gynaecology in the University.

### UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examinations indicated:

**PATHOLOGY AND BACTERIOLOGY.**—G. J. Davies, H. E. F. Davies, F. J. Davis, D. M. D. King, J. D. Thomas.

**HYGIENE.**—Maurice M. Bassett, N. V. Chivers, S. I. Cohen, A. V. Coleman, D. P. Davies, G. J. Davies, H. E. F. Davies, F. J. Davis, Joan V. Davis, E. H. Evans, E. F. Griffiths, Anne Guy, E. J. Hargadon, J. M. E. Hyde, E. G. A. Jackson, Marjorie L. James, J. H. Jones, T. D. Jones, D. M. D. King, R. H. Lewis, Joan A. McLay, Lilian M. Morgan, M. A. Owen, E. G. Rees, G. M. Reynolds, Frances M. Richards, J. M. Richards, Sybil H. Stephens, C. E. Stroud, Mary C. Sumption, Augusta J. Taylor, G. Thomas, J. H. S. Wakelin, J. A. Wilkinson.

\* With distinction.

### UNIVERSITY OF LIVERPOOL

Thomas Cecil Gray, M.D., D.A., has been appointed to the newly established whole-time Readership in Anaesthesia in the University. He will organize the teaching of undergraduates and graduates and engage in research.

### UNIVERSITY OF SHEFFIELD

Harry Norman Green, M.D., professor of pathology in the University, has been granted the additional title of Director of Cancer Research.

The Council of the University has received the resignation of John Rennie, M.D., of the post of professor of public health on his retirement from the position of medical officer of health for the City of Sheffield, and has thanked Dr. Rennie for his services to the University.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

Owing to the rise in costs it has been found necessary to increase the charge for the monthly College dinners from £1 1s. to £1 5s (including drinks). The new charge will come into force from Jan. 1, 1948.

At an ordinary meeting of the Council of the College, held on Nov. 13, with Sir Alfred Webb-Johnson, Bt., President, in the chair a Loyal Address in connexion with the impending marriage of H.R.H. The Princess Elizabeth was adopted.

Mr. James M. Wyatt was admitted as a co-opted Member of the Council.

Mr. H. S. Souttar was appointed Hunterian Orator and Mr. L. E. C. Norbury, Bradshaw Lecturer.

The Hallett Prize was awarded to David Henry Cave Harland (St. Bartholomew's).

The following were elected Fellows in Dental Surgery of the College: Sir Frank Colyer, Prof. E. C. Sprawson, Colonel E. B. Dowsett, Mr. Frank Coleman, Mr. T. W. Widdowson, Mr. F. N. Doubleday, Mr. J. H. Badcock, Mr. Wm. Warwick James, Mr. J. G. Turner, Dr. Lilian Lindsay, Mr. A. E. Rowlett, Mr. Bryan J. Wood, Mr. C. S. Morris, Mr. Harold Round, Brigadier R. A. Broderick, and Mr. J. Sim Wallace.

Dr. R. J. Last, Anatomical Curator, was reappointed Bland-Sutton Scholar for a further year; Dr. F. S. Gorrill was appointed Anatomical Curator and Lecturer in Anatomy; and Dr. B. Schofield was appointed Lecturer in Physiology.

Leverulme Scholarships were awarded to Mr. E. S. R. Hughes for research into spontaneous thrombosis of the axillary vein and to Mr. H. Daintree Johnson for research into gastric physiology in relation to surgery and cardiovascular surgery, particularly in relation to portal hypertension.

The following hospitals were recognized in respect of the resident surgical posts required of candidates for the Final Fellowship examination: Chase Farm Hospital (two assistant surgeons, four senior house-surgeons, and one casualty officer); City General Hospital, Leicester (resident surgical officer and two house-surgeons); Luton and Dunstable Hospital (casualty house-surgeon and orthopaedic house-surgeon); Churchill Hospital, Headington (one house-surgeon (B2)); Scunthorpe and District Hospital (resident surgical officer and orthopaedic house-surgeon).

### Diplomas

Diplomas of Membership were granted to D. J. Parr and J. C. E. Pougher and to the 129 successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Nov. 15 (p. 800); as were the names of the successful candidates for the Diplomas in Child Health and in Medical Radio-Diagnosis.

Diplomas in Medical Radiotherapy were granted to D. K. Sambrook and to the other successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Nov. 15 (p. 800).

Diplomas in Physical Medicine were granted, jointly with the Royal College of Physicians of London, to W. R. Grant and A. K. Tyler, and a Diploma in Ophthalmic Medicine and Surgery, also jointly, to E. Hefferman.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Dr. William Evans, F.R.C.P., will deliver the Finlayson Memorial Lecture in the Hall of the Faculty (242, St. Vincent Street, Glasgow) on Wednesday, Dec. 3, at 5 p.m. The title of the lecture is "Heart Murmurs." All medical practitioners are invited to attend.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At a meeting of the President and Fellows of the College on Nov. 7 the following were admitted to the Membership: T. J. Ryan, J. W. Wagner, M. Millard, G. A. C. Miller.

### CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been granted the diploma of L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.S.Glasg.: A. Alakija, J. M. Brownlie, L. Charles, W. J. C. Colin-Thome, R. S. Cowie, A. M. Darwish, T. P. Edwards, P. H. T. Fok, S. Gordon, J. A. Gray, W. S. Hall, M. Harris, Patricia E. Hartley, J. M. Hillock, E. Katz, D. P. Keith, S. Lipson, M. Lloyd-Jones, P. Macpherson, Hilary E. C. Millar, H. G. C. Payne, A. I. Richardson, J. R. Scott, Joan C. R. Shiell, H. Simmons, H. S. Sloane, J. D. Stewart.

# INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever ..	39	3	23	2	—	46	4	25	2	3

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.  
† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.  
‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

Neonatal Gastro-enteritis at Scunthorpe  
There have been five deaths recently among babies in the children's ward at the Scunthorpe War Memorial Hospital. The details are as follows:

1. A male aged 6 months had previously been under treatment for a cleft lip. He was admitted on Oct. 25 as a possible case of tuberculous meningitis. He died two days later after vomiting several times and a moderate degree of enteritis. Post-mortem examination showed evidence of enteritis.
2. A girl aged 4 months had been under investigation from Oct. 26 to 28 and had been readmitted on Oct. 30 with a strangulated hernia, which was operated on. She started with diarrhoea and vomiting on Oct. 31 and died on Nov. 14.
3. A male aged 8 weeks was admitted on Oct. 8 with pyloric stenosis. He developed diarrhoea and vomiting on Nov. 3 and died on Nov. 10.
4. A male aged 6 weeks was admitted on Nov. 2 with pyloric stenosis. Diarrhoea and vomiting appeared on Nov. 8 and the boy died on Nov. 12.
5. A male aged 14 months had been admitted on June 18 with coeliac disease. Diarrhoea and vomiting were noted on Nov. 8 and he died on Nov. 17.

Other babies were infected, and in two of them diarrhoea and vomiting appeared on Oct. 31. The others developed the same symptoms on Nov. 1, 3, 4, and 17. One was a convalescent poliomyelitis case, two were admitted with meningitis, one had bronchopneumonia, and two were orthopaedic cases. No organisms were isolated from the faeces of any of the cases or from samples taken from the remaining 17 children in the hospital ward. None of these babies were breast fed. All were bottle fed on National dried milk, and all bottles and teats were pooled for boiling after each feed.

### Poliomyelitis

The fall in the notifications of poliomyelitis 186 (198) was again a small one, and there was a small rise in those of poliomyelitis 15 (12) in the week ending Nov. 15. Figures for the previous week are shown in parentheses. Notifications of poliomyelitis in London A.C. were 12 (16), and most of the southern counties showed small reductions except Kent 15 (4) and East Sussex 9 (3). The northern counties also showed reductions for the most part, but there was a tendency to small increases in East Anglia and the West.

### Discussion of Table

In England and Wales an increase was recorded in the notifications of scarlet fever 201, measles 127, diphtheria 41, and whooping-cough 35. Decreases were reported in the incidence of acute poliomyelitis 23 and dysentery 21.

A small rise in the incidence of scarlet fever was recorded in most areas of the country; the largest rise was that of Yorkshire West Riding 31. The largest increases in the notifications of measles were those of Lancashire 54, Monmouthshire 41, Glamorganshire 35, and Derbyshire 33; the largest decreases in Yorkshire West Riding 62.

The only notable variation in the returns for diphtheria was an increase of 19 in Lancashire; the notifications in Liverpool C.B. rose from 21 to 32. A further 53 cases of dysentery were notified from the outbreak in Berkshire, Wallingford R.D.; 368 cases have been notified in this area during the past three weeks (see Nov. 22, p. 850).

The largest returns of poliomyelitis were Lancashire 34, Middlesex 19, and London 16. Two outbreaks of gastro-enteritis in maternity hospitals have been reported. The outbreak in Cardiff caused the deaths of 8 babies aged under one month, and the outbreak in Lincolnshire resulted in 5 deaths.

In Scotland there were increases in the notifications of acute primary pneumonia 90, measles 60, and scarlet fever 10. The only falls in incidence were diphtheria 8, and acute poliomyelitis 7. The increased incidence was mainly confined to the city of Glasgow, where there were rises in the notification of acute primary pneumonia 79, and measles 54. In Eire a rise was reported in the incidence of diarrhoea and enteritis 15 and whooping-cough 15. Cases of diphtheria, scarlet fever 16 and whooping-cough 15. Cases of diphtheria were reported from 14 administrative areas, compared with areas last week.

# Vitamin Therapy—its uses and limitations

## GROWTH REQUIREMENTS IN CHILDHOOD

The relatively high metabolic needs of growing children must be met not only by energy-producing foods, but also by the factors needed for their metabolism, namely vitamin B<sub>1</sub> (aneurine) and the co-enzymes of the vitamin B<sub>2</sub> complex. Failure to supply these may be revealed in poor growth, debility, abnormal fatigue. Such a combination is highly suggestive of a deficiency of the factors—vitamins, protein, minerals—so richly supplied by Bemax.

### BEMAX

*Stabilised cereal embryo*

1 oz. of Bemax provides approximately:—

Vitamin B <sub>1</sub>	0.45 mg.	Vitamin E	8.0 mg.	Protein	30%
Vitamin B <sub>2</sub>	0.3 mg.	Manganese	4.0 mg.	Available Carbo-	
(Riboflavin)		Iron	2.7 mg.	hydrate	39%
Nicotinic Acid	1.7 mg.	Copper	0.45 mg.	Fibre	2%
Vitamin B <sub>6</sub>	0.45 mg.			Calorific Value	104

References: Shortage of space precludes list of references but full documentation may be obtained on application to Clinical Research Dept. 27A.

### BEMAX TABLETS

Six tablets provide the same amount of vitamin B<sub>1</sub> as the daily dose of Bemax. The tablets contain 50% Bemax, are tasty and should be chewed.

*Vitamins Limited*

TRADE MARK

## 'ANTHISAN'

BRAND

pyranisamine maleate

a recent advance in the treatment of allergic conditions

LIMITED SUPPLIES OF 'ANTHISAN' ARE NOW AVAILABLE  
'ANTHISAN' is a substance with a powerful antihistaminic activity and of low toxicity.

Following encouraging reports on its use in the treatment of serum sickness, angio-neurotic oedema, hay fever, vasomotor rhinitis and allergic skin conditions it is now made available. In limited quantities, to the medical profession, through the usual trade channels.

SUPPLIES: TABLETS  
containers of 25 x 0.10 gramme.  
500 x 0.10 gramme.  
AMPOULES  
boxes of 10 x 2 c.c. 50 x 2 c.c.

Further Information is available from our Medical Information Department (phone ILford 3050, exts. 99 and 100)

### COLLUMINA

Regd. Trade Mark

aluminium hydroxide preparations  
for effective antacid treatment

A highly active, acid-soluble aluminium hydroxide (otherwise known as hydrous oxide of aluminium) is the basis of all Collumina preparations.

#### POWDER

A new preparation available as an alternative to the suspension. Collumina Powder corresponds to the Dried Aluminium Hydroxide Gel (U.S.P. XIII). 1 gram. will neutralize 250 ml of N/10 HCl in one hour.

Bottles of 50 grm.

#### TABLETS

A new preparation. Each tablet contains 5 grains of aluminium hydroxide powder with suitable flavouring.

Bottles of 60 tablets.

#### SUSPENSION

The original preparation known as Collumina and containing 5% to 6% of aluminium hydroxide in aqueous suspension, with suitable flavouring. 5 c.c. will neutralize 100 c.c. of N/10 HCl in 10 to 15 minutes.

Bottles of 8 fl. oz. and 40 fl. oz.

A new brochure on aluminium hydroxide therapy is available on request.

## 'TRILENE' ANALGESIA IN OBSTETRICS

'Trilene' produces an effective and constant plane of analgesia which can be easily maintained without loss of consciousness.

In midwifery its auto-administration by means of various types of inhaler has proved highly satisfactory for relieving labour pains; the analgesia produced is adequate and safe for mother and child.

There are no contra-indications, untoward effects are rare and recovery is rapid. The method is simple and convenient and secures the ready co-operation of the patient.

'Trilene' is issued in containers of  
8 oz. and 1 lb.

## FARADISM-FREE cutting current

The cutting current of the Universal Diathermy is valve-generated—no spark gaps to adjust, no points to clean. Output is smooth, consistent, and entirely free from spurious faradic impulses. The surgeon will appreciate these advantages in an exceptionally wide range of operative procedures, since the Universal Diathermy has been specially designed for all-purpose hospital use. Additional facilities include diagnostic accessories, electric cautery, and built-in centrifugal suction unit. Full description of this Marconi valve-operated instrument on request.

75, New Cavendish St., London, W.1

## WEATHERING THE FORTIES

The Roaring Forties were a searching test of seaworthiness for the sailing ship. So for men are the Forties—in years of age—a period of stress, revealing any latent defect. It is then that many observe the first symptoms of hypertension.

If business commitments allow no easing of physical and mental strain, symptomatic treatment is indicated. This improves the patient's psychological state and tends to check progress of the condition.

'Theominal' is a preparation combining vasodilator, sedative and antispasmodic properties. Its wide use in hypertension attests its value.

## 'THEOMINAL' IN HYPERTENSION

*'Theominal' is a combination  
of 'Luminal' and 'Theobromine'*

*Packings of 20, 50, 250 tablets*

**BAYER PRODUCTS LTD - AFRICA HOUSE - LONDON W.C.2**

In Northern Ireland an increase of 15 in the notifications of scarlet fever resulted in the largest return for this disease in recent months. Of the 63 cases of scarlet fever 32 were notified in Belfast C.B.

### Week Ending November 15

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,947, whooping-cough 1,217, diphtheria 195, measles 2,355, acute pneumonia 582, cerebrospinal fever 40, acute poliomyelitis 186, acute poliomyelitis 15, dysentery 95, paratyphoid 8, and typhoid 11.

## Medical News

### Hearing-aids and Audiometers

The Committee on Electro-acoustics, which was appointed by the Medical Research Council in February, 1944, has now issued its Report on Hearing Aids and Audiometers (Med. Res. Cncl. Spec. Rep. Ser. No. 261). This committee is one of three that were appointed by the Medical Research Council in 1944 in response to a request by the Ministry of Health for advice on how to deal with the problem of deafness in the nation; the other two committees were those on Medical and Surgical Problems of Deafness, and on the Education of the Deaf. The members of the Committee on Electro-acoustics are as follows: Mr. W. G. Radley, Ph.D. (Chairman); Sir W. Lawrence Bragg, F.R.S.; Mr. R. S. Dadson, M.A.; Dr. C. S. Hallpike; Col. D. McMillan; Mr. L. C. Pocock, M.Sc.; and Mr. T. S. Littler, M.Sc. (Secretary). The committee undertook two principal tasks: (1) to determine the practicability of designing a single type of electrically operated hearing-aid which would be small, light, reasonably cheap, and be suitable for most persons with deafness of types that can be benefited by mechanical appliances; (2) to determine satisfactory performance specifications for pure-tone audiometers for use in the early diagnosis and accurate assessment of different types of deafness. Details of the committee's investigations are contained in this Report. The Ministry of Health has already arranged for the large-scale manufacture of a hearing-aid on the lines recommended in this Report, and it is hoped that it will be possible to start distributing the aids by the time the National Health Service Act, 1946, comes into operation. The Ministry of Health states that in due course a public announcement will be made about the clinical testing of deaf people and supplying the Government hearing-aid. It is proposed that they should be issued to deaf patients on the recommendation of ear specialists at a number of hospital clinics throughout the country, and plans are being made for providing the clinics with the technical services required for the efficient dispensing and maintenance of the aids. The Ministry hope also to provide at these clinics a standard type of pure-tone audiometer which will satisfy the committee's requirements.

### The Gordon Hospital

The Duchess of Kent will formally reopen the Gordon Hospital (Vauxhall Bridge Road, London, S.W.) on Tuesday, Dec. 2, at 3 p.m. During the war the hospital was used as a Services club.

### New Member of Spens Committees

The Minister of Health and Secretary of State for Scotland have appointed Sir Horace P. Hamilton to be a member of the inter-departmental committees under the chairmanship of Sir Will Spens which are considering (a) what ought to be the range of total professional income of a registered dental practitioner in any publicly organized service of general dental practice, and (b) what ought to be the range of remuneration in the different branches of consultant and specialist practice in any publicly organized hospital and specialist service. He succeeds Sir Thomas Gardiner, who has been appointed Chairman of the New Town Development Corporation for Stevenage. Sir Horace Hamilton was the Permanent Under-Secretary of State for Scotland from 1937 to 1946.

### Chelsea Clinical Society

The second dinner meeting of the new session was held on Nov. 11 with the President, Dr. Neil MacLay, in the chair. Mr. Geoffrey Parker described his experiences as surgeon to the Maquis.

### Anaesthetists in the South-west

A Society of Anaesthetists of the South-west Region has been formed. The inaugural meeting was held at Bristol on Nov. 14 and 15, when Dr. Bradbeer, of Bristol, was elected President for the coming year. Prof. R. R. Macintosh lectured on "Anaesthesia used for Research Purposes."

### Anaesthetist Visits Italy

Dr. G. Organe, consultant anaesthetist to Westminster Hospital, has gone for a three weeks' lecture tour in Italy to introduce the latest methods of anaesthesia to the Italian medical profession. Dr. Organe will lecture in Italian and will give demonstrations in Rome, Naples, Bologna, and Milan.

### British Council Scholarships

The British Council has awarded 256 scholarships to graduates from 62 countries, including the Dominions and Colonies, and extended the scholarships of 106 other scholars. Forty-four of these scholarships are in medical subjects, and the scholars will train at many of the leading hospitals in the country, including the Royal Derbyshire Infirmary; the Royal Infirmary, Glasgow; the Plastic Surgery Unit, Oxford; the Children's Hospital, Birmingham; the Royal Cancer Hospital, London; the Manchester Royal Infirmary; and the Children's Hospital, Great Ormond Street, London.

### General Smuts

General Smuts, the Prime Minister of South Africa, was admitted to Honorary Fellowship of the Royal College of Obstetricians and Gynaecologists on Nov. 22.

### Sir Godfrey Huggins

Sir Godfrey Martin Huggins, F.R.C.S., who has been Premier of Southern Rhodesia since 1934, has been appointed to the Privy Council.

### Atomic Energy Commission

The United States Atomic Energy Commission has appointed Dr. Shields Warren, Director of the Massachusetts State Tumor Diagnosis Unit, interim director of its newly established Division of Biology and Medicine. The Division will correlate research in the A.E.C. and private laboratories.

### City of Plymouth Mental Hospital

The City of Plymouth Mental Hospital, previously known to Plymouthians as Blackadon, has been renamed Moorhaven Hospital. The early treatment unit will continue to be known as Moorfields Hospital. The postal address in each case is Ivybridge, S. Devon.

### New Birth Certificates

A new form of birth certificate will be brought into use on Dec. 15. It will not show particulars of parentage or adoption, but only the name and surname, sex, date of birth, and place of birth.

### Penicillin Factory

The penicillin factory at Speke, Liverpool, which has been operated for the Ministry of Supply by the Distillers Company Ltd. since Dec., 1945, will become a commercial undertaking on Dec. 1 of this year. A new company has been formed for the purpose; it will be called the Distillers Company (Biochemicals) Ltd.

### Wills

Dr. Robert George Clements, of Southport, left £18,047. Dr. Lancelot Raoul Lempriere, of Ware, Herts, left £32,456. Mr. William Ernest Miles, formerly consulting surgeon to the Royal Cancer Hospital, left £14,856. Dr. Walter Ramsden, Johnston Professor of Biochemistry at Liverpool University, 1914-31, and formerly lecturer in chemical physiology at Oxford, left £23,169.

## COMING EVENTS

### Ethics and Science

A conference will take place on Dec. 4, beginning at 10.30 a.m., in the Livingstone Hall, Tothill Street, Westminster, S.W.1. Its main theme will be "Society and the Individual," which will be considered under two aspects—namely, "The Value Society Sets Upon the Individual," and "The Values the Individual Sets Before Himself." There will be discussions after both the morning and afternoon sessions and at an open meeting in the evening. The aim of the conference is to effect in some measure a synthesis between the spiritual and the scientific interpretations of life. The chair will be taken by Prof. Winifred Cullis and Dr. E. B. Sirauss. Further information and tickets (members of Council 2s. 6d., others 3s. 6d.) may be obtained from the British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1 (Tel. Euston 4732).

### Faculty of Homoeopathy

A meeting of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital, Great Ormond Street, W.C., on Thursday, Dec. 4, at 5 p.m., when Mr. Harold Dodd will give an address on "Five Ailments Aggravated by Present Austerity Conditions."

**Metallie Contaminants in Foodstuffs**

A joint meeting of the Food Group of the Society of Chemical Industry and the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's Rooms (Burlington House, Piccadilly, London, W.) on Wednesday, Dec. 3, at 7 p.m., when papers on "The Occurrence, Physiological Importance and Estimation of Metallic Contaminants in Foodstuffs" will be presented by Messrs. G. E. Forstner, G. W. Monier-Williams, W. F. J. Cuthbertson, and N. L. Allport and D. E. Garratt. A discussion will follow.

**Medical Society of the L.C.C. Service**

A clinical meeting of the Medical Society of the L.C.C. Service will be held at Lewisham Hospital on Thursday, Dec. 4, at 3 p.m.

**Heberden Society**

A clinical meeting of the Heberden Society will be held at West London Hospital, Hammersmith, W., on Friday, Dec. 5, at 5 p.m.

**Housing and Health**

Dr. J. H. F. Brotherton will lecture on "Housing and Health" on Dec. 16 at the Housing Centre, 13, Suffolk Street, Haymarket, London, S.W.1 (Tel. Whitehall 2881).

**SOCIETIES AND LECTURES****ROYAL SOCIETY OF MEDICINE**

*Section of Orthopaedics.*—Tuesday, Dec. 2, 5.30 p.m. (Cases at 4.30 p.m.) Cases will be shown.

*Section of History of Medicine.*—Wednesday, Dec. 3, 2.30 p.m. Papers by Dr. E. Ashworth Underwood; Charles Creighton (1847-1927): Scholar, Historian, and Epidemiologist; Prof. Major Greenwood: Certain Aspects of the Epidemiology of Creighton.

*Section of Epidemiology and State Medicine.*—Members of this Section are specially invited to attend.

*Section of Surgery.*—Wednesday, Dec. 3, 8 p.m. Discussion: The Treatment of Carcinoma of the Breast. Openers: Sir Gordon Gordon-Taylor, Mr. R. McWhirter, and Sir Stanford Cade.

*Section of Radiology.*—Members of this Section are specially invited to attend.

*Section of Neurology.*—Thursday, Dec. 4, 8 p.m. Discussion: Electro-encephalogram in Organic Cerebral Disease. Opener: Dr. W. Grey Walter. Followed by: Drs. Denis Hill and Denis Williams.

*Section of Otolaryngology.*—Friday, Dec. 5, 10.30 a.m. Papers by Mr. I. Simson Hall and Dr. A. Young: Penicillin Treatment in Acute Suppurative Otitis Media with Special Reference to Long-term Hearing.

*Section of Laryngology.*—Friday, Dec. 5, 2.30 p.m. Films: Mr. G. H. Bateman: Organic Disorders of the Larynx; Mr. V. E. Negus: Bell Telephone Film of Larynx.

*Section of Anaesthetics.*—Friday, Dec. 5, 5.30 p.m. Paper by Dr. J. K. Hasler: Posture in Anaesthesia.

**CHADWICK TRUST.**—At St. Mary's Hospital Medical School, Norfolk Place, Praed Street, W., Thursday, December 4, 4.30 p.m. Dr. G. B. Mitchell-Heggs: Some Changes in Dermatology since the time of Sir Malcolm Morris.

**DON UNIVERSITY.**—At Goldsmiths' College, Lewisham Way, New Cross, S.E. Monday, Dec. 1, 7.30 p.m. Speech-demonstration: Stammering. Orator. Short addresses by members of Speech Disability Classes.

**ROYAL MEDICAL SOCIETY.** 7, Melbourne Place, Edinburgh.—Friday, Dec. 5, 8 p.m. Dissertation by Mr. M. D. W. Low: Uræmia and Some Methods of Treatment.

**POSTGRADUATE DIARY**

**EDINBURGH UNIVERSITY.**—Monday, May 3, 1948, 9 a.m., 12th General Fortnight Refresher Course begins. Intended primarily for demobilized medical officers (Class II) and for insurance practitioners. Fee for graduates not claiming expenses from Government sources, 10 gns.

**INSTITUTE OF DERMATOLOGY.** 5, Lisle Street, Leicester Square, London, W.C.—Tuesday, Dec. 2, 5 p.m. Dr. R. M. B. MacKenna: The Erythema Group of Eruptions. Thursday, Dec. 4, 5 p.m. Dr. R. T. Brain: Filtrable Viruses.

**LONDON CHEST HOSPITAL.** Victoria Park, E.—Friday, Dec. 5, 5 p.m. Dr. S. Roodhouse-Glyne: Pneumoconiosis.

A clinico-pathological demonstration will be held in the Meyerstein Lecture Theatre of the Westminster Hospital School of Medicine, Horseferry Road, London, S.W.1, on Monday, Dec. 1, at 5 p.m. The condition to be demonstrated is osteogenic sarcoma.

**APPOINTMENTS**

Dr. R. F. MacKenzie has been appointed medical officer of the North-eastern and Scottish Areas of the L.N.E.R. in succession to Dr. J. D. Gunn, who has retired.

Dr. MacKenzie qualified at Glasgow University in 1937; in 1944 he was appointed medical officer of the Silicosis Board at Cardiff, and remained there until May, 1946.

Mr. R. J. Fenney, B.A., previously Assistant Secretary, has been appointed Secretary and Chief Executive Officer of the Central Midwives Board in succession to Mr. A. J. Bennett, M.A., who has been appointed Secretary to the North-west Metropolitan Regional Hospital Board.

Dr. Luiz Araujo has been appointed President of the Medical Surgical Society of Pará, Brazil.

Lieut.-Col. C. Newton-Davis, M.C., J.P., I.M.S. (ret.), has been appointed chairman of the Health Committee of the Hampshire County Council.

Major G. M. Thomson, M.D., M.R.C.P.Ed., D.P.H., has been appointed Adviser on Venereal Diseases Control to the West Indian Governments.

Major-Gen. E. A. Sutton, C.B., C.B.E., M.C., K.H.S., succeeds Lieut.-Col. A. D. Stewart as Superintendent of the Royal Infirmary Edinburgh.

Previous appointments that Major-Gen. Sutton has held include that of D.D.M.S. Western Desert Force under Lord Wavell, D.M.S. East Africa Command, and Chief (British) Medical Adviser, S.H.A.E.F.

BROWNE, O'DONELL, T. D., M.B., B.Ch., F.R.C.P.I., F.R.C.O.G., Professor of Midwifery, Trinity College, Dublin, has been appointed Master of the Rotunda Hospital, Dublin, in succession to Dr. Ninian McL. Falkner, F.R.C.P.I., F.R.C.O.G., who completed his seven years' term as Master on Nov. 7.

MCNAB, G. R., M.D., F.R.C.P.Ed., Assistant Physician, Berks and Bucks Joint Sanatorium, Peppard Common, Henley-on-Thames, Oxon.

SUTTON, EVELYN ALEXANDER, C.B., C.B.E., M.C., M.R.C.S., L.R.C.P., Major-General, late R.A.M.C., Honorary Surgeon to the King, has been appointed Superintendent of the Edinburgh Royal Infirmary.

THOMPSON, W., F.R.C.S., Chief Assistant to a Surgical Unit, Manchester Royal Infirmary.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

Hartley.—On Nov. 6, 1947, at Radmoor Nursing Home, Loughborough, to Wendy (Joyce Bell) and Peter L. M. Hartley, M.B., B.Ch., a son—Peter Rupert.

Lister.—On Nov. 13, 1947, at Parkgrove, Glasgow, to Nancy B. Thomson, M.A., wife of Dr. James A. Lister, 549, Alexandra Parade, Glasgow, a son—Alas Andrew.

MacAuliffe.—On Oct. 30, 1947, at Purey Cust Nursing Home, York, to Lady (née Baldry), wife of Dr. Richard MacAuliffe, a daughter—Jane Mary.

Podoloff.—On Nov. 8, 1947, at South London Hospital for Women, to Diana (née Myott), M.B., B.S., wife of Paul Podoloff, a son.

**MARRIAGE**

Whowell—Murray.—On Nov. 15, 1947, in London, W. Brian Whowell, M.B., B.S., to Joy Murray, M.S.R.

**DEATHS**

Atkinson-Fleming.—On Nov. 14, 1947, in London, Frederick Charles Atkinson-Fleming, M.C., M.B., B.Ch., Major R.A.M.C., retired.

Bentall.—On Nov. 16, 1947, William Charles Bentall, O.B.E., F.R.C.S.Ed., Knight of the Order of St. John of Jerusalem.

Bourman.—On Nov. 8, 1947, at Amsterdam, Prof. K. H. Bourman, M.D., aged 73.

Cosgrove.—On Nov. 17, 1947, at Sydney, Australia, Charles Cosgrove, M.C., F.R.C.P.S.Ed.

Eaves.—On Nov. 21, 1947, Elizabeth Cowper Eaves, M.D., D.P.M., at 2, The Mount, Sheffield.

Farquharson.—On Nov. 16, 1947, at All Saints' Hospital, Southsea, SE, George Sinclair Farquharson, M.B.

Herring.—On Nov. 22, 1947, at 50, Harley Street, London, W., Herbert Thomas Herring, O.B.E., M.B., B.S.

Hunt.—On Nov. 22, 1947, in London, David Mackenzie Hunt, L.M.S.S.A.

Knight.—On Nov. 18, 1947, at Falkland House, Painswick, Charles Victor Knight, M.D., aged 75.

Lapcumb.—On Nov. 19, 1947, at Kewick, Thomas Walter Lapcumb, M.B., M.Ch., F.R.A.C.S., of Sydney, Australia.

Macintosh.—On Nov. 21, 1947, at Edinburgh, Ebenezer Crombie Macintosh, F.R.C.P.S.Ed.

McRae.—On Nov. 20, 1947, at 63, Organs Road, Edinburgh, Douglas Alexander Clouston McRae, M.B., Ch.B., aged 32.

Mannew.—On Nov. 6, 1947, at Sandway Lodge, Prestatyn, Henry John Mannew, M.D., aged 82.

Montgomery.—On Nov. 19, 1947, at 3, High Street, Walsington, Staffs, Pauline Montgomery, M.D.

O'Donnell.—Sir Thomas Joseph O'Donnell, K.C.I.E., C.B., D.S.O., F.R.C.P.I., Major-General A.M.S., retired.

Rosewarne.—On Nov. 4, 1947, David Davey Rosewarne, M.R.C.S.

Sharpe.—On Nov. 17, 1947, Harry Arthur Sharpe, M.R.C.S.

Wood.—On Nov. 23, 1947, at City Hospital, Edinburgh, Robert Cameron Wood, M.B., Ch.B.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### B.C.G. Vaccination

**Q.**—Is it advisable to vaccinate a healthy child of three months with B.C.G.? He lives with his father, who has open pulmonary tuberculosis. It is an only child and the mother is healthy. At what age is B.C.G. used and how many injections are necessary? Are there any dangers?

**A.**—B.C.G. is not yet obtainable in this country, but the Ministry of Health is understood to be taking steps to make it available. Its use will then presumably be entrusted to tuberculosis officers and others with special experience, who will undertake to administer it according to some prearranged plan and for certain definite indications. Opinion on the value of B.C.G. vaccination is not unanimous, and it seems desirable that its use in this country should be controlled until more evidence has been obtained. The infant with a sputum-positive parent has always been considered a candidate for this treatment; vaccination has usually been carried out shortly after birth and the child removed from the household for several months afterwards in order that it may have time to develop immunity before exposure to infection. (See also the opening article in this week's issue and our leading article at p. 873.)

### Effects and Legality of Sterilization

**Q.**—(a) Does vasectomy have any effect, other than producing sterility, on male functions generally—libido and coitus in particular? (b) Is sterilization of males or females illegal? If so, does this apply also to sterilization for therapeutic reasons?

**A.**—(a) It is rare for a sterilizing operation such as vasectomy to have any effect on libido or coitus. The writer can recall only one patient who complained of a diminution in the volume of the ejaculate after he had undergone division of the vasa, but even he did not consider that this brought about a lowering of satisfaction. Theoretically (on the basis of Ancel's and Bouin's experiments on animals) ligation should bring about an increase in sexual desire, but in practice in human beings this has not been found to be the case.

(a) There is no statute which prohibits sterilization. Such a procedure may be an example of the common-law crime of "mayhem," or maiming, but no prosecution has been instituted for this offence in recent times, and it is generally regarded now as obsolete. Sterilization, like any other surgical procedure, may amount to an assault unless carried out with the patient's consent; or, if the patient is under legal disability (for example, is a minor or of unsound mind), the consent must be obtained from the person who has authority to give it on his behalf. No action for assault will lie if such consent has been obtained and if there are reasonable grounds for the treatment, such as to save life or to cure disease. For example, it would be quite reasonable to sterilize a woman suffering from rheumatic carditis to such a degree as to make pregnancy dangerous to life. It is quite proper to ligate the spermatic cords in a male during the operation of prostatectomy in order to reduce the risk of epididymitis. Special precautions are advisable when the patient is married, and it is best to obtain the consent not only of the patient but also of the partner, after a full explanation of the circumstances of the case. One of the medical protection societies has suggested standard forms of consent worded as follows:

1. For a woman: "I, ..... of ..... hereby consent to undergo the operation of ..... the effect and nature of which have been explained to me."

2. For a husband: "I, ..... of ..... the husband of the above-named ..... hereby also consent to such operation."

3. For either sex: "I, ..... of ..... hereby consent to undergo the operation of ..... and/or such further or alternative operative measures as may be found to be necessary during the course of such operation."

(The latter part of the third formula could be deleted if not required.)

In view of the serious and irrevocable consequences which follow a sterilization operation, it is often advisable, as in the case of a contemplated operation to terminate pregnancy, to obtain the opinion of an independent medical colleague before carrying out the operation. Sterilization is sometimes advocated on eugenic grounds—for instance, to prevent the transmission of hereditary disease; it is probably illegal to perform such an operation, but the point has not so far been tested in the courts.

### Prophylaxis of Dental Caries

**Q.**—Is there any effective preventive treatment for recurrent exacerbations of dental caries in young adolescents? In view of the amount of calcium in the present flour, and of calciferol in butter and margarine, should additional doses of these essential dentine-forming substances be given? Is massive dosage with vitamin D to be recommended? Among other aetiological factors a deficiency of fluorine has been mentioned. Another possible factor in causation of dental caries in adolescents may be traceable to overdosage with vitamin D during the early 1930's, when the enthusiasm of manufacturers tended to outrun discretion, with the result that children were given daily doses greatly in excess of 2,000 i.u.

**A.**—Our knowledge of the precise aetiology of dental caries is unfortunately still so incomplete that no single prophylactic measure can be advised that will certainly lessen the incidence in adolescents. Recently doubt has been cast on the validity of Miller's (carbohydrate-fermentation, lactic acid) theory, and more attention has been paid to the possible role of the organic portion of the enamel as the potential portal of entry. The evidence at present is that a civilized diet certainly appears to be one of the major factors in aetiology, though other factors, such as heredity, enter into it. Additional calcium will do no harm, but the evidence that calcium and vitamin D have any effect upon the disease, once the teeth have calcified, is not very striking. Overdosage with vitamin D is unlikely to cause any increase in the disease, so far as is known. Ingested fluorides do appear to have a marked inhibitory effect, particularly if absorbed while the teeth are calcifying. Large-scale experiments are at present being undertaken in the United States to assess the value of fluorides artificially added to the water supply.

### Complicated Labour

**Q.**—(a) What is the cause of extension of the legs in a breech presentation? (b) What is the treatment for a young primipara, fifteen hours in labour, head on pelvic floor, cervix two fingers dilated, when foetal distress is present? (c) What is the treatment of a primipara with a marked degree of pelvic contraction and heavy vaginal infection at term?

**A.**—(a) For reasons unknown, probably as the result of chance, the foetal legs sometimes become extended early in pregnancy, and it is the extension which causes the breech presentation, and not vice versa. This effect is mostly seen when the uterus has good tone, as in primigravidae. In most multigravidae, and in a few primigravidae, the uterus is sufficiently relaxed to allow the foetus to alter the attitude of its legs or even to allow spontaneous version with the legs extended. There is therefore much to be said for regarding extension of the foetal legs as "normal" and desirable when the breech presents in a primigravida. Indeed, in primigravidae if the foetal legs are not extended a diligent search should be made for another cause for the breech presentation, such as contracted pelvis or placenta praevia.

(b) If the baby's life is to be saved without undue risk to the mother the alternatives are: (1) lower-segment caesarean section followed by chemotherapy; (2) single or multiple incisions of the cervix followed by forceps delivery. The latter procedure is safe only when the cervix, although incompletely dilated, is extremely thin, and even then should be carried out only by an expert working in a fully equipped theatre. It

should always be borne in mind, however, that the occurrence of foetal distress in circumstances such as those described—that is, when the stress of labour has been so little as to make the onset of foetal distress unexpected—should raise doubts as to whether the foetus is normally developed. Before any treatment is decided on it is desirable in such cases to examine the foetus by x rays for evidence of spina bifida, etc. Other possibilities, such as looping of the cord round the neck or trunk, should also be kept in mind.

(c) It is not stated what sort of vaginal infection is in question. In the case of infection with trichomonas or fungus there need be little anxiety, because such organisms rarely, if ever, infect the upper genital tract. Apart from these, the only common infection in the lower genital tract is gonorrhoea. If the patient is not in labour, then treatment for the disproportion should be delayed a few days until treatment appropriate to whatever organism is present has been instituted and the infection is under control. If delay is impossible, then caesarean section is not contraindicated, provided the lower-segment technique is employed and chemotherapy is started immediately. The vagina might be disinfected as thoroughly as possible by washing out and painting with "Bonney's blue" immediately before operation, but the value of previous vaginal preparation has not been convincingly demonstrated and is not essential.

### Atopic Dermatitis

**Q.**—For five years a woman aged 43, otherwise healthy, has had seborrhoea sicca and an allergic dermatitis of her scalp, neck, arms, and shoulders. There is no demonstrable area of focal sepsis. She cannot tolerate any kind of soap or spirit and has been proved to be allergic to eggs, horses, and dogs. Most treatment seems to cause a flare-up, though a local calamine ointment does help to relieve the intense burning and itching. What treatment do you suggest?

**A.**—The diagnosis would appear to be between atopic dermatitis, contact dermatitis, and seborrhoeic dermatitis. That she has been proved allergic to eggs, horses, and dogs and has severe pruritus would suggest that it is an atopic dermatitis. Investigation and treatment would be by trial elimination of the common foods from the diet for six weeks, possibly a little longer. Scratch and intracutaneous tests are usually positive in this condition, but their value in tracing the offending allergen is doubtful. The most likely foods are egg, wheat, milk, and potato, in this order. Each food must be eliminated completely during the trial period. The age is in favour of a contact dermatitis, and patch tests would help in this condition. Location of the primary site might give a clue to the allergen. If the scalp were first involved it would suggest hair dyes, hair tonics, cosmetics, etc.; if the neck, an article of clothing, the dye in such article, etc. Symptomatically, the use of one of the new antihistamine drugs is well worth a trial. "Benadryl" in doses of 50 to 100 mg. might help, especially at night, owing to its tendency to cause drowsiness. "Nethisan" (pyranisamine maleate) is used in doses of 400 to 600 mg a day and is less likely to cause drowsiness.

### Constipation in an Infant

**Q.**—A male child aged 4 months, although in excellent condition, gaining weight, and contented, has settled down to one motion a week. The stool is normal in colour and consistency. Until the age of 6 weeks his bowels acted normally, then for about a month he passed slightly frothy stools, gradually changing to his present constipated routine. As the child is so well, what should I do about its condition?

**A.**—Although frequency of stools varies considerably in normal infants, the present interval is so long that it does suggest the possibility of Hirschsprung's disease. As the stools are normal in consistency and colour, it would be advisable in the first instance to try the use of a soap stick or vaselined glass rod inserted into the anus daily at the same hour, to see if a more frequent habit could be instituted. It would also be advisable to have a barium follow-through to elicit any radiological evidence of a congenital abnormality. It is inadvisable to use liquid paraffin or purgatives routinely at this age, and unless a congenital abnormality can be demonstrated it is unlikely that any surgical treatment will be required in the absence of distension or general symptoms.

## NOTES AND COMMENTS

**Ringworm of Scalp.**—Dr. J. T. DUNCAN (Department Medical Mycology, London School of Hygiene and Tropical Medicine) writes: Col. W. H. Crichton (Oct. 18, p. 640) describes his successful treatment of a number of cases of head ringworm in children in North Devon by means of a saturated solution of potassium permanganate. The species of ringworm fungus concerned was not mentioned, but readers may assume that it was the common parasite *Microsporum audouinii*. The experience of nearly half a century leaves no doubt that infection of the hair by *M. audouinii* is extremely difficult to cure by any local treatment except epilation by the use of x rays. On the other hand infection of the hair in children by the alien and less well adapted parasite *Microsporum canis* is known, with a few exceptions, to yield readily to topical treatments. In South Devon the predominating dermatophyte found in tinea capitis of children is *M. canis*, and this is true also of parts of North Devon. It cannot too strongly be urged that the identity of the infecting dermatophyte should be established before treatment of tinea capitis is undertaken, and it is especially important that the name of the causative fungus should be stated in connexion with reports on the treatment of head ringworm. (Since I wrote the accompanying note I have consulted our records and found that between October, 1946, and May, 1947, we identified 37 cases of infection by *Microsporum canis* from specimens of hair of children in the Barnstaple area of North Devon sent to us by Dr. W. Crichton.)

**Food Allergy.**—Dr. JOHN FREEMAN, of the Wright-Fleming Institute of Microbiology, writes: A well-known London physician has called my attention to the question and answer on food allergy (Oct. 11, p. 598). He says your answer is not good, and I quite agree with him. The question as stated gives the presumption that the child is egg-sensitive. Though that is quite unlikely to be the whole of the story, it is important to know whether or not this presumption is correct. Trial dieting is very fallacious and has many disadvantages. The way to test is by a skin test with egg protein; this is quite reliable for finding a positive or negative to that particular sensitivity. This test is, however, only one item in the necessary investigation. If the child is sensitive to egg, and this is playing a big part in producing symptoms (and that is a big assumption), the child can be desensitized with egg protein, though this is not a job for the inexperienced. It is probably preferable with a child of that age that egg should simply be avoided in the diet. Lastly, doping a patient with "benadryl" has its disadvantages, though it may be a useful temporary expedient in some cases. I agree that immunization with diphtheria toxoid and pertussis vaccine is very unlikely to have any bad effect on this child.

**"Pen Friends" for the Old.**—Miss M. A. PRATT ("Hillview," Bryants Bottom, Great Missenden, Bucks) writes: In spite of schemes for the care of our aged and chronic sick folk, it seems inevitable that for years to come most of them will spend their days in institutions, where too often they are completely cut off from the outside world. . . . For some years the Pen Friends' Guild has provided correspondents for inmates of L.C.C. institutions who never get a letter. The service has been much appreciated and is being extended to other counties. Offers of help, either as correspondents or as county organizers, would be very welcome.

**Pink Disease.**—Dr. G. M. B. HALES (Sydney, New South Wales) writes: In the *Journal* of June 21 (p. 911) a correspondent asks for advice about a case of pink disease. During the past ten years both at the Renwick Hospital for Infants, Sydney, and privately I have treated these patients with intramuscular injections of Vit. E extract and vitamin B<sub>12</sub>, 15 mg., twice weekly. In the majority of cases, and particularly if seen early, there is marked improvement and loss of the characteristic irritability after the third or fourth injection. It is rarely that more than twelve injections are required and recovery is generally complete in about eight weeks.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 29 1947

## PROTECTION OF PRACTICES SCHEMES REPORT OF THE LONDON SCHEME

When it seemed possible that the country was likely to be involved in war a scheme was evolved for the protection of the practices of the practitioners who might be called upon to undertake national service and the treatment of the patients attached to those practices. The scheme was adopted for the administrative County of London at a meeting of London insurance practitioners held at B.M.A. House on Dec. 20, 1938. The London Insurance Committee were asked to administer the scheme in their area, and the committee decided that they would willingly co-operate as regards the administration of it as part of the scheme which related to National Health Insurance practice.

### The London Scheme

All medical practitioners in London were invited to participate in the scheme and, as an indication of their assent thereto, to enter into an agreement subscribing to the terms of the scheme, the administration of which was entrusted to a committee which was known as the Local Emergency Committee and was representative of the interests of practitioners engaged in all classes of practice. The scheme was put into operation in London immediately on the outbreak of war. Practically all the practitioners engaged in National Health Insurance practice in London ultimately became signatories to the scheme, which operated in London on an entirely voluntary basis. The suggestion of making it compulsory was considered, but it was decided not to adopt that course.

The scheme had two objects: (1) to protect the practice of the absent practitioner, and (2) to provide treatment for his patients during his absence. A notice was exhibited at the surgery of each absentee practitioner whose practice was conducted under the Protection Scheme stating that fact and advising patients to apply to any local practitioner and to present to him their medical cards. The names of the nearest practitioners to the surgery of the absentee practitioner were given. The practitioner applied to accepted the insured person provisionally and forwarded the acceptance to the insurance committee for registration. There were created what were known as "provisional lists" for acting practitioners. On an absentee practitioner undertaking national service 50% of his National Health Insurance remuneration was paid to him, and with the other 50% a fund was created from which acting practitioners were remunerated.

The practice of an insurance practitioner in London ordinarily extends two miles from his surgery (north, south, east, and west), with the exception that the River Thames forms a natural line of demarcation. This gives a "practice area" of 124 square miles. It will be realized from this that insured patients on the list of an absentee practitioner were not restricted in their choice of an acting practitioner to one practising near to the surgery of the absentee but could choose any acting practitioner within the radius mentioned. Patients on the boundary of a "practice area" were free to select an acting practitioner two miles from such boundary, and the area within which some patients of an absentee practitioner might conveniently find an acting practitioner was thus increased from 124 square miles to 50 square miles. It was thought at the beginning that the practice of an absentee would fall to be conducted by, say, four or six practitioners within the immediate vicinity of the surgery, but the working of the scheme demonstrated this theory to be without foundation, for, in view of the wide range, patients of an absentee became distributed

among a large number of practitioners. As examples of this, it may be mentioned that in one case 1,322 insured persons on the list of an absentee were distributed among 79 acting practitioners, two of whom between them took 675 of the number mentioned. In another case, although the acting practitioner was actually "sitting" at the surgery of the absentee—in this case a deceased practitioner—239 patients who were not accepted by the acting practitioner were distributed among no fewer than 53 other acting practitioners.

The administration of the London Insurance Committee proved of extreme importance and of great value in the protection of an absentee's practice inasmuch as the possession of a medical card, although many years old, was usually tangible evidence that the patient was an insured person on the list of the absentee and entitled to obtain treatment from him. It was in this respect that the administration of the National Health Insurance side of an absentee's practice was so much easier to provide for than the private side of the practice, for the production of the medical card at once informed the acting practitioner of his liability to accept the insured person as a patient of the absentee.

The scheme provided not only for the conduct of practices of practitioners who were absent from their practices on national service but also for the conduct of practices of deceased practitioners, both absentee and acting, and of practitioners who were temporarily unable to carry on their practices. The total number of practitioners who went on service and took advantage of the scheme was 450, and during the period of operation the staff of the London Insurance Committee dealt with approximately a quarter of a million acceptances and the same number of deletions. During the peak period it was quite a common thing for the acceptances to number anything between twenty and fifty thousand each quarter. In addition to the 450 cases referred to of practitioners absent from their respective practices on national service, the scheme was applied in the cases of seven practitioners who were killed by enemy action at home and fifteen others who died. Cases of temporary incapacity in which the aid of the scheme was invoked numbered 20, and the grand total of practitioners (or their dependants) who took advantage of the scheme was 492. It may be stated that during the absence of a practitioner no insured person was removed from his list who would not have been removed had the practitioner himself been in the practice. It is true that the lists of absentees decreased, but this was due to the fact that lists moved mainly by way of deletions, there being very few acceptances made on behalf of absentee practitioners.

The scheme was an undoubted boon to the dependants of practitioners who died. During the war it was impossible to sell a practice to advantage, and by placing the practice under the scheme it was possible to await a more favourable opportunity for the disposal of the practice; in the meantime the dependants continued to derive 50% of the income. As a proof of this it will suffice to say that during the period (five years) in which one such practice was conducted under the scheme the insurance committee paid no less than £4,372 to the dependants of the deceased practitioner, and a similar sum was paid to the practitioner who acted as the principal deputy in respect of the provisional acceptances made by him.

### Separate Pools

An interesting development after a short time was the creation of what were known as "separate pools." The idea had as its genesis the practice of two partners, the junior of whom was called up for service. The senior partner remained

at home and carried on the work of the practice. The practice was operated under the scheme, and by the creation of a separate pool for the particular practice the acting practitioner (in this case the senior partner) was spared the necessity of accepting his absent partner's patients. The London Insurance Committee staff were also relieved of the necessity for registering and crediting acceptances and the issue of new medical cards, thereby saving not only time and labour but also material. The arrangement proved so successful that it was afterwards extended to practices where the absentee practitioner was fortunate enough to be able to secure the services of a full-time deputy.

The method of working these separate pools was as follows. The patients were given the opportunity of continuing to go to the surgery of the absentee practitioner, where they were seen by the practitioner acting as the principal deputy, but they were also given the opportunity of going to another acting practitioner if they wished. Half of the absentee practitioner's remuneration was paid according to his directions, while the remaining half constituted the separate pool. From that payment was made, as a first charge, to any other acting practitioner who accepted patients of the practice; the authorized charge for administration was deducted and the balance paid according to the directions of the absentee practitioner. In this way the practice continued to receive approximately 95% of the total remuneration due from the insurance committee.

Financially, the broad basis of the scheme was that 50% of an absentee practitioner's remuneration was paid according to his directions while the remaining 50% was carried to the credit of the London "pool." From that pool the acting practitioners were remunerated in proportion to the number of provisional acceptances made by them, and it is interesting to note the following unit value per annum.

Year	Rate per Unit
1939 (September to December—four months only)	8s. 1-376d.
1940	11s. 9-253d.
1941	11s. 8-367d.
1942	9s. 11-404d.
1943	8s. 5-447d.
1944	8s. 4d.
1945	8s. 3-815d.
1946	15s. 0-569d.
1947 (January to June—two quarters only)	7s. 7-432d.

The total amount paid to absentee practitioners was £329,258 9s. 11d., and that paid to acting practitioners was £319,890 1s. 3d. The administration costs were comparatively small, and a deduction of 24% per quarter was generally sufficient to provide for the cost of administration. In respect of two quarters only was a deduction of 5% made, but on no occasion did the deduction exceed that figure.

The scheme was officially brought to an end on Sept. 30, 1947.

While the experience of the administration of the scheme might, and no doubt would, lead to modification being made in any further effort of this description, it cannot be gainsaid that the scheme, so far as National Health Insurance practice is concerned, accomplished all that it was designed to do, and that it worked satisfactorily and to the advantage of those who participated in it, either as absentee or as acting practitioners, and also the insured persons. Whether it is humanly possible to devise a scheme which will solve any and every problem is doubtful, as so much depends on the good will, tolerance and helpfulness of all concerned.

#### REPORT OF THE KENT PROTECTION OF PRACTICES COMMITTEE

The Kent Branch prepared the scheme based on the model issued by the Association. There were some modifications, the most important being (1) the arrangement for the payment by the insurance committee of the amount due (50%) on N.H.I. fees to the legal representatives of the absentee doctors, and (2) the accountancy arrangements on private fees whereby the acting doctor retained 50% of the fees and paid the balance to the bureau, except in the case of partnerships, where the partner of the absentee practitioner was not required to supply any records of any private patient who would normally receive treatment from the absentee partner. Mr. Lloyd, clerk of the Kent Insurance Committee, acted as the administrative officer

of the scheme, and 47 meetings of local committees were held to deal with questions of its working. The gross amount disbursed was £209,845.

While the scheme provided that a partner of an absentee practitioner was not required to keep and supply records in respect of any private patient who would normally receive his treatment from the absentee partner, no special provision was made for insured persons on absentee partners' lists. The committee decided that the lead given in the case of private patients should be applied to these insured persons. Therefore acting partners were notified that it was not necessary for them to accept the medical cards of insured persons on the lists of their absentee partners, that a separate pool would be formed from which other acting doctors accepting any of the insured persons from the list would first be paid on the basis of two units for each person, and that the balance would be paid to the acting partner.

The evacuation of the coastal towns and the consequent serious effect this had on medical practices was considered by the committee, who decided that practitioners who had to leave the area should be considered as absentee practitioners provided they took appointments in other areas. In all cases practitioners met this condition. The majority of those who remained in the coastal towns were appointed to the Emergency Medical Service, and the committee were able to give material assistance in obtaining better financial conditions for them than those originally arranged. The committee acted as the agent of the Ministry of Health in the collection of moneys, and to meet the special circumstances suggested to the E.M.S. practitioners the formation of "town pools." This method of the collection and distribution of fees was agreed by the practitioners and provided an equitable distribution of funds. The aggregate amount of fees (N.H.I. and private) dealt with under this arrangement was £70,624.

It was possible for arrangements to be made by the bureau for carrying on practices by other acting doctors where a practitioner became ill, was interned, or died. Twenty-nine practices were carried on during the temporary incapacity of the practitioner; four doctors who were interned for a short time were assisted under this arrangement; and thirteen death vacancies were covered until such time as the executors were able to dispose of the respective practices.

The accounts collected by the bureau were few in number and small in amount. This is accounted for by the fact that the bureau was not asked to collect accounts until all efforts on the part of the doctor giving treatment to recover his fees had been exhausted. Every absentee doctor on his return to practice was supplied with a detailed return giving the names of acting doctors and the total amounts of private fees sent by them to the bureau on his behalf. The total number of signed agreements received was 768, though these were not all in force at any one time as there were day-to-day changes in the number of doctors. It is estimated that the number received represented approximately 90% of the profession in the area. The total number of practices placed under the scheme was 313 (174 on service, 13 on national service, 47 coastal practitioners, 33 E.M.S. practitioners, 29 sickness cases, 4 interned practitioners, 13 death vacancies), and the highest number at any one period was 208 in 1942.

A number of letters have been received from doctors expressing appreciation of the availability of the scheme and the benefits received by them through its application in their cases. At the meeting of the committee on June 24, 1947, a presentation of an inscribed silver salver was made to the chairman, Dr. G. R. F. Stilwell. The committee placed on record their thanks to the clerk (Mr. J. H. Loyd) for his administrative work in the practical application of the scheme.

The report of the committee concludes: "The committee are of opinion that despite the failure of some acting practitioners to observe the contract the scheme has been of material assistance to absentee practitioners and has been most useful in maintaining a service. Some of the practitioners who refused to sign the agreement have evidently felt there was a need for it as they have made payments to absentee doctors either direct or by using the bureau to re-transmit their cheques. They have also asked the insurance committee to re-transfer the insured persons they have accepted."

## HEARD AT HEADQUARTERS

### Promotions

eldom if ever can there have been so many promotions of medical officers listed on a council's agenda as appear on the agenda of the London County Council for Nov. 18. They number 57—all men. Four are promoted to be senior physicians at a maximum salary of £1,800; 13 to be senior physicians commencing salary of £1,500; 4 to be surgeon specialists at a maximum salary of £1,800; 12 to be surgeon specialists at commencing salary of £1,500; 7 to be physician superintendents at a maximum salary of £1,800, and 6 at a commencing salary of £1,700; 10 to be assistant senior physicians commencing salaries from £1,050 to £1,300, and one to be assistant surgeon specialist at a commencing salary of £1,000. 24 of the cases of senior physicians, surgeon specialists, and assistant senior physicians £50 is added to the yearly salary because the persons concerned will be acting as deputies to superintendents. The recommendations are in conformity with an earlier proposal of the Council to provide adequate specialist staff in its hospital service.

### Certification of the Blind

The certification of the blind or partially blind is not the simplest matter it might appear to the non-ophthalmologist. Mr. Stenhouse Stewart told the Royal Society of Medicine on the other day of two men who, with doubtful justification, had enjoyed protected employment as certified blind men in the lean years before the war. When the war offered more remunerative employment they both sought and obtained it in a more active capacity. After the war they applied for recertification. One of them was refused by one examining ophthalmic surgeon; the other was accepted by another. The first man was dissatisfied at his rejection and requested the services of a referee, and the authority itself decided to seek the referee's opinion in the second case. As a result, both opinions were reversed; the man who had been refused recertification was readmitted, and the man already readmitted was rejected. It is easy, of course, to blame the examiner, but Mr. Stewart pointed out, the examiner is required to reach an absolute judgment on a relative matter, based on uncertain data, with the attached responsibility in some cases of either authorizing the disbursement of £3 a week or more for the next fifty years from public funds or of withholding that support from a man so seriously disabled as to have poor prospects of regular employment. The decision is usually reached at a single examination on evidence of visual impairment exhibited by the patient. The medical man who accepts the responsibility of forming this opinion may have received no special instruction for the work and is unlikely to have an extensive knowledge of the requirements of various types of employment.

### Colonial Medical Service Salary Scales

The urgent need for the revision of the salary scales of the Colonial Medical Service was apparent at the last meeting of the Council. The Council considered reports from overseas branches on the difficulties that officers of the Colonial Medical Service were experiencing. The whole of the Colonial Service is, of course, affected by the rise in the cost of living in the Colonial territories, which in some cases is even greater than in this country. While the Council recognized that commissions had been appointed to review the salaries of the Civil Services in some parts of the Empire, it considered that the salaries of the medical officers should be related to the remuneration of practitioners in this country, and the Secretary of State for the Colonies has therefore been informed that the Council proposes to raise the question of the revision of the existing salary scales in the light of the findings of the Spens Committees. In the meantime, however, the Council feels that action must be taken to relieve the financial circumstances of Colonial medical officers, and it has therefore requested that an immediate overall percentage increase, similar to the second

interim revision of the Askwith Scale, be made to the salaries of these officers. The Secretary of State has been asked to regard the matter as one of extreme urgency, and the Council will consider the position again at its next meeting, taking into consideration the reply received to its interim proposals.

### Many Questions

The Psychological Medicine Group of the Association had a conference the other day the agenda of which was almost entirely a question paper. Members of the Group had sent in 24 questions in advance, all of them bearing on the subject of psychiatry and the National Health Service. However, Dr. W. Rees Thomas, of the Mental Health Division of the Ministry, gave a preliminary address, and when he had finished very few of the questions remained to be put, even though the answer in some cases could be at present only a quotation from the Act, which may leave quite a lot to the imagination. There is evidently among psychiatrists a good deal of anxiety about the future liaison of regional and local mental health services in regard to certification and early treatment of mental illness, ascertainment and supervision of mental defectives, and child guidance. How many local-authority services will continue in operation and how many will be handed over to the regional board? Will local authorities continue to employ their own psychiatrists? In one way psychiatrists are favoured over and above other specialists, for it is laid down that of the 15 medical practitioners on the Central Council two shall be selected for their knowledge of mental illness and mental defectiveness, and on the regional boards there must be members with experience in mental services.

### Stolen Drugs

Chief constables are frequently having to ask the B.B.C. to broadcast messages about drugs or poisons stolen from doctors' cars. A short time ago the Home Office therefore asked the Council of the B.M.A. if it would take steps to urge doctors to lock their cars when they leave dangerous drugs in them, or, alternatively, to remove the drugs from them. Obviously doctors would like to do all they could to stop this petty thieving, if for no other reason than that it seriously interferes with their work. But the question arises whether locking a car is really an adequate safeguard. Locking a car should, of course, deter the casual pilferer, the spiv who pinches something because he has got nothing better to do. But for the thief who takes his job seriously a locked car is child's play, because he is, we understand, usually well provided with the keys of all makes of cars, their locks being standardized. It might even be argued that a locked car would suggest to the thief that there was something in it worth stealing. However inadequate, locking a car is, nevertheless, some safeguard, and we would urge doctors not to forget this even though they may leave their cars only for a short time.

There is another side to this which perhaps has not yet been considered, and that is that a "Doctor" sign on a car does attract the attention of thieves who may be peddling drugs for addicts. The Council of the B.M.A. has decided that it is proper for "Doctor" signs to be affixed to cars, and we agree that there is much exaggeration in the belief that such a sign would act as personal advertisement. But it does advertise the fact that there may be something in the car worth stealing.

### Prescribing Dangerous Drugs

Another matter that is worrying the Home Office is the fact that many medical practitioners are now ordering dangerous drugs and poisons by telephone. This is contrary to the Dangerous Drugs Regulations, 1937, which lay down clearly that no authorized seller of poisons is allowed to supply a dangerous drug unless he receives a prescription in writing signed and dated by the person giving it. The use of the telephone saves a lot of time, and in these days when medical men are so overworked it is understandable that they should try to save time in any way possible. But apart from the obvious dangers of such a practice medical men should recognize that they put the pharmacist in an embarrassing position. For fear of losing a customer the pharmacist may feel disinclined to

do what is clearly his duty, and if he knows the doctor well he may naturally feel inclined to ease his burden by this irregular practice.

According to the *Pharmaceutical Journal* (July 12, 1947) the Home Office is also concerned by the fact that drug addicts are making greater use of forged prescriptions. There has apparently been no instance in which a drug addict has ordered a prescription by telephone, but no doubt they will jump to this dodge if they know it is becoming an increasing habit amongst medical men. We would therefore urge doctors to be punctilious in meeting the requirements of the Dangerous Drugs Acts.

## FACULTY OF OPHTHALMOLOGISTS

At the Council Meeting on Oct. 10 it was reported that the Medico-Political Standing Committee had submitted a memorandum to the Evidence Committee, sitting under the chairmanship of the President of the Royal College of Surgeons, on the remuneration of consultants and specialists.

The local authorities would not accept a salary scale for orthoptists approved by the Faculty or any other professional body, but asked for a properly negotiated scale between employers and employees. It was, however, noted that the Joint Negotiating Committee's salary scale was acceptable to the Faculty, and therefore it was decided to take no further action.

The question of standards of vision for orthoptic students was reviewed and the following resolution adopted:

Visual acuity should be 6/9 corrected in each eye, with full binocular vision. It is undesirable to have more than 7 D refractive error in any meridian, but such cases could be accepted at the discretion of an ophthalmic surgeon.

A letter had been received from the Ministry of Education requesting the Faculty's opinion on plastic lenses for school-children. It was decided that, in view of the present state of development of plastic lenses, particularly their softness and their liability to scratch, the Council did not consider that they were a practical proposition for universal use at the moment.

Following correspondence with a joint committee set up by the B.M.A. and the Pharmaceutical Society to compile a national formulary suitable for use in the National Health Service, the Faculty nominated three representatives to serve on a subcommittee to consider the draft section of the formulary concerning ophthalmology.

The attention of the Faculty Council was called to the fees for school ophthalmic work from two sources. In view of the fact that the scale of fees for all local-authority work had been negotiated by the B.M.A. for all consultant and specialist work, it was decided that no further action could be taken at the moment.

## REGIONAL HOSPITAL BOARD APPOINTMENTS

The Minister of Health has made the following appointments to Regional Hospital Boards:

*Leeds.*—Mrs. N. Fienburgh, Deputy Chairman of the Health and Housing Committee of Bradford Corporation, to fill the vacancy caused by the resignation of Councillor A. Walker.

*Birmingham.*—Alderman W. T. Bowen, Chairman of Birmingham Public Health Committee, to fill the vacancy caused by the resignation of Mr. D. J. Evans owing to pressure of other work.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils.*—Barnsley, Gateshead.

*Metropolitan Borough Councils.*—Fulham, Hackney, Poplar.

*Non-County Borough Councils.*—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

*Urban District Councils.*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs.*—Motherwell and Wishaw.

## Correspondence

### Basic Petrol

SIR.—Here is some more of the evidence Dr. L. R. Atkinson (Nov. 8, p. 113) asks you to collect. (1) In the summer of 1946 I was obliged to ask for more professional petrol before the period ended, and got it. (2) This summer I expended my professional and basic ration one month before the end of the period I applied for more, and got it. (3) At the beginning of the present period, when making the usual application, I drew attention to the fact that I had had no holiday, that I had made two Sunday outings using about six gallons of my basic, that I had subsidized my professional allowance from my basic and had nevertheless been a month short. In view of this I applied for a bigger allowance. I received about 20% less for the next six months. I doubt if I can run for much over three months without reapplying.—I am, etc.,

Teignmouth, Devon.

JOHN A. TIPPEL

SIR.—When I applied for my petrol ration I asked for half the amount of the previous allotment, because, as I explained, I had given up some of my work. This application was cut by 10%. Evidently the fiat has gone forth that we are all criminals and that every application is to be cut.—I am, etc.,

S. Godstone, Surrey.

H. E. GIBSON

### National Health Service

SIR.—My letter (Nov. 1, p. 100) has drawn forth a very rapid and warm response from Mr. A. Staveley Gough (Nov. 8, p. 112), who accuses me of issuing propaganda in favour of a full-time salaried State service. Not so fast, Mr. Gough. You cannot by misrepresentation dismiss the viewpoint held by hundreds of doctors who, like myself, practise in colliery areas. On the contrary, I agree rather with the views expressed in a letter from Dr. G. T. Allerton (p. 112). The latter points out that if the National Health Service is implemented in July, 1948, the work of G.P.s will be approximately doubled, and the result will be chaos. Yet I am expected to thank Mr. Gough and his colleagues on the B.M.A. Council for having voted against fixed hours of duty.

When I opined that the genuine G.P. sees in the National Health Service a chance of release from the bondage of a 24 hours-a-day shift, I should have underlined the word "chance". Now is the time for all G.P.s to make it quite plain to the Minister of Health that they are desirous of initiating the principle of fixed hours of duty and leisure, in order that efficiency and opportunity to practise medicine may be enhanced. If we do not do this, the weeds in our "Slough of Despond" will grow even more tangled, and where once efficiency and enthusiasm flourished there will remain instead black despair and apathy.

With reference to Mr. Staveley Gough's remarks about the failure of G.P.s to manage a large practice being due to lack of ability and personality, I would like a more concise definition of what is meant by "ability." Does he mean the ability to see a panel or "club" patient out of his consulting-room within one minute? Mr. Gough, by the exercise of his "personality" is able to persuade his colleagues to give continuity of treatment to his large number of panel patients, in order that he may find time to sit on the Hospitals, Building, and Public Relations Committees of the B.M.A. By further dispensation of doctors his "personality" he is able to make his patients feel that the visiting doctor is chosen by, and is closely in contact with, their own doctor and not any other doctor chosen by that remote body the "State." Really, Mr. Gough! I would like to see myself as a pupil to you in order to learn how this "personality" can be developed. Apparently I am very much lacking in that department. On the occasions when I have found the locumtenent on behalf of an absent colleague I have found the continuity of certification and not treatment was the primary concern of the patient. When, reciprocally, I have left a practice for a day or two, I have found on my return the patients undergoing active treatment have refused to see a locum, but have preferred instead to await my return.

I have already intimated that, in my opinion, the time is not yet opportune for the introduction of a complete National Health Service.

Health Service. But of this I am certain: there will eventually be a comprehensive State service whether the diehards of the B.M.A. desire it or not, and it is my contention that the seeds of better working conditions and status for the G.P. should be sown now. A reasonable daily spell of duty is the *sine qua non* of such betterment. Otherwise we will continue to see young men who began general practice with enthusiasm degenerating into disinterested automata, while house-surgeons and house-physicians will continue to earn miserable pittance in hospitals rather than stigmatize themselves with the odium associated with general practice. Therefore, Sir, as I find myself being pushed nearer and nearer towards the brink of the abyss, I again raise my somewhat enfeebled voice in a plea for all-round improvement in the lot of the G.P.—I am, etc.,

N. Wingfield, Derbyshire.

H. FIRMAN.

### The N.H.S. and Compensation

SIR,—I see that Dr. Dain stated (*Supplement*, Nov. 8, p. 107) that compensation for doctors' practices had not been discussed with the Minister, as they had had no instruction from the Representative Body that it would be willing to accept the loss of goodwill which compensation would involve. As it has been previously stated that these negotiations do not bind the medical profession to any course, I cannot see why this most important point has not been discussed. Surely there is no harm in knowing what the Government has in mind? Everybody in practice must be interested in compensation and how it is to be applied. As it is we must remain in the dark even when the results of the negotiations are revealed.

The Representative Body has now turned down any scheme for working hours in the National Health Service and also stopped any discussions on compensation. It is pertinent to ask whom this body represent. I have the greatest admiration and gratitude to the doctors who are giving up their time on the apparently endless committees and subcommittees, and, while they may represent some of the profession, I would point out that they must not allow their outlook to become so narrow that they cannot appreciate differing views. Are our representatives, in not discussing every aspect of this scheme, acting in the best interests of the profession at large?—I am, etc.,

Barnsley, Yorks.

D. W. MAYMAN.

### N.H.S. for the Old?

SIR,—In *The Times* of Nov. 6 Mr. Griffiths, Minister of National Insurance, is reported as having said: "The self-employed man would get his contribution card . . . and would have to stamp it each week. . . . In return the self-employed man or woman would receive sickness benefit. . . . If he was over 65 or a woman was over 60 at the beginning of the scheme, he or she would not be in the scheme at all." Does this mean that these people will be excluded from medical service under the National Health scheme? If so, this scheme cannot be described as covering 100% of the population.—I am, etc.,

London, S.W.10.

A. E. BERYL HARDING.

\* The benefits of the National Health Service are not dependent on any insurance qualification.—Ed., *B.M.J.*

### Working Day in the Services

SIR,—Being neither in the position of the F.O. (Sept. 13, p. 66) and F./Lieut. (Oct. 18, p. 92) who, quite understandably, refrain from giving their names, or of the Wing Commander who, equally understandably, has no hesitation in supplying his (Nov. 8, p. 113), I feel in a more favourable position than either party to contribute to this subject. For over six years I (a) satisfied myself that the station water supply was pure and adequate; (b) did the same for milk and other food supplies, and so on. I did a great deal more. I delved into such dark mysteries as the blocking up of the W.A.A.F. water-closets, a matter which not only involved my inspection and report but an independent inspection and report from the sanitary corporal from group headquarters, a visit from the wing commander himself, a conference with the C.O. of the station, the visits and reports of various W.A.A.F. officers, and the visit and report of an itinerant nursing sister. I accepted the fact that such matters were part of my duties as a medical officer. But ought they to have been?

Was it to the benefit of the Service or of the taxpayer that a qualified medical practitioner should be employed at a salary of some six or eight hundred pounds a year in doing duties which were well within the scope of a sanitary corporal?

Now I do not expect Wing Commander R. E. W. Fisher to concern himself about the taxpayer or to devote his energies to working out schemes to save medical man-power. These things are obviously none of his business. But it seems to me wrong that just because he himself is willing to forget he was trained to be a doctor and is content to occupy himself with a mass of extraneous detail he should assume that others ought to be content to do the same. Clearly, it is desirable that the best possible use should be made of the special knowledge which the medical officer possesses, and this quite definitely is not being done. And there seems no reason why it should not be done. It is merely necessary to cut down the number of medical officers until their days are fully employed on duties of a purely medical nature. As regards the Air Force, medical officers can be made exceptionally mobile, and there is no reason why one medical officer should not have six or more stations under his care and still provide as efficient a medical service and be as readily available in case of sudden illness or accident as it would be reasonable to expect in civilian life (It is of course natural that Service chiefs should prefer to have a medical service standing by, night and day, to deal with any possible emergency, but this is a luxury that no member of the public enjoys, and should not be allowed.)

The only difficulty that I see is how to initiate such a change. It is clearly a matter which is unlikely to receive attention if brought forward by a junior officer, nor can one see any likelihood of officers of higher rank interesting themselves in such changes. The only hope seems to lie in the initiative of some distinguished and disinterested member of the profession outside the Services who is concerned with medical education and who is not content to see the long and expensive training of the qualified medical practitioner frittered away in this manner and subjected to such abject abuses.—I am, etc.,

NIGEL LORING.

London, S.W.7.

Late Squadron-Leader, R.A.F.V.R.

SIR,—It was obviously only a question of time before an answer on the lines of Wing Commander R. E. W. Fisher's (Nov. 8, p. 113) was made to F.O.'s and F./Lieut.'s reasonable complaints. It was the standard answer during the war, when there was admittedly much more justification for urging medical officers to undertake all the duties he enumerates, but even then it was sometimes impossible to keep oneself usefully occupied for more than a few hours a day. There is, for instance, a limit to the number of times one can profitably test the purity of an adequate water supply from strictly supervised mains, and similar arguments apply to the other duties. Further, there are sanitary officers, welfare officers, education officers, and catering officers to perform many of them, to say nothing of the padre.

The time should be past when the medical officer is expected to perform every job from clerk and bottle-washer to bar officer in the mess. No doubt he often can, and sometimes should, bear a hand outside "medicine" as such, but that is no reason for misapplying his training and side-tracking his special interests. One cannot turn a clinician into a combination of epidemiologist, public-health officer, psychiatrist, and administrator simply by giving him a commission.—I am, etc.,

LATE SQUADRON-LEADER, R.A.F.V.R.

SIR,—The point of this discussion, and possibly the spirit in which it was raised, would appear to have eluded Wing Commander R. E. W. Fisher (Nov. 8, p. 113). The matter is one of under-employment and not a "bind" against mis-employment. The importance of preventive medicine and sanitation is rightly stressed, and a high standard in this can be maintained by a sanitary round once or twice monthly. To assume that we neglect this and are ignorant of first aid is unwarrantable and a little unkind.

The sole criterion should be how and where the young doctor can best serve his country and discharge his obligations under the N.S.A. The contention that this particular pump is overmanned would appear to be unshaken.—I am, etc.,

F.O.

**H.M. Forces Appointments****ROYAL NAVY**

Acting Surgeon Lieutenants H. R. Malloes and S. D. Walsh to be Surgeon Lieutenants.

**ROYAL NAVAL VOLUNTEER RESERVE**

Temporary Surgeon Lieutenant G. M. Pearson has been transferred to List I of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenant J. F. F. Smith has been transferred to List I of the permanent R.N.V.R.

Temporary Acting Surgeon Lieutenants H. F. Hills, T. D. Hanraity, and A. A. R. Meek to be Temporary Surgeon Lieutenants.

Probationary Temporary Surgeon Lieutenants D. G. James, W. W. McPhail, and S. S. Meighan to be Temporary Surgeon Lieutenants.

**ARMY**

Colonel (Acting Major-General) J. R. N. Warburton, M.C., late R.A.M.C., to be Temporary Major-General.

Colonel R. A. Austin, M.C., late R.A.M.C., having completed four years in the rank, is retained on the Active List supernumerary. Major H. R. Edwards, late R.A.M.C., has been restored to the rank of Lieutenant-Colonel on ceasing to be re-employed.

Major F. P. Lauder, late R.A.M.C., retired and re-employed, has ceased to be employed on account of disability, and has been restored to the rank of Lieutenant-Colonel.

**ARMY IN BURMA RESERVE OF OFFICERS**

To be Lieutenants: T. Maung and M. M. Gyi.

**Association Notices****AREAS OF BELFAST AND NORTH-EAST ULSTER DIVISIONS**

Notice is hereby given by the Council to all concerned:

I. That the area of the Belfast Division be redefined as follows: The City of Belfast; that part of County Antrim south of, but excluding, Toonbridge, Ballymena, Carnlough; eastern part of County Down.

II. That the area of the North-east Ulster Division be redefined as follows: That part of County Antrim north of, but including, Toonbridge, Ballymena, Carnlough; the eastern part of County Londonderry.

Any member affected by these proposals and objecting thereto is requested to write to the Secretary of the Association by December 29, 1947, stating the objection and the ground therefor.

CHARLES HILL,  
Secretary

**SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH**

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

**Conditions of Award: Applications**

Applications for scholarships must be made not later than Friday April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

**Branch and Division Meetings to be Held**

CLEVELAND DIVISION.—At Coatham Hotel, Redcar, Thursday Dec. 4. B.M.A. Lecture by Mr. A. Lawrence Abel: Some Common Diseases of the Rectum and Anal Canal. Illustrated by cinematograph pictures. Lecture to be preceded by supper at 7.15 p.m.

GOOLE AND SELBY DIVISION.—At the Lodge, Smith, Thursday, Dec. 4, 8 p.m., Paper by W. N. Pickles: The Country Doctor.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, Dec. 2, 5 p.m. Dr. Robert Foster The Medical Witness.

MID-ESSEX DIVISION.—At Chelmsford and Essex Hospital, Sunday, Dec. 7, 10 a.m. Dr. Sleigh Johnson and Dr. Charles Warren Allergic Diseases.

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Aston, Wednesday, Dec. 3, 8.30 p.m. Paper by Mr. L. H. Backache and Sciatia.

STOCKTON DIVISION.—At Stockton and Thornaby Hospital, Barnfield Lane, Stockton-on-Tees, Monday, Dec. 1, 8.30 p.m. Paper by Mr. Harvey Evers.

WESTMINSTER AND HOLBORN DIVISION.—At St. Francis Hall, Caxton Street, London, S.W., Thursday, Dec. 4, 7.30 p.m. Meeting. Dr. R. W. Durand: Common Difficulties in Practice.

**Meetings of Branches and Divisions****NORTH DEVON (BARNSTAPLE) DIVISION**

At a meeting of the Division on Nov. 11 the following resolution was passed:  
 "That this Division of the B.M.A. is gravely concerned at the lack of consultation with the profession by the County Medical Officer in drawing up his scheme. We are further concerned at the lack of representation of the profession, particularly the general practitioners in active practice, on the Health Committee of the Devon County Council."

LONDON SATURDAY DECEMBER 6 1947

## STREPTOMYCIN AND TUBERCULOUS MENINGITIS IN CHILDREN

### PRELIMINARY NOTE

BY

ROBERT DEBRÉ ST. THIEFFRY ED. BRISSAUD AND H. NOUFFLARD

(From the Clinique Médicale des Enfants, Hôpital des Enfants Malades, Paris)

It is neither usual nor generally desirable to publish work on a new treatment before proof of its effectiveness and a knowledge of its limitations have been obtained. But the problem of tuberculous meningitis and of the first treatment known to have any effect on the disease is so important that it seems legitimate to draw attention to our preliminary trials, if only to point out our mistakes to our colleagues. We believe we have at the Hôpital des Enfants Malades in Paris one of the richest sources of experience in this field; the investigation is being carried out by a team of paediatricians, ophthalmologists, neurosurgeons, pathologists, bacteriologists, and chemists. In this article our preliminary work is being reported for the first time.

#### Importance of Early Diagnosis

We would at once emphasize that we make every effort to detect tuberculous meningitis in children at an early stage in order to be able to treat it in good time. Formerly no great haste was shown in obtaining the depressing confirmation of the disease in cases where meningitis was suspected and there was a risk that a lumbar puncture might even bring it on or be accused of so doing. It is known that tuberculous meningitis often becomes apparent in children at an early stage of the infection: out of 51 cases in our first series in which we were able to observe the onset of allergy 42 developed tuberculous meningitis within six months. The symptoms which should strike one at this stage are headache, vomiting (though this may be only occasional), sudden anorexia, fever, which is always present, and emaciation—but this last to a lesser degree only. If the tuberculosis is of longer duration, as was the case with 22 of our small patients, it is these same symptoms (with the addition of personality changes and insomnia), and here again not the emaciation, which should first attract the attention.

In acute or subacute miliary tuberculosis, which is often so difficult to detect and which is revealed by radiological examination of the lung, latent tuberculous meningitis is not uncommon. We therefore emphasize the fact that it is essential in such cases to employ lumbar puncture as a systematic routine procedure.

In these circumstances we cannot insist sufficiently on the absolute necessity, at the present time, of employing lumbar puncture in all cases where there is the slightest doubt, and, in some instances, of making repeated punctures. The examination of the fundus oculi, an excellent exploratory method, should also be widely used. Choroidal tubercles and changes in the optic disk are frequently observed. (According to data supplied by our colleagues

Monbrun and Lavat, there were 18% of choroidal changes and 47% of disk changes in the cases of meningitis alone, 75% of choroidal tubercles and 56% of disk changes in the cases of miliary tuberculosis with established meningitis, no disk changes and 50% of chorio-retinal changes in the cases of miliary tuberculosis without meningitis.) The detection of these lesions is useful in determining the tuberculous nature of a neurological disturbance of which the diagnosis is indefinite, and observation of them makes it possible, to a large extent, to determine the effect of the treatment.

The importance of these indications lies in the fact that the immediate prognosis of tuberculous meningitis depends chiefly on early diagnosis, and also, undoubtedly, on the energy and duration of streptomycin treatment. Can the decision whether to employ streptomycin therapy, which carries with it grave risks, be based on direct observation of the bacillus in the cerebrospinal fluid? Our answer is "No." In our own statistics, which include 90 definite cases of tuberculous meningitis, direct examination showed acid-alcohol-resistant bacilli in 41 instances only—that is, in about half the cases. Nor can the line to be followed be based absolutely on negative Pirquet's reactions: in four out of 90 cases Pirquet's reaction was negative, but the intradermal reaction was positive. These facts, which have been a matter of common knowledge for some time, have, up to date, been of purely theoretical interest, but they have now come to be of great practical value. Such findings as these are not sufficient reason for refusing to undertake streptomycin therapy when the clinical conditions demand immediate energetic and prolonged action.

The decision is therefore taken after thorough discussion in which all the diagnostic elements are considered: history, knowledge of a recent contact, mode of onset, evolution, cytochemical abnormalities of the cerebrospinal fluid, and even, where necessary, examination of the ventricular fluid, which we found valuable in two cases in infants.

It is possible to determine the exact nature of the disease, with some delay but with absolute certainty, from the results of cultures of the cerebrospinal fluid on Loewenstein's medium, a test which practically never fails.

#### Prognostic Factors

The Clinique Médicale des Enfants has handled a very large number of patients, who often come from great distances, travelling in uncomfortable conditions, and presenting at very varied stages of the disease. This explains why we finally decided to base our preliminary conclusions on

Details of Cases of Tuberculosis			Last lumbar

NOTE.—As the table was received some time after the text, cases treated since the article was written have been included.

70 cases only, leaving aside those patients who died almost at once and in whom the treatment could not have begun to take effect.

So far as one can at the present time attempt to define the new clinical picture of tuberculous meningitis, there are three possible ways in which the disease may develop: (i) some cases deteriorate whatever action is taken; (ii) others, after an encouraging improvement, seem to become stabilized, but gradually the disease, from being subacute, becomes chronic; (iii) others develop favourably and present every clinical appearance of good—even excellent—health, but we do not yet know whether it is possible to describe them as cured or whether relapses will occur.

In the first group were included the cases which developed fatally within a few days (13 of our first 50 patients), those which did so a little more slowly but without showing the slightest improvement (14), and those which succumbed after a very transitory abatement of symptoms (2). These were nearly all cases whose treatment was started too late. At the beginning of the experiment we gave up all idea of instituting streptomycin treatment in patients whose condition seemed to us beyond hope. Of all the unfavourable signs there is only one, in our opinion, which has an absolute value, and that is coma, by which we mean complete abolition of consciousness, absolute insensitivity to the strongest stimuli. This is the only condition in which we consider all hope to be lost. One cannot be so completely pessimistic when confronted by somnolence or torpor, even when this is marked, if one manages to lift the child out of it, even temporarily, and to drag a few coherent answers from him. One must also be on one's guard, in estimating disturbances of consciousness on the child's admittance to hospital, against the transitory aggravation due to being moved and to travelling.

**Early Essays in Treatment**

While we were still clarifying these elements in the prognosis we instituted, at an early stage of our investigation, a method of treatment of which the general principles were: (i) employment of large doses of the order of 100,000 to 200,000 units per kilogram of body weight per day; (2) administration of the drug by both the intraspinal and the systemic route; (3) prolonged treatment, with the highest doses compatible with tolerance for as long as possible.

This method of large doses administered both systemically and locally over a prolonged period was instituted at a time when we had only very vague data on the dosage and toxicity of streptomycin. With experience we found it to be dangerous, as it was the cause of severe—sometimes extremely severe—toxic disturbances. In future the method can only be accepted with reserve. Certain conclusions can be drawn from these results, and above all they provide a profitable lesson for those who may have to handle streptomycin for the first time.

When tuberculous meningitis is treated in this way an embarrassing situation arises out of the concurrence of symptoms and signs caused on the one hand by the disease and on the other by the drug.

The problem now becomes an extremely difficult one to solve, as streptomycin itself, introduced in this way in massive doses, creates an experimental disease that must be recognized in order to avoid therapeutic errors the consequences of which may be fatal to the patients. The disease thus created comprises (a) general toxic disturbances, (b) cutaneous reactions, and (c) meningeal reactions.

(a) The general toxic disturbances completely upset the temperature and weight charts, so that if treatment with large doses (more than 50,000 units per kg. per day) is carried out

no reliance can be placed on either fever or weight as a guide. Streptomycin produces very varied temperature curves: sometimes large waves, or, more especially, wide daily oscillations of the order of 1-2°; sometimes only moderate fever; but the temperature is never normal. Under the same therapeutic conditions the patient does not gain weight: he may lose weight at an extraordinary rate (10 kg. in about a fortnight). Still under the same therapeutic conditions, it is impossible to use the state of consciousness as a basis for estimating the progress of the meningitis. The somnolence and clouding of the mind may be caused by the toxic effects of the drug. If one interprets the fever, emaciation, and somnolence as indications for continuing the treatment, convulsions may well ensue, and these often end fatally or, at best, give rise to that well-known complication of streptomycin therapy, deafness, which has occurred in 15 of our cases, and the onset of which is particularly difficult to detect in the presence of such serious disturbances of consciousness. We should add toxic vomiting to this picture, a symptom which may occur even without intraspinal treatment. We would also mention, as symptoms of less frequent occurrence whose mechanism is still unexplained, tetany (in two cases), hyperazotaemia, and sometimes slight albuminuria.

(b) The cutaneous reactions, in spite of the fact that they may be chronologically independent of the general toxic manifestations, often give some warning: there may be transient erythema resembling that of scarlet fever, measles, or rubella; this is usually accompanied by fever and is in itself a painful complication.

(c) The meningeal reactions are characterized by stiff neck, sharp pain at each fresh injection of the drug, and special symptoms of sudden onset, i.e., severe convulsions with opisthotonos.

We must also mention a point which in our opinion is very important: the fact that repeated large doses of streptomycin introduced into the meninges always produce a violent histological reaction (wide daily variations in the lymphocyte count of the order of 50 to 400 and even 800 cells per c.mm.).

If one adds to the intoxication and meningeal reactions the sufferings caused by local injections whose high concentration makes them irritant and liable to produce abscesses and scars, one finds that practically every case presents a pitiful picture. If, unaware as we were at the beginning of our researches of the general toxicity of streptomycin, one perseveres in the belief that these symptoms constitute a development of the meningitis one is heading straight for disaster. In practice it is essential sooner or later (within from one to three weeks) to cease treatment, possibly for some time if the patient is threatened with deafness. Cessation of treatment is accompanied by improvement or, to be more correct, a veritable resurrection: the temperature falls with surprising rapidity, the weight increases as quickly as it decreased, and the disturbance of consciousness disappears.

If there is too much delay in resuming treatment a probably fatal relapse ensues sometimes after an interval as short as a week, sometimes after the patient has been normal for as long as 85 days. This may happen with devastating rapidity.

It is impossible, therefore, to adopt such a method; that is the first point to be learnt from this therapeutic trial. It is a great strain for the patient, and causes numerous toxic manifestations and sometimes permanent infirmity. It also necessitates, sooner or later, stopping the treatment in circumstances such that one hesitates to resume the administration of the drug. It is essential to recognize all these disadvantages. On the other hand, it should be remembered that such energetic treatment seems to ensure the most rapid improvement in the cellular reaction of the cerebrospinal fluid: we shall see the importance of this later. In order both to exploit the advantages and to avoid

the disadvantages of this method, we finally adopted new therapeutic procedure, which we will now describe its principles and applications.

### Treatment in Present Use

The treatment which we are now using against tuberculous meningitis comprises two distinct phases: the *phase of attack*, followed by the *phase of maintenance*.

The phase of attack consists of large doses: 100,000 units per kilogram per day by the parenteral route and at the same time two intraspinal injections per day of 50,000 to 100,000 units. This treatment is continued for about a week, with some variations to suit individual reactions. In the second phase, treatment is maintained at doses below 50,000 units per kilogram per day by means of parenteral injections alone, no intraspinal injections being given as a rule.

Carried out in this way the phase of attack takes place without any serious disturbances. It may, on occasion, be modified if meningeal intolerance makes this necessary; this would involve giving the intraspinal injections at longer intervals or even stopping them altogether.

The dosage to adopt in the maintenance phase of treatment is a difficult question to settle. Its level may be lowered if there are manifestations of intolerance and particularly if signs of intoxication appear (the much rarer cases of deafness may be encountered even with small continuous doses). What is more difficult still is to assess the progress of the meningitis. It very often happens that the patient appears at this stage to be in excellent condition. What points reveal the state of his meninges? For our part, setting aside the information derived from the comparison of the x-ray plates in the case of associated military tuberculosis of the lungs, we note, among the clinical elements, the development of the pyrexia: any rise in temperature or any wave modifying a curve which has normally been following a progressively downward trend should arouse attention once the possibility of drug fever has been eliminated.

We attach the greatest importance, however, to the essential supplementary examinations—i.e., those of the fundus oculi and the cerebrospinal fluid.

For the observation of a case of meningitis the collaboration of the ophthalmologist is indispensable, as the examination of the fundus oculi is one of the most delicate methods by which it is possible to keep a watch on the progress of the meningitis: the choroidal tubercles, under the influence of the treatment, lose their original aspect and gradually heal or disappear, leaving residual pigmentation. At the same time it often happens that the specialist detects the appearance of fresh tubercles well before the clinician has noticed anything abnormal.

The second indispensable method of investigation is the examination of the cerebrospinal fluid. It required a whole series of accidental circumstances, comparisons of estimations, and discussions before we accorded to the lymphocyte count the importance which it now seems to us to merit. If one takes the trouble to work out the significance of the changes in the lymphocyte count incidental to local treatment, and to study the general trend of the count from a curve plotted from estimations at suitable intervals (about every eight days), one cannot fail to be struck by the importance of the evidence afforded by this means. Thus, in favourable cases it is possible to obtain a count which remains normal or subnormal; in 16 of the cases at present under observation the number of cells per cubic millimetre is always below 10, and generally of the order of 4 or less. On cessation of treatment a sudden rise in the number of lymphocytes may be observed; this appears to precede

clinical recurrence of the infection. If the dosage is diminished a sudden or progressive increase in the number of leucocytes may be noticed. To obtain this return of the cerebrospinal fluid to normal, which we consider dispensable, the minimum dosage varies from one patient to another; in certain cases the minimum effective dose is very close to or even exceeds the toxic dose. This is the virtuality to be dreaded most in practice, and though the situation may not be conclusive it is too soon to be certain at this point.

These are the broad outlines of the treatment which is at present being tried out at the Clinique Médicale des Enfants. The immediate results of the method are good. At the present moment 46 children who have been undergoing treatment for from 2 to 10 months are behaving like normal beings. The tuberculous meningitis ward is like a playroom, where the liveliness provides a constantly changing scene.

The problem arises, or will arise sooner or later, of when to stop the treatment, and this is the most difficult question of all. In every country doctors are asking themselves, when and on what indications can one stop the treatment? For our own part, forewarned by our early mistakes of the ravidity of premature cessation of treatment followed by fatal relapses, we have not yet dared to make the decision. We are treating the children continuously, as diabetics are treated with insulin. Here, to be honest, we come up against an unfavourable factor in the occurrence of streptomycin resistance in the tubercle bacilli, but we have not arrived at any definite conclusions on this still very obscure problem; at the same time there is a favourable factor in the tendency shown by the lesions to heal by degrees as the duration of the tuberculosis increases. We have now decided not to cease treatment until we have the support of a large number of reassuring signs: absence of all clinical meningeal symptoms, an ascending weight curve, complete apyrexia, normal sedimentation rate, and a spinal lymphocyte count below 10 per c.mm. at repeated examinations. We would add to this, absence of tubercle bacilli in culture and, if possible, a normal quantity of cerebrospinal albumin. This last point is justified by an extremely important observation concerning the evolution of certain cases of meningitis treated by streptomycin.

#### Symptoms after Apparent Cure

A fourth group of patients develops in a very peculiar manner, and a knowledge of the facts involved constitutes an indirect advance in the streptomycin therapy of tuberculosis. Though apparently cured of meningitis in so far as they no longer present any clinical syndrome of the infection, are practically free from fever, and there is no longer any serious cellular reaction in their cerebrospinal fluid, these patients do not recover their liveliness like the others, and do not regain weight. Sometimes their neurological examination is not completely negative (there may be cutaneous hyperaesthesia, Babinski's sign, or slight tremor). In this case very careful attention must be given to the examination of the eye and of the cerebrospinal albumin. In these patients the possibility of a mechanical lesion, particularly the setting up of hydrocephalus secondary to meningeal adhesions, should be considered. This is where the neurosurgeon is called in to deal with the new situation; we are not yet certain whether this is the result of tuberculous meningitis or the consequence of a cerebral tubercle against which streptomycin does not seem so far to be as completely effective as against meningitis. The decision to operate was taken in 6 cases. In 5 of these the findings were widespread leptomeningitis or pachymeningitis of the cisterna pontis; in the sixth case there was a large

meningeal tubercle round the chiasma. In two of these cases the results were remarkable, one patient, who was comatose and blind at the time of operation, being one of those who are now giving us the greatest hope. In the new treatment of tuberculous meningitis the neurosurgeon is associated with the physician, as the chest surgeon is associated with the phthisiologist in certain cases of chronic pulmonary tuberculosis.

## THE TROPICAL LICHEN PLANUS SYNDROME

BY

W. WILLIAMS, M.B., Ch.B., LL.B.  
Major, N.Z.M.C.

An unusual disease with striking cutaneous manifestations has been observed in Australian, American, and New Zealand troops serving in widely scattered areas of the Pacific. Because of its geographical distribution, and from some clinical and histological resemblances, it has become commonly known as tropical lichen planus. The condition was briefly referred to by Myers (1944) in the course of a review of skin diseases affecting Australian troops in New Guinea. A detailed account of the findings in some American cases has been given by Bagby (1945).

The aetiology is not definitely established, but there is substantial evidence that the disease has some relation to the use of mepacrine as a malaria suppressive. The public revelation that an identical syndrome has been observed for some time in military forces using mepacrine suppression in Europe and the Middle East substantially confirms this belief (*Lancet*, 1945, 2, 711).

In his account Bagby mentions that the total number of cases in American troops would be impossible to estimate. A reasonable assessment of the incidence, as well as some conclusions from the geographical distribution, can be made from an analysis of the figures for a New Zealand force which operated in the Pacific Zone. This was a relatively small force of some 18,000 men, and it maintained independent medical services. Divisional troops comprised about 12,000 men, and all evacuations from this group came ultimately to a single base hospital, where all skin cases were seen by me. Most of the men in the force had served for periods of six months to two years in Fiji prior to November, 1942. Individual battalions had been stationed also in Tonga and Norfolk Islands. In November, 1942, the force proceeded to New Caledonia. Although some of these islands are quite tropical in climate, none of them is malarious, and therefore no mepacrine suppression was employed. No case of tropical lichen planus, or any condition resembling it, was seen at that time, though the usual tropical dermatoses were prevalent.

In August and September, 1943, the combatant part of the force moved to Guadalcanal, one of the Solomon Islands, some units spending a few weeks on the New Hebrides en route. In the following 12 months they were divided into two groups, which operated independently on various islands in the Solomon region. All these islands are highly malarious, and suppressive mepacrine was started when troops left New Caledonia, being maintained continuously until their return. The rate of administration was 0.1 g. of mepacrine daily for six days in each week.

The first case of tropical lichen planus in this force was evacuated to the base hospital in early December, 1943, and five further cases were received in the following five months. This suggests, at first consideration, a steady trickle of cases, but examination of the histories shows that

of the original symptoms were reported to be negative. Although positive serological findings develop relatively late in pinta it was felt that this diagnosis need no longer be entertained. The improvement in one case following neosarsphenamine was presumably a non-specific effect.

The world-wide distribution of this disorder, its involvement of different racial types, its independence of climate, and its invariable association with the use of mepacrine seem to leave no doubt of that drug's causative role. It also raises the question whether less typical cases may have escaped detection. Out of a profusion of ordinary tropical dermatoses only one other patient seen at the same time as the above group warrants brief description:

Sapper E., when admitted, displayed infiltrated erythematous plaques on the dorsum of both feet, on the extensor surface of his arms, on the back of the hands, ears, face, front and back of the neck, and a few in the axillae. He showed also some patchy loss of scalp hair. He had been taking mepacrine for eight months. The lesions had appeared ten weeks after he started taking the drug, and had advanced slowly thereafter. He had no symptoms. Shortly after his admission, at which time his case was tentatively diagnosed as subacute lupus erythematosus, a peculiar gross patchy hyperkeratosis of his palms appeared, with similar but smaller lesions on the feet. It was identical with that displayed in the typical tropical lichen planus cases. He had no constitutional symptoms. His lesions gradually improved over the next two months, and he was then lost sight of.

Review of the history of Case 3 reveals a considerable resemblance to disseminated lupus erythematosus. Suggestive of this disease were the onset following unusual exposure to sunshine at a picnic—he was an orderly-room clerk and mostly kept indoors—the period of diarrhoea associated with an exacerbation of his rash several weeks after he had stopped taking mepacrine, and the persistently raised sedimentation rate. Against this, and supporting its classification as tropical lichen planus, were the relation to mepacrine, the complete absence of lesions of the face, and the extensive and severe involvement of the palmar and plantar regions.

Biopsy of a fresh macular lesion of the trunk in this case showed a non-specific histology resembling acute solar dermatitis. A hypertrophied scaly papule from the wrist appeared like typical lichen planus in most of its details. It showed hyperkeratosis, increase of the granular layer, acanthosis, liquefaction degeneration of the basal layer, and a diffuse infiltration of the upper cutis by lymphocytes and plasma cells merging with the basal cell layer. In the deeper part of the corium this infiltration was associated with vessels and hair follicles, and there were also some oedema and proliferation of the endothelium of the smaller vessels.

### Summary

In a group of troops serving in scattered tropical areas, both malarious and non-malarious, tropical lichen planus was noted only in those who had taken mepacrine for malaria suppression. The incidence was approximately 1 per 2,000 troops. The initial symptoms appeared when mepacrine had been used for between two and three months. Some of the residual lesions seemed to be permanent. Some resemblance to disseminated lupus erythematosus is noted.

I wish to thank Brigadier J. M. Twigg, D.D.M.S., N.Z.E.F.I.P., for permission to publish this material, and Colonel E. G. Sayers, C.O., 4 N.Z. General Hospital, for his interest.

## POLIOMYELITIS: A SECOND ATTACK

BY

MARY W. ALVES, M.B., Ch.B.

Resident Medical Officer, Hill House Hospital, Swansea

AND

IDWAL PUGH, M.B., Ch.B., D.P.H.

Deputy Medical Officer of Health, Swansea

It is generally believed that second attacks of poliomyelitis are very uncommon, and this seems to be borne out by the small number of such instances reported in the literature. Quigley (1934) collected 12 cases, while Bridge *et al.* (1946) reported 6 among approximately 1,100 cases of poliomyelitis in and around Buffalo during the summer of 1944. In all some 37 cases have been reported in various American publications.

We feel, therefore, that it would be of interest to record the following case of a second attack which came to our notice recently. This was one of the 21 cases admitted to hospital in the Swansea area.

### Clinical Summary

*First Attack.*—A girl aged 3½ was admitted to Hill House Isolation Hospital on Aug. 28, 1938, at the height of a poliomyelitis epidemic. The child had been generally out of sorts and listless for a few days, later becoming febrile, with occasional twitching of face and body. There was no history of obvious contact with infection, but her father worked in close association with a man whose child had been admitted to the same hospital on Aug. 19 suffering from poliomyelitis. On admission the child was pyrexial—temperature 102° F. (38.9° C.)—and showed left-sided facial paralysis and weakness of the abdominal muscles. C.S.F. findings were: colourless slightly granular fluid; 39 cells per c.mm. (all lymphocytes); globulin, faint trace; protein, 30 mg. per 100 ml.; glucose, 74 mg. per 100 ml.; chlorides, 702 mg. per 100 ml.; Lange curve, 0012210000. A facial hook was fitted and the child kept in bed for five weeks. She was discharged a week later with the hook still *in situ*. Subsequently she was seen at regular intervals by an orthopaedic specialist, and at the end of six months the facial muscles showed complete recovery of power and the facial hook was discontinued.

*Second Attack.*—During the current epidemic of poliomyelitis the child, now aged 12, was admitted to Hill House Hospital on Oct. 9, 1947, with a definite attack of the disease. She had had a cold a week previously, followed later by aches and pains "like flu." On the day of admission she became feverish, developed a stiff neck, and had some difficulty in moving her right leg. Again there was no definite history of contact with infection, but a month previously two young children living opposite the patient had been admitted to hospital with poliomyelitis, and the parents of the two families had had frequent contact. On admission the temperature was 100.4° F. (38° C.); there was stiffness of the neck and spine, and a sluggish knee-jerk on the right side. Next day there was paresis of the right gluteus medius and quadriceps with loss of the knee-jerk on the same side and weakness of abdominals. C.S.F. findings were: clear fluid; 89 cells per c.mm. (90% lymphocytes); globulin, trace; protein, 100 mg. per 100 ml.; glucose, 80 mg. per 100 ml.; chlorides, 731 mg. per 100 ml.; Lange curve, ‡12110000.

It will be noted that the following factors were common to both attacks: (1) A fairly typical history in the presence of an epidemic; (2) muscle paralysis and weakness; (3) changes in the C.S.F.—namely, increased cell count and raised protein content—which are consistent with a diagnosis of poliomyelitis. These, we feel, serve to demonstrate the true nature of the illness in both instances.

### Discussion

The occurrence of a clinically recognizable second attack of poliomyelitis, in the ratio of one such case to a total of

only 21 cases, naturally raises a suspicion that immunity acquired after an attack of the disease may not be as complete and lasting as one is generally led to believe. This is the more significant in the light of modern teaching that latent and mild non-paralytic infections are exceedingly numerous during epidemic periods, and that the development of paralysis is an uncommon and unfortunate complication in a minority of cases. Mild atypical cases are unfortunately often missed; at best diagnosis can be confirmed only by expensive and impracticable animal-inoculation tests. In such circumstances it is very likely that atypical second attacks frequently go undetected. In an attempt to ascertain the degree and effectiveness of immunity following an attack of poliomyelitis, Bridge *et al.* (1946) investigated during an epidemic the incidence of illnesses regarded as mild poliomyelitic infections among 168 persons who had had the disease previously. There was definite evidence that 77 of the 168 had been further exposed, and 17% of those exposed revealed symptoms, such as fever, vomiting, muscle spasm, and transient weakness, suggestive of a mild form of the disease.

Whereas little is known of the antigenic structure of the viruses, there is definite evidence that different strains of the poliomyelitis virus exist. Rhodes (1947) describes the main members of the poliomyelitis group of viruses to be the monkey-pathogenic or simian strains, the Lansing, K., and M.M., strains, and Theiler's virus. It is possible that these strains are immunologically different and that each strain affords protection only against itself, despite the fact that the clinical syndrome may be the same in each case. Trask *et al.* (1937a and b) showed that strains isolated from various outbreaks in 1930 and 1931 were immunologically different, while Burnet and Macnamara (1929, 1931) found that monkeys which survived infection with one strain succumbed later to a different strain. Similarly, in 1937 Flexner showed that it was possible for monkeys to suffer two or even three attacks of poliomyelitis—an observation which had also been noted as early as 1913 by Kling and Levaditi.

Poliomyelitis occurs principally in infancy and childhood. Adults are not commonly attacked, presumably because of acquired immunity following latent or subclinical attacks. Nevertheless during the last war the incidence of poliomyelitis was much higher in troops stationed in the Middle East and India than in those in this country, one of the possible explanations being that the former were exposed to a strain against which they had no previous immunity (McAlpine, 1945). It is obvious, therefore, that we should be cautious about accepting the statement that an attack of poliomyelitis confers lifelong immunity, for the immunological link in our chain of evidence is faulty. It is surely our measures for the prevention and control of the disease will be equally faulty.

We are indebted to Dr. H. R. Tighe, Medical Officer of Health, Wanslea, for his interest, advice, and permission to publish this article, and to Dr. A. F. Stadden for his reports on the C.S.F. findings.

## THE TETRALOGY OF FALLOT AND ITS SURGICAL TREATMENT

BY

GORDON MURRAY, M.B., F.R.C.S.Eng.  
F.R.C.S.Can.

Toronto, Canada

The congenital heart lesion known by the popular name of "blue baby" was first introduced by the Englishman, Peacock, as the "blue maladie." Later on, in 1888, Fallot discussed the syndrome and provided the description which is characteristic of the condition as we know it to-day.

It was of interest to inquire into the incidence of the disease. White has stated that congenital heart disease constitutes between 2 and 3% of all cardiac lesions. The tetralogy of Fallot constitutes about 5% of the cases of congenital heart disease. If, however, a case of congenital heart disease has cyanosis, the probabilities are about 75% that the diagnosis is the tetralogy of Fallot.

The characteristic features of the syndrome described by Fallot are: (1) Stenosis of the pulmonary artery, (2) patent interventricular septum, (3) dextra position of the aorta, (4) hypertrophy of the right ventricle. Obviously there will be many variations from this particular set-up. In some the stenosis is greater than in others and the condition is apt to be associated with other congenital lesions.

Considering the possible causes of these defects occurring during the early development of the heart, Maude Abbott (1936) and Blalock and Taussig (1945) have suggested infectious disease of the mother during the first three months of pregnancy. German measles seems to be the commonest offender in this respect, but other conditions affecting the mother's health during this stage of development, when the cardiac chambers and such are being formed, may play an important part.

#### Signs and Symptoms

The clinical findings in the disease are as follows. (1) Cyanosis of the infant. It is usually present at birth, is continuous, and never disappears. (2) There is a strong systolic murmur that is heard best in the pulmonary area and may be heard fairly widely over the praecordium and sometimes in the interscapular region. (3) Clubbing and marked cyanosis of the fingers and toes. (4) The most characteristic sign, apart from the cyanosis, is the limited tolerance of exercise. The patient has marked dyspnoea on the slightest exertion. The cyanosis increases and the child is able to walk only a short distance, when he becomes exhausted and squats down in a characteristic fashion.

Further investigation adds much to substantiate the diagnosis. To compensate for the lack of aeration of the blood there is a polycythaemia, which may be as high as 10,000,000 red cells per c.mm. or more. The haemoglobin is increased in proportion and may rise from normal up to 185 to 190%, and the volume of packed cells (haematocrit) up to 75%. The oxygen saturation of arterial blood is diminished, and in the worst cases it may be below 30%. In patients with a level such as this the exercise tolerance is greatly reduced. When the oxygen saturation is between 60 and 70% the exercise tolerance is improved, and above this level the clinical sign of cyanosis is not present.

The electrocardiogram shows right-axis deviation. X-ray examination of the heart shows enlargement. The characteristic enlargement is a projection of the left ventricle to the left with double apices, and an enlargement

of the right ventricle, the whole suggesting the shape of a Dutch wooden shoe. There is no pulsation in the area of the pulmonary vessels or conus arteriosus, and there is a defect in the heart shadow here which indicates lack of development of these structures. There is no pulsation in the lung fields, so the condition cannot be confused with Eisenmenger's disease.

Further important information may be obtained by catheterization of the heart as described by Cournand *et al.* (1945) and as used by Bing (1946) in Blalock's clinic. The catheter is passed through one of the superficial veins to reach the right auricle under fluoroscopic control. From the auricle blood for oxygen saturation is taken and the pressure recorded. The catheter is then passed on into the right ventricle, when more blood samples are taken for oxygen saturation and pressures are recorded. The catheter can then usually be passed into the pulmonary artery, and saturation and pressures are again recorded. From this evidence one can determine the presence of an interauricular septal defect, an interventricular septal defect, or pulmonary stenosis. The proportionate amount of flow through the pulmonary circulation can also be determined on this information. The information is useful in making a diagnosis, in forming a decision on whether operation is indicated, and in considering the improvement to be expected from it.

Most of the children with this condition die at birth or soon after. A few live to 6 or 7 years, even to 10 or 12. Very occasionally one will survive to adult life. The patient suitable for surgery is the child who has survived for perhaps a year or more, has limited exercise tolerance, and has the findings already enumerated.

#### Treatment

I think the physicians will agree that there is no specific medical treatment that will alter the course of this disease to any great extent. It is due to the pioneer work of Blalock and Taussig (1945) that fairly effective surgical treatment has been devised. The principle of such treatment is to take a large branch from the aorta and anastomose it with the pulmonary artery so that more blood passes through the pulmonary circulation (Murray, 1940). When successfully carried out with a large branch, the results are very impressive. The patient turns from blue to a satisfactory pink colour.

Naturally the operation is one of considerable magnitude and the dangers are not few. In Blalock's early series the mortality rate was about 25%; but according to a more recent publication he has reduced this to 17%. Such a mortality is not surprising, since the patient is a poor subject to stand operation. Moreover, the adjustment in circulation necessary after operation imposes considerable strain on a poorly developed organ. In some patients the heart is too defective, and the cardiac reserve too small, to withstand the change.

In my series of 60 cases of congenital heart disease operated upon there were 40 of Fallot's tetralogy, 11 of patent ductus arteriosus, and 9 others, with an overall mortality of 11.7% and in the tetralogies 7.5% (see Table).

Disorder	No. of Operations	Deaths
Fallot's tetralogy .. .. .	40	3 (7.5%)
Patent ductus arteriosus .. .. .	11	0
Others:		
Pulmonary stenosis, no patent septum .. .. .	1	
No pulmonary artery .. .. .	1	
Persistent truncus arteriosus .. .. .	2	
Eisenmenger's malformation .. .. .	3	
Single pulmonary artery .. .. .	1	
Roger's malformation .. .. .	1	
Total .. .. .	9	4
Total .. .. .	60	7 (11.7%)

After operation the patients are nursed in an oxygen tent for a few days. If a satisfactory anastomosis has been performed, their recovery is surprisingly smooth and the benefits of improved oxygen saturation are obvious usually within a matter of hours. All my patients have received heparin (Murray, 1940) post-operatively to aid in keeping the anastomosis patent.

The surgical treatment of many cases of the tetralogy of Fallot is very satisfactory, bringing relief of symptoms, improvement in colour, and greatly increased vigour.

I wish to thank Dr. Edmund Delorme, Dr. Joseph Janes, Dr. David Bohnen, and Mr. Newell Thomas for their assistance. Dr. Stephen Evelyn's excellent efforts in giving the anaesthetics are gratefully acknowledged. The Trustees of the Toronto General Hospital very kindly provided space for these patients. Otherwise this work was carried on with private funds and without other assistance, except for limited facilities provided by the Banting Institute.

## COMPLETE HEART BLOCK IN YOUNG PEOPLE

BY

J. R. H. TOWERS, M.D., F.R.C.P.

Honorary Physician, the General Infirmary, Leeds

AND

CONRAD BRÉMER, M.D., M.R.C.P.

Medical Registrar, the General Infirmary, Leeds

Persistent complete auriculo-ventricular heart block is rarely seen in young people, and when it does occur it is almost always congenital. Cardiac irregularities, with varying degrees of defective conduction between auricles and ventricles, are not uncommon during the course of diphtheria, acute rheumatism, and occasionally other infections. If complete heart block develops, however, the usual outcome is either recovery, with restoration of normal rhythm, or death.

We describe in this paper three cases of persistent complete auriculo-ventricular block in young people. The first case (O. C.) came under our observation at the age of 12 years; the second (J. M. D.) when she was 17, though the pulse rate was known to have been slow from the age of 7; and the third, a male (D. R.), when he was 18 years old, though his cardiac condition was noted a few weeks after birth.

The following review of the literature shows the comparative rarity of complete auriculo-ventricular heart block even in adults. White (1944) states that 10,000 patients with cardiac signs or symptoms were examined by electrocardiograph at Massachusetts General Hospital: auriculo-ventricular heart block was diagnosed in 641, and of these 79 (0.79% of the total) had complete heart block. He thinks that cases of acquired complete heart block except those due to coronary disease are rare. Yater (1929), described 30 cases of congenital heart block. Jaleski and Morrison (1943) state that up to 1942 only 80 cases of congenital complete heart block had been described; they reported two cases in female patients aged 20 and 21, both living normal lives, in whom the lesion was diagnosed at the age of 6 years and a few months respectively.

Campbell and Suzman (1934) reported 8 cases between the ages of 12 and 33 years. Campbell (1943) had followed up these 8 cases, and of the 7 alive all were in good health and were then between the ages of 22 and 42 years. He states that few of the reported cases of congenital complete heart block have been over the age of 20 years. Leys (1943) described a girl of 23 with complete heart block, dextrocardia, and septal defect. The dextrocardia had been known for some years, but the heart block was first noticed at the age of 20. Peel (1943) reported a similar case in a woman still in good health at the age of 46. The lesion was diagnosed at the age of 38, though at 5 her heart was known to be defective.

Most authors agree on the even greater rarity of persistent post-diphtheritic complete heart block. Jones and White (1928) investigated 100 cases who had suffered from diphtheria at least five years before. In this series the electrocardiograms did not show one example of complete heart block. Fishberg (1940) states that he has seen only one patient surviving the appearance of complete heart block in diphtheria. He refers to 19 cases described by Stechner in 1928, all of which were fatal.

Leys (1945), however, reported a case of complete dissociation of auricle and ventricle in a married woman aged 25 who had had severe diphtheria with palatal and ocular palsies at the age of 10. The available evidence suggested that the lesion was diphtheritic in origin, but proof of a normal heart before the infection was not available. Cookson (1945) investigated 83 cases of diphtheria and stated that the cardiac lesion, however severe, clears up completely if the patient survives; exceptions to this rule are extremely rare.

### Case Reports

**Case 1.**—O. C. attended the children's out-patient department of the Leeds General Infirmary in November, 1929, at the age of 6 on account of her obesity. She was regarded as a case of pituitary dysfunction, but there was no record at that time of the pulse rate or cardiac findings. She was seen again early in March, 1935, suffering from psoriasis, and her notes record a pulse rate of 60 per minute. Almost immediately afterwards (March 13, 1935) she was admitted to the Seacroft Infectious Diseases Hospital, Leeds, with moderately severe faucial diphtheria, which was uncomplicated; the pulse rate on admission varied between 40 and 58 per minute. Three weeks after her discharge on Sept. 7, 1935, when she again attended the Leeds General Infirmary, an electrocardiogram (Fig. 1)

FIG. 1.—Case 1, 1935. Complete heart block; ventricular rate 50 per minute (lead II).

showed complete heart block with ventricular rate of 50 per minute. She lived a normal life with few complaints until June, 1944; she then began to have attacks of "light-headedness," but without actual fainting or loss of consciousness; these have persisted.

FIG. 2.—Case 1. Some increase in transverse cardiac diameter.

She has recently been admitted to St. James's Hospital, Leeds, with the diagnosis of high-grade mental deficiency. Her present weight is 13 stone 12 lb. (87 kg.), and her obesity is of the pituitary type. The heart is slightly enlarged to the left, and a loud blowing systolic bruit can be heard all over the praecordium; B.P. is 120/80; lungs, abdomen, and C.N.S. are normal. Skiagram (Fig. 21 of

chest showed normal lung fields, some increase in the transverse cardiac diameter, but no posterior enlargement. Blood count showed no anaemia or alteration in white-cell count; B.M.R. was +2. Electrocardiograms taken at intervals during 11 years have always shown a complete heart block with a ventricular rate of about 40 per minute (Figs. 3 and 4).

FIG. 3.—Case 1, 1940. Complete heart block; ventricular rate about 40 per minute (lead II).

FIG. 4.—Case 1, 1946 (lead II).

This is considered to be a case of congenital complete heart block with ventricular septal defect complicated by pituitary dysfunction and high-grade mental deficiency. The attacks of dizziness are regarded as of the Stokes-Adams type, and it is noteworthy that these did not appear until she was 21 years old—nine years after the complete heart block had been demonstrated cardiographically; moreover, apart from her mental condition her general health is unimpaired. Particularly interesting is the comparatively high ventricular rate up to the age of 13; it probably accounts for the lesion not being diagnosed in spite of the fact that the patient was attending hospital for various other conditions.

**Case 2.**—J. M. D., a single girl, was first seen on June 6, 1944, at the age of 17 complaining of transient attacks of "light-headedness" without loss of consciousness. She gave a history of diphtheria at the age of 7, for which she was treated at the City Fever Hospital, Bradford. This attack apparently was severe, for she was kept in hospital for a period of 80 days, and her mother was told that the state of the child's heart was endangering her life. Palatal paralysis also occurred. She had a year's convalescence before being allowed to go back to school. For five years she was free of symptoms, but at the age of 12 her present symptoms appeared—i.e., attacks of transient dizziness. These do not seem to cause her much inconvenience, and her general health is good. She is in regular employment as an office clerk.

FIG. 5.—Case 2. Cardiac outline normal.

Physical examination revealed a slim girl who weighed 7 stone 5 lb. (46 kg.). The radial pulse was regular at 42 beats per minute; the heart was normal in size, and on auscultation presented no abnormality except a short basal systolic bruit; the B.P. was 120/75; a skiagram of the chest (Fig. 5) showed no lung lesion, and the cardiac outline was normal in size and shape; the blood count and B.S.R. were normal. An electrocardiogram (Fig. 6) showed complete dissociation between auricles and ventricles, with auricular rate of 80 and ventricular rate of 42 per minute. There is no earlier electrocardiogram, but the general practitioner commented on the slowness of the pulse after the diphtheria. The girl's condition has remained unchanged since 1944; she continues her work as an office clerk and lives a normal life; serial electrocardiograms show no change in the block (Figs. 7 and 8).

This case is one of persistent complete heart block which has certainly been present from the age of 7 to the patient's present age of 21. The lesion was first noted after a severe attack of diphtheria at the age of 7; there is no record of the heart rate before this. The patient's own medical practitioner, however, tells us that before the diphtheria the rate was normal, that this was observed during the course of several small ailments.

and that he compared and contrasted the heart condition on her return from the fever hospital with that before her return. The patient's general health has not been affected although she has had the lesion for 14 years. The attacks of faintness are regarded as those of Stokes-Adams type; they first appeared five

FIG. 6.—Case 2, 1944. Complete heart block; ventricular rate 42 per minute (lead II).

FIG. 7.—Case 2, 1945 (lead II).

FIG. 8.—Case 2, 1946 (lead II).

years after the slow pulse was noted. The severity of the attack of diphtheria, the fact that the cardiac condition was regarded as grave at the time, and the absence of an associated congenital lesion raise the possibility that this is a post-diphtheritic lesion.

**Case 3.**—A young man (D. R.) was first seen on Nov. 22, 1946; he was then 18. His father stated that he had been told shortly after the child's birth that the heart was defective. The patient never suffered from rheumatism, chorea, or diphtheria, and throughout his boyhood he was free of symptoms. He went away to boarding-school and has since been doing heavy work on his father's farm. In February, 1946, he developed a pyrexial illness. The abnormal temperature lasted three days; on the tenth day the patient had an epistaxis followed by a series of faints occurring as often as one every minute. After three days these ceased; he has had none since. However, he

FIG. 9.—Case 3, 1946. Complete heart block; ventricular rate 42 per minute (lead II).

has never completely recovered from this illness and has since been listless, disinclined to do much, and readily fatigued.

Examination revealed the presence of aortic incompetence with a long diastolic murmur down the left border of the sternum and a systolic bruit at the apex. The skiagram showed considerable left ventricular enlargement; the B.P. was 170/60 and in keeping with the valve defect. The electrocardiogram (Fig. 9) showed complete heart block with a ventricular rate of 42 per minute.

This is regarded as a case of congenital aortic incompetence with complete heart block. For 17 years the patient was symptom-free until February, 1946, when he developed fainting attacks of the Stokes-Adams type followed by incipient heart failure.

### Summary

Three cases are recorded of complete heart block, which was first noted at the ages of a few months, 7 years, and 13 years respectively. In all of these there is a history of transient attacks of faintness first manifest at long intervals (17, 10, and 9 years) after the heart block was discovered. In two of the three cases there is an associated congenital heart defect: in one, patent ventricular septum; in the other, aortic incompetence. The third case is regarded as free from a congenital heart lesion.

Two of the three cases are in good general health. The third case has led a normal life (including, up to the age of 17, five years at a boarding-school and two years working on a farm) although the lesion was noted shortly after birth.

Two of the cases (1 and 2) had diphtheria; two of the three cases (1 and 3) are certainly of congenital origin; Case 2 is regarded as diphtheritic in origin.

## TONSILLECTOMY AND ADENOIDECTOMY UNSATISFACTORY RESULTS DUE TO CHRONIC MAXILLARY SINUSITIS

BY

F. M. WALKER, M.B., Ch.B., F.R.F.P.S.  
Ear, Nose, and Throat Surgeon, Ayr County Hospital and  
Ayr C.C.

Ayrshire, 1,132 square miles in extent, partly industrial and partly rural in character, has a pre-school population of approximately 23,000 and a school population of approximately 47,000. In this county since 1936 the local authority has reserved a minimum number of 25 beds for such children as have required operative treatment for affections of the ear, nose, and throat. The number of beds at present so reserved is 34.

In the case of the children who have been dealt with under the treatment scheme in question—children who have been referred by the school medical officers or by private practitioners—the notes about the operations and the follow-up notes were made by the operator himself. The case histories were taken under the supervision of one person—the matron in charge of the hospital.

It became more and more apparent during recent years that a considerable proportion of the cases which were referred for operative treatment of tonsils and adenoids had failed to benefit thereby, even though the operations were technically perfect. With increasing frequency children who had been operated upon months or years previously were referred afresh by school medical officer or family doctor, disgruntled parents declaring that the child's signs and symptoms were much as they had been before operation or that they had become more pronounced. The position was studied, therefore, and it became evident that the unsatisfactory results were due to infection of the maxillary antra.

The following data were derived from the cases of chronic maxillary sinusitis found among the total number of cases referred for tonsillectomy and adenoidectomy in 1946. Of the 1,779 cases operated upon that year—boys and girls in equal proportion—for the removal of tonsils and adenoids, 442 (or 25% of the total) were considered to have sufficient signs or symptoms, or both, to warrant the proof-puncturing of both antra immediately before operation. (The method used was to continue lavage through the antral cannula with normal saline until all traces of pus had disappeared. Swabs were taken at once from the gross pus and sent for culture. In 106 cases no pus was

collected, because in some it passed into the nasopharynx and was swallowed or contaminated, and in others no actual infection was present. Incompleteness of reports in 24 of these 106 cases brings the number to be considered down to 82. In the remaining 336 cases—i.e., in 19% of the 1,779 cases—the material was grossly purulent, mucopurulent, or mucoid. A number of the results of swab examination were lost, however, and some of the case histories were incomplete, so that for these and related reasons 46 cases have to be deducted. The number of cases on which this paper is based is therefore 290, or 16% of the total.

### Signs and Symptoms

In recording the signs or symptoms noticed by parents attention was paid to such matters as headaches, pyrexia of short duration and unknown origin, and repeated "bronchial attacks"—not true attacks of bronchitis—characterized by pyrexia and a hacking spasmodic cough. The following code was used: (1) Interference with breathing, day or night; mouth breathing; snoring. (2) Alteration of voice. (3) Pain in, or discharge from, ears. (4) Cervical gland enlargement. (5) Sore throat. (6) Mucopurulent nasal discharge. (7) Night terrors and restless sleep. (8) Spasmodic cough. (9) Frequent colds.

In Table I is given the total percentage incidence of each of the nine items which are covered by the code in (a) a random sample, 2,000 in number, of the cases of tonsillectomy and adenoidectomy dealt with over the past seven years; (b) 290 cases in which pus was present in the antra and was washed out at the time of tonsillectomy and adenoidectomy; and (c) 82 cases in which no pus was found, although expected on clinical grounds. In each of the three groups the total percentage incidence of certain infectious diseases is also given.

TABLE I

	Code Number									Infectious Diseases				
	1	2	3	4	5	6	7	8	9	Scarlet Fever	Diphtheria	Measles	Whooping- cough	Pneumonia
Percentage in group (a) ..	69	60	15	30	64	46	6	7	64	12	8	50	20	1
" (b) ..	57	44	19	17	36	48	27	36	59	5	11	60	33	9
" (c) ..	73	46	31	21	46	57	29	39	74	6	14	64	32	6

It is of interest to note that glandular swelling was twice as common in uncomplicated cases as in cases with sinusitis, and that night terrors and spasmodic cough were five times more common in the latter group than in the uncomplicated cases. Certain signs and symptoms—viz., those indicative of sinusitis—noticed by the nurse, the surgeon, and the anaesthetist were also recorded. Thus the nurse, on the morning of the operation, made each child blow his nose into a swab; each case in which there was considerable purulent discharge was recorded as "dirty nose." The surgeon recorded the presence of such signs as nasopharyngeal discharge of purulent or mucopurulent material; pus under, around, or above the inferior turbinates; dermatitis of the nasal vestibule and of the upper lip; and a pinkish tinge of all the structures of the middle ear. The anaesthetist kept in mind the fact that there is a greater tendency for a patient with maxillary sinusitis to cough in the initial stages of anaesthesia with ethyl chloride or gas, oxygen, and trilene, and that when a direct laryngoscope is used for endotracheal intubation the anaesthetist commonly notices a marked general congestion of the larynx and the presence of copious pus.

**Operation Findings.**—These are given in Table II. The condition of the tonsils is classified as follows: (1) Tonsils

"normal": no macroscopic evidence of sepsis on closing the guillotine. (2) Tonsils "septic": some pus extracted on closing the guillotine. (3) Tonsils "very septic": large quantities of pus extracted on closing the guillotine. Of the adenoids, one + sign indicates a normal quantity of tissue, two + signs a mass causing considerable obstruction, and three + signs a very large mass.

TABLE II

Operation Findings	Tonsils Normal	Tonsils Septic	Tonsils Very Septic	No Adenoids	Adenoids +	Adenoids ++	Adenoids +++
Percentage in group (a)	23	50	27	27	18	46	9
" (b)	11	66	23	24	61	14	1
" (c)	3	55	42	8	60	32	—

It will be noted that in group (b)—cases complicated by the presence of sinusitis—the incidence of abnormal tonsils was high (89%) whereas that of abnormal adenoids was low (15%).

**Post-operative Findings.**—The throats, which were examined night and morning during the 48 hours after operation, showed much more purulent material in the complicated cases than in the uncomplicated. There were long streams of purulent discharge flowing down the posterior pharyngeal wall, and the nasal discharge was often profuse also.

**Seasonal Incidence.**—There was no appreciable difference, month by month, in the proportion of the complicated cases in relation to the total number.

**Sex Incidence.**—Boys constituted 54% of the 290 cases, girls 46%.

**Locality.**—The 290 cases with sinusitis came from 56 different towns or villages. The county medical officer of health, whose comment was invited, replied that he could find no ruling factor.

**Social Position.**—This appears to have no bearing on the incidence of the condition, for the percentage of complicated cases was 22% of a smaller series of tonsil and adenoid operations done in nursing-homes during the same year.

**Age Incidence.**—This is shown in Table III. So few cases fell in the last two age groups that the percentage figures shown are of little value.

TABLE III

Age in Years	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Per cent of total (1,779)	12	19	23	16	22	25	17	13	16	18	25	11	14	14	25

**Bacteriological Findings.**—One single type of organism was present in 35% of the cultures, while 2, 3, or 4 different organisms were present in the others. The most common single type of organism was *Streptococcus viridans*, which was found in 11% of the total. *Micrococcus catarrhalis* was present in 49% of all the cultures, *Str. viridans* in 38%, diphtheroids in 25%, *Staphylococcus albus* in 23%, *Staph. aureus* in 17%, haemolytic streptococci in 8%, pneumococci in 6%, *Bacterium coli* in 1%, *Pseudomonas pyocyanea* in 0.7%.

### Results of Treatment

The children were asked to report at follow-up clinics three months after the date of operation. Cure was considered to be complete when all signs and symptoms had disappeared, the opinion being confirmed by radiographic examination in many cases. Of the 290 cases 29 failed to report, 153 were completely cured, and 128 were still unsatisfactory. Of the 82 children in group (c), from whom no pus was obtained on washing out the antra at the time

of tonsillectomy and adenoidectomy although the clinical picture suggested that it was present, 78 attended again, and of these 64 were cured and 14 still showed clinical and radiographic evidence of chronic antral infection. Investigation failed to show that it was easier to eliminate one particular organism or group of organisms than another.

Before 1946 the use of Proetz suction with 0.5% ephedrine in normal saline gave some satisfactory results, but this method was not found suitable for the great majority of these cases because of the large area over which the patients were scattered and the need for repetitions of the treatment. Instillation, after antral wash-out, of "sulfex" and penicillin (10,000 units in 1 ml. of fluid) into different series of cases proved to be no more effective than ordinary antral wash-outs, nor did the use of neutral acriflavine or boric-acid lotion prove to be superior to normal saline.

The unsatisfactory cases reported once weekly for an antral wash-out under general anaesthetic. If the condition was not clear by the time six wash-outs had been given, the children were admitted to hospital for a double antrostomy; this was followed by five days' treatment by chemotherapy and full doses of penicillin. It is too early yet to assess the results of this last method of treatment.

### Comment

Adenoidal enlargement, which in this area at least has been seen much less often in recent years, is certainly not related to sinusitis in children, but diseased tonsils are closely associated with the condition, although there is no indication whether tonsils or sinuses are diseased first. During 1946 about 50% of the cases of sinusitis were cured by one antral wash-out combined with the removal of tonsils and, when present, adenoids. Whether the antral wash-out was necessary is problematical, but during the present year no antral wash-outs are being done at the same time as tonsillectomy and adenoidectomy. This year the cases of clinical chronic sinusitis are being noted, and the parents are being informed that a nasal condition is also present and that they will be asked to bring their children back in three months' time. It is hoped in a year's time to give comparative figures for cases of chronic sinusitis treated by tonsillectomy and adenoidectomy alone.

### Summary

Analysis of the 1,779 cases in Ayrshire operated on for tonsils and adenoids in 1946 has shown that unsatisfactory results following tonsillectomy and adenoidectomy are due, in the great majority of instances, to the presence of chronic maxillary sinusitis, a condition which in children is often associated with night terrors, restless sleep, chronic cough, headache, and pyrexial attacks of short duration. Maxillary sinusitis in children of this particular area does not appear to have any direct connexion with climate, diet, housing conditions, previous infectious diseases, or infection with any particular organism.

I should like to acknowledge the help given to me by the Maïron and the nursing and clerical staffs of Seafild Children's Hospital, Ayr, in compiling the figures recorded above.

The Registrar-General announces that from Monday, Dec. 15, a new and short form of birth certificate, costing sixpence, will be available showing only the name and surname, sex, date of birth and (where possible) place of birth. There will be no particulars of parentage or adoption. In the case of births registered in England or Wales application can be made to the Superintendent Registrar of the district in which the birth occurred or to the General Register Office, Somerset House, London, W.C.2. A short certificate can also be obtained from the local Registrar at the time of registration of the birth. Where births have been registered abroad and entered in Army, Air Force, Consular, or Marine records deposited with the Registrar-General, certificates can be obtained only from the General Register Office, Somerset House. This applies also to certificates relating to adopted children.

## Medical Memoranda

### "Spontaneous Rupture" of Spleen Associated with Infective Mononucleosis

Although it is well known that spleens that are enlarged in fevers such as malaria are very easily injured, the following case of so-called "spontaneous rupture" in infective mononucleosis seems rare enough to be worth recording.

#### CASE HISTORY

An airman aged 25 was admitted to hospital early one morning with the "provisional diagnosis" of a perforated peptic ulcer. He had been taken off a train in which he had suddenly become prostrated with severe abdominal pain. His previous movements are of interest: he had travelled in overcrowded trains for several hours, and on the last lap of the journey he had been sitting doubled up on a kitbag in one of the corridors. An hour or two before the onset of the acute symptoms he had experienced a mild pain in the left side which gradually passed off.

On admission he was found to be very restless and in too much pain to answer questions coherently. He was considerably shocked, and there was a board-like rigidity of the abdomen. The clinical picture was strongly suggestive of blood in the peritoneum, but it was difficult to reconcile this with the history given. The extreme restlessness was all against the presence of a perforation. The temperature was 100° F. (37.8° C.).

Laparotomy was performed through a right upper paramedian incision, and the peritoneum was found to contain a large quantity of dark blood. The spleen was twice the normal size, and there was a subcapsular haematoma, the capsule having ruptured near the lower pole of the organ. Splenectomy was carried out without difficulty and the abdomen closed.

Post-operatively, plasma and glucose-saline infusions helped to combat the shock, but later in the day the temperature rose to 102° F. (38.9° C.). A blood examination showed: R.B.C., 4,380,000 per c.mm.; Hb, 84%; colour index, 1; leucocytes, 29,600 per c.mm. (polymorphs, 44%; lymphocytes, 45%; monocytes, 11%); platelets, 512,000 per c.mm. The red cells were normal in all respects, but many of the lymphocytes were irregular in size. The result of a Paul-Bunnell test the following day was positive in serum dilutions 1 in 3 to 1 in 12, and negative from 1 in 24 upwards; this titre increased, and one week later there was a positive result from 1 in 3 to 1 in 24, with negative findings from 1 in 48 upwards.

During the first post-operative week the temperature "swung" between 102° and 100° F., and there were a few palpable lymph nodes in the axillae and left posterior triangle of the neck. The results of absorption tests against both guinea-pig kidney and ox cells were negative in dilutions from 1 in 3 upwards, suggesting a serum-sickness reaction.

Although the absorption tests did not give confirmatory evidence of glandular fever, the blood picture, then and subsequently, was characteristic of that disease. A later count showed: R.B.C., 5,100,000 per c.mm.; Hb, 100%; colour index, 1; leucocytes, 11,200 per c.mm. (polymorphs, 40%; lymphocytes, 57%; monocytes, 1%; basophils, 1%; eosinophils, 1%). Sections of the removed spleen revealed the normal splenic architecture and a gross infiltration of the parenchyma with lymphocytes and monocytes, all intermediate types being seen.

In the absence of a sufficient titre in the Paul-Bunnell reactions, and the fact that the absorption was not the type usually seen in infective mononucleosis, it is difficult to be certain of the diagnosis of infective mononucleosis. On the other hand the blood picture and splenic histology were characteristic of this disease. The patient had not been abroad, and at no time was there any evidence of malarial parasites.

Unfortunately this patient developed a left-sided pleural effusion, which doubled his recovery time but did not affect his ultimate full recovery and return to duty.

#### COMMENT

The spontaneous rupturing of a spleen in glandular fever must be a comparative rarity, but this case proves it to be an actual possibility, the trauma having been no more than "subminimal." It would appear wise, therefore, to bear this in mind when treating known or suspected cases of this disorder and when diagnosing an unexplained abdominal crisis.

My thanks are due to Dr. J. H. Gubbin, medical superintendent, E.M.S. Hospital, Salisbury, for permission to publish this case.

Graded Surgeon, E.M.S.

## Reviews

### PRELUDE TO MEDICINE

*Medicine. Volume I. The Patient and his Disease.* By A. E. Clark-Kennedy, M.D., F.R.C.P. Complete in two volumes. (Pp. 383. 20s.) Edinburgh: E. and S. Livingstone. 1947.

Dr. Clark-Kennedy has had an unusual career, for he is at the same time a fellow of a Cambridge college, a physician, and the dean of a London medical school. It is, therefore, not surprising that, with his intimate experience of different aspects of the teaching and practice of medicine, he has written an unusual book. There is reason to believe that he wrote much of it during the war, when the hours of waiting provided leisure to think, and the threat of imminent destruction prompted thought on the meaning of existence and the role of the physician in the prevention of sickness and premature death. Nevertheless the spirit of the university inspires him rather than that of the medical school, the university in which men of different faculties and disciplines meet in a single community and have the opportunity to share and test each other's ideas. The author's aim is to provide a philosophical foundation on which a knowledge of medicine can be built as experience accumulates. In this first volume he considers body and mind, symptoms and signs, heredity and environment, reactions of the body and the mind, and the nature of disease. The author admits that this "may seem a strange and unusual prelude to the study of clinical medicine. But the art of medicine is concerned with human bodies made of matter, transforming one form of energy into another. They are partly dominated by mind and individual personality. Everyone does live a finite life in space and time in a mysterious universe. It is natural and logical to start by considering the nature of matter, energy, life and mind, and the relationships which exist between them in so far as matter, energy, life and mind are really comprehensible to the limited capacity of the mind of man. Clinical medicine cannot altogether avoid metaphysics and philosophy."

The adult medical reader will enjoy this delightful book: there has been nothing quite like it since Trotter's writings. The author expresses himself clearly, and again and again excites our imagination by synthesizing information from widely different fields. Many will find it an excellent bedside book, an aid to knitting up the unravelled threads of the day. It is difficult to know how it will affect the beginner. We wonder whether its individualistic flavour will be altogether to the taste of the younger generation. It contains nothing about positive health, social medicine, or demography; in fact, as the subtitle indicates, the author is concerned with the patient and his disease. Though the cash nexus between patient and doctor may be broken, sickness must always remain a problem of the individual as well as of the community. Dr. Clark-Kennedy clearly presents the problem and the solutions which materialist and idealist have given to it.

L. J. WITTS.

### FERTILITY

*The Problem of Fertility.* Proceedings of the Conference on Fertility held under the Auspices of the National Committee on Maternal Health. Edited by Earl T. Engle. (Pp. 254. \$3.75 or 21s.) Princeton: Princeton University Press. London: Geoffrey Cumberlege (Oxford University Press). 1946.

This book consists of 17 papers presented at a conference whose main purpose was the discussion of recent investigations into the processes of reproduction in domestic animals. Only four of the papers are directly about human fertility, yet the book will be of great interest to medical practitioners, for the study of the comparative physiology of reproduction is fascinating in itself, and from it arise many possible suggestions for research and treatment in the human field—a point brought out clearly in the discussions that followed the papers. For example, it has been shown that in sheep and goats the survival power and speed of travel of spermatozoa in the female genital tract are lower when ovulation is stimulated by artificial means than at the time of natural oestrus, which prompts the question whether there is sometimes a similar

explanation for the poor results which attend the use of gonadotrophic hormones in the treatment of the infertile woman. Again, the demonstration that thyroid treatment prevents the normal summer decline in spermatogenesis in rams, and that it raises the fertility of some bulls, is consistent with its reported beneficial effect in some cases of infertility in man.

The subjects discussed include patterns of oestrus cycles; the induction of ovulation and its mechanism and hormonal control in different species; the characteristics of cervical mucus in relation to menstruation and fertility; the viability and metabolism of bovine, human, rabbit, and equine spermatozoa; and artificial insemination in animals. Many of the advances and discoveries made by biologists and veterinary surgeons in recent years do not ordinarily come to the notice of the clinician and the clinical research worker, and the converse also is true; this book is a line of communication between the two groups. As a corrective to those who underrate the knowledge of our forebears A. R. Abarbanel pays a tribute to Dr. W. Tyler Smith, an Englishman who in 1855 described not only the cyclical changes in human cervical mucus but also the function of the cervical plug and the significance of its softening at the optimum time for conception; and J. W. Bartlett reports that artificial insemination was successfully carried out on a mare by an Arab chief as long ago as 1322. This volume is a worthy successor to that of 1945; the subject matter is different but of a high standard, stimulating as well as informative, factual rather than theoretical. It merits the attention of all those interested in human fertility.

T. N. A. JEFFCOATE.

### MANUAL FOR THE TROPICS

*Memoranda on Medical Diseases in Tropical and Sub-Tropical Areas.* Eighth edition. (Pp. 396. Illustrated. 7s. 6d.) London: H.M. Stationery Office. 1946.

This manual will continue to help medical men practising in the Tropics or in the Mediterranean or other sub-tropical countries. As Lieut.-Gen. Sir Alexander Hood notes in a short preface, the memoranda were originally compiled by Sir Andrew Balfour for medical officers serving abroad in the war of 1914-18 and expanded in two subsequent editions by Lieut.-Gen. Sir William MacArthur. For the present edition, which is anonymous, the text has been largely rewritten and brought up to date. As the title implies, the book is not a condensed treatise on tropical medicine but a selection of those points likely to be useful in the diagnosis, treatment, and prevention of some 40 or more diseases—accounts of which are arranged alphabetically—of the Tropics and sub-tropical lands, and it presents a digest of the varied medical experience of tropical conditions and diseases gained by the Army in the recent war.

The information about antimalarial drugs and modern ideas of treatment is well set out, though the reviewer does not consider that quinine should now ever be given intramuscularly. In the section on arthropod pests it would have been useful to have a brief note on "mites," which were so important in the war, and even one on "leeches," but space no doubt has been limited. The book is of convenient size and, unlike the seventh edition, bound in boards. There are 37 plates illustrating diseases and disease vectors, and a number of figures in the text. The use of D.D.T. against insect pests is described in an appendix, and there is a note on zoological nomenclature quoting the more important of the Articles of the International Rules of Zoological Nomenclature.

S. R. CHRISTOPHERS.

### STUDY OF ALCOHOLISM

*Recent Trends in Alcoholism and in Alcohol Consumption.* By E. M. Jellinek, Sc.D. (Pp. 42. \$0.50.) New Haven, Connecticut: Hillhouse Press. 1947.

The author is concerned with the fact that from time to time extravagant conclusions have been attached to observations on alcoholism which relate to highly specific and small units—conclusions which find their way into the news irrespective of whether they are based on superficial judgments or on proper investigation. His statistical study is intended to answer questions which are disturbing the public mind, and he analyses

consumption statistics, the rates of alcoholism in the adult population, the number of first admissions for alcoholic mental disorders to mental hospitals, and other indices of inebriety.

Dr. Jellinek points out that such a question as, "Is drinking on the increase?" lacks precision, since modifications in the consumption of alcoholic beverages may arise if the number of drinkers or individual consumption changes. Comparison of the consumption rates of a head does not disclose the nature of the changes in the drinking habit of a nation or of a group within the nation. The entire increase in the rate of chronic alcoholism in America since 1930 has appeared in urban areas, while the rate in the rural areas has slightly decreased. Dr. Jellinek finds that a large consumption of distilled spirits and a small consumption of beer are together usually an indication that the drinkers are relatively few in number but individually are heavy consumers. He believes that in America approximately 3 drinkers out of every 200 become chronic alcoholics. He refutes the assertion that inebriety among women is increasing at a higher rate than among men, and states that while female inebriety increased during the war it has not increased faster than male inebriety, and the rates in both sexes remain far below those found before Prohibition. He finds no statistical evidence to support the impression that alcoholism has recently been occurring in younger people than formerly, and he considers that the significance of the description of first admissions for alcoholism to mental hospitals is more limited and less definite than the statistical estimates of chronic alcoholism, since they relate to a highly selected portion of the alcoholic population and contain certain artifacts. He also believes that the "trend of death from alcoholism" does little more than reflect the progress of medicine in the treatment of the diseases of chronic alcoholism. The essay is clear and precise and should help to dispel some of the loose thinking which is occasionally apparent in discussions on alcoholism.

W. NORWOOD EAST.

### LIVER DISEASE

*Nouvelles Études Cliniques et Biologiques sur la Pathologie du Foie.* By Étienne Chabrol. (Pp. 184; 24 figures. 250 francs.) Paris: Masson et Cie. 1946.

The writer of this review (and of many unsigned in this *Journal* in the past) has often drawn attention, and does so again, to the isolated and independent point of view expressed in French medical literature in comparison with that found in American, British, and pre-war German writings. Writers in these three countries express their ideas in similar terminology, though in their own tongue, and usually discuss their subject in fundamentally the same way. French writings reveal a quite different outlook, and, except for a few classical and often old papers, the Frenchman seldom refers to any literature except his own. We probably miss much by somewhat neglecting modern French medical writing, but the Frenchman seems to miss more if, as we may assume by his omitting the references, he is unfamiliar with the work being done in other countries.

This volume by the well-known Prof. Chabrol, of Paris, contains a series of essays on different aspects of the clinical pathology of the liver. In some of them he discusses the recent work, essentially French in its origin, on the lipoids of the blood and the esterification of cholesterol in hepatic disease. In a chapter entitled "La Maladie de Hanot Existe-t-Elle?" he discourses on the study of an old French conception. In other sections he considers the premonitory haematurias of cirrhosis, hepatitis "en tache de bougie," the curable anasarca of jaundice, hepatic colic in heart disease, and so on. Such chapters reveal, as we have suggested, an approach quite different from ours to hepatic disease, and a terminology to which we are not accustomed. The whole book is of great interest and value to a student of diseases of the liver, but the ideas expressed require considerable rearrangement if we are to interpret and correlate them with our own.

J. W. MCNEE.

The Minister of Health has accepted further recommendations of the Mental Nurses Subcommittee (Notes No. 9, H.M.S.O., 9d.) and has informed the relevant authorities that the additional expenditure incurred in adopting these recommendations will be met in the usual way by an Exchequer grant.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Lehrbuch der Medizinischen Entomologie.* By Prof. Dr. E. Martini. 3rd. ed. (Pp. 633. Paper covers, Rm.27; stiff covers, Rm.29.) Jena: Gustav Fischer. 1946.

A profusely illustrated textbook of the insects met with in medicine.

*Kurzes Handbuch der Ohrenheilkunde.* By Prof. Dr. Hermann Marx. 2nd ed. (Pp. 888. Paper covers, Rm.46; stiff covers, Rm.48.50.) Jena: Gustav Fischer. 1947.

A textbook of diseases of the ear, nose, and throat.

*Manual of Physical Diagnosis.* By E. B. Freilich, M.D., F.A.C.P., and G. C. Coe, M.D. 3rd. ed. (Pp. 351. 55 or 27s. 6d.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

The clinical examination of patients; an account intended particularly for students.

*Dark Legend: A Study in Murder.* By F. Wertham. (Pp. 116s.) London: Victor Gollancz, Ltd. 1947.

A study of a boy who killed his mother.

*Personality and Problems of Adjustment.* By Kimball Young. (Pp. 868. 35s.) London: Kegan Paul, Trench, Trubner and Co. 1947.

An account of the development of the individual from childhood onwards in society.

*Your Health in War and Peace.* By J. Halliwell. (Pp. 60. 2s. 6d.) Essays in popular journalism on various aspects of health.

*Emotional Problems of Living.* By O. S. English, M.D., and G. H. J. Pearson, M.D. (Pp. 438. 16s.) London: George and Unwin. 1947.

A psycho-analytic account of mental development; intended for the intelligent reader untrained in psycho-analysis.

*Old Age: Its Compensations and Rewards.* By A. L. Visch M.D. (Pp. 200. 12s. 6d.) London: George Allen and Unwin. 1947.

Discusses the problems of ageing and the aged; for the layman.

*Genetics in Relation to Clinical Medicine.* By F. A. E. M.D., D.Sc., Ph.D., F.R.S., F.R.C.P.Ed. (Pp. 111. Edinburgh and London: Oliver and Boyd. 1947.

Intended to instruct medical students and postgraduates taking D.P.H. in the role played by genetic factors in the causation of disease.

*Peace of Mind.* By J. L. Liebman. (Pp. 203. 8s. 6d.) London: William Heinemann. 1946.

A discussion for the layman of problems in human conduct.

*Chiropody To-day.* By E. S. and F. Boothway, M.A.C.Ch. L.Ch. 2nd ed. (Pp. 141. 7s. 6d.) London: Hutchinson. 1946.

An introduction to the practice of chiropody.

*The Chess Pilot.* By J. Mieses. (Pp. 64. 3s. 6d.) London: Williams and Norgate. 1947.

An introductory account of the openings in chess.

*Stammering.* By K. Emil-Behnke. (Pp. 97. 6s.) London: Williams and Norgate. 1947.

An account of stammering and its treatment.

*The American Illustrated Medical Dictionary.* By W. Newman Dorland, A.M., M.D., F.A.C.S. 21st ed. (42s. indexed 40s. plain.) Philadelphia and London: W. B. Saunders Company. 1947.

Many new terms from war medicine, pharmacology, and nuclear physics are included in this edition.

*Vade Mecum of Medical Treatment.* By W. Gordon Se M.D., M.R.C.P. 5th ed. (Pp. 407. 10s. 6d.) London: Edward Arnold. 1947.

A summarized account of the treatment of those diseases met with most commonly in general practice.

*Wayfarers in Medicine.* By W. Doolin. (Pp. 284. 21s.) London: William Heinemann. 1947.

Essays on unusual subjects in medical history.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 6 1947

STREPTOMYCIN IN TUBERCULOUS  
MENINGITIS

Streptomycin does two things which penicillin does not: it acts vigorously on almost all Gram-negative bacilli and on the tubercle bacillus. Grave infections such as meningitis or septicaemia due to Gram-negative bacilli are comparatively rare, hence streptomycin as a life-saving agent finds its principal use in tuberculosis. The study of this form of treatment was for some time pursued exclusively in the U.S.A.; some account of the results, as communicated to a conference in London this summer, was given recently in this *Journal*.<sup>1</sup> Among other published accounts is that included in a general report on streptomycin therapy<sup>2</sup> by the National Research Council of the U.S.A., and one by H. C. Hinshaw and his colleagues<sup>3</sup> on the results obtained in 100 cases of various forms of the disease. Apart from clinical work, the careful experimental studies of W. H. Feldman<sup>4</sup> have shown that streptomycin has a remarkable effect on the disease in guinea-pigs, even under the most severe conditions, such as intravenous inoculation with a large dose of bacilli or the deferment of treatment until six weeks after inoculation by the ordinary route. These studies afford a sound basis for attempting the treatment in man and answer a number of questions which naturally arise in this connexion. Feldman showed, for instance, that 10 strains of *Myco. tuberculosis*, of which 2 were bovine, all reacted alike, and brought out the interesting point that tubercle bacilli do not acquire resistance to the drug in guinea-pigs, although this is unfortunately a common occurrence during the treatment of human patients. He also studied the response to different dosage intervals, with somewhat surprising results which have yet to be duplicated in the clinical field.

Clinical experience in the U.S.A. has provisionally defined the indications for streptomycin treatment fairly clearly. In general it is not indicated in chronic forms of the disease or in cases with a good prognosis apart from such treatment. The second proviso is dictated not merely by the need for economy but by the risks involved, which must be balanced against those of the disease itself. R. F. Farrington and his colleagues<sup>5</sup> have found that streptomycin of a high degree of purity has almost all of the toxic effects which it was hoped to be able to attribute to impurities in earlier products. Hence the more acute and severe the infection the clearer the indication for streptomycin, and it was natural that the clinical trials embarked

on at a limited number of centres in Great Britain at the beginning of this year should be restricted to cases of miliary tuberculosis and of tuberculous meningitis. Pending a report on the results obtained here, it is of great interest to bear of further extensive experience in another country, and we publish in the opening pages of this issue an account by R. Debré and his colleagues of the treatment of no fewer than 118 cases of tuberculous meningitis at the Hôpital des Enfants Malades in Paris. Their paper gives only a general survey of this extensive material, but many details of each individual case are tabulated and will provide much information for those more closely interested in this subject.

These authors first emphasize the necessity for early diagnosis, contrasting this with an evident reluctance to take the necessary steps to this end which existed before any effective treatment was available. Actual coma is the only quite hopeless prognostic sign, but the earlier treatment is begun the better, and lumbar puncture to detect "latent" meningitis is indicated in any patient with signs of miliary spread. Emphasis is laid on the value of retinoscopy in diagnosis. The specific results of diagnostic lumbar puncture are disappointing in this series. That tubercle bacilli should have been found in films of only 41 cerebrospinal fluids among 90 definite cases of tuberculous meningitis is out of accord with experience elsewhere. It should be possible to find them in a much higher proportion of cases, if not in all. As these authors remark, it is almost always possible to confirm the presence of tubercle bacilli by cultivation, and the culture then affords equivalent if belated justification for treatment. It is not clear whether in the 13 cases in this series in which the diagnosis apparently rested on clinical grounds alone cultivation of the cerebrospinal fluid was omitted, or failed.

Treatment was first attempted by the administration of comparatively large doses, using both the intramuscular and intrathecal route. The maximum dose mentioned—200,000 units per kilogram of body weight per day—is equivalent to a daily dose of about 10,000,000 units (10 g.) in an adult, and is thus two or three times greater than the maximum dose advocated by American authors. This system of treatment produced an "embarrassing situation" in which the symptoms and signs of a new "experimental disease" had to be distinguished from those of the disease being treated. The manifestations attributed to streptomycin intoxication include fever, rapid loss of weight, somnolence and mental changes, deafness, skin eruptions, and meningeal reactions, including rigidity and even convulsions as well as cerebrospinal-fluid pleocytosis. Deafness, which may be very difficult to detect in unconscious or semi-conscious patients, was produced in 15 cases: this is of course the most serious of the known toxic effects of streptomycin. There appear also to have been serious reactions at the sites of injection, including abscess formation. When this heroic treatment was performed abandoned the change is described as "a veritable resurrection." The scheme of treatment was then changed: doses of the same order were given for only one week, which is described as the "phase of attack." This is followed by the "phase

<sup>1</sup> July 26, 1947, p. 136.<sup>2</sup> *J. Amer. med. Ass.*, 1946, 132, 4, 70.<sup>3</sup> *Ibid.*, 1946, 132, 778.<sup>4</sup> *Trans. Studies Coll. Physic. Phila.*, 1946, 14, 51.<sup>5</sup> *J. Amer. med. Ass.*, 1947, 134, 679.

of maintenance," during which smaller doses are continued by the intramuscular route only. If we understand Debré and his colleagues aright all the 46 survivors in this series are still receiving treatment, the duration of which now varies among them from 2 to 10 months. It must indeed, as they say, be difficult to know when to stop. Meanwhile a single ward which is more like a playroom owing to the liveliness of 46 children who ought to be dead must be a unique and very gratifying spectacle.

The ultimate prognosis in some of these patients must inevitably remain in doubt for some time. The hard core of success would appear to consist of 22 bacteriologically verified cases which have survived for 120 days or more. Deafness is recorded as a complication in 6 of them. The cell count in the cerebrospinal fluid has been found the most reliable guide to the state of the disease in these later stages. It is of course almost meaningless while intrathecal treatment is continued, since the drug itself causes a pleocytosis. A persistently raised protein content associated with failure to regain weight and activity suggests a block due to meningeal adhesions. It is particularly interesting that 6 such cases were operated on, with marked success in 2. This series takes us a long way further towards deciding whether streptomycin may or must be used in treating this disease. The provisional answer seems to be that no patient who has not reached the stage of coma should be denied its possible benefit. The best scheme of administration will probably not be decided on for some time. Meanwhile it is valuable to have the results of the new policy pursued here: maximal doses by both routes for a week only, followed by a maintenance dose intramuscularly. It may be doubted whether continuation beyond ten or perhaps six months or even less will ultimately be found worth while. It is known that *Mycobacterium tuberculosis* often acquires streptomycin resistance during prolonged treatment, and success may well depend on killing a high enough proportion of the bacilli within the first few weeks. Estimations of the degree of resistance of bacilli cultivated post mortem from late fatalities should give important information on this point.

### HIGH-TEMPERATURE SHORT-TIME PASTEURIZATION

Before the war only one method of pasteurizing milk was officially recognized in England and Wales. This was the so-called "holder process," in which the milk is held in a closed container for not less than 30 minutes at a temperature of 145–150° F. (62.8–65.6° C.), after which it is cooled to a temperature of 55° F. (12.8° C.) or below. The plant required for this process is bulky and expensive, and the time spent in filling and emptying the holder tank, in addition to the holding period itself, is considerable. During the warm summer of 1940 so much raw milk went sour before it reached the public that in the national interest measures had to be introduced to prevent further waste of a highly important article in the nation's dietary. Two steps were taken. With the assistance of the Ministry of Agriculture and the larger dairy companies the Ministry

of Food sponsored an experiment for testing the keeping quality of milk. As a result a national milk-testing and advisory scheme was established by the Ministry of Agriculture, having the double object of educating the ignorant or careless farmer and protecting the creameries by allowing them to reject milk of very poor keeping quality. In the second place permission was given for the use of an alternative method of pasteurization that demanded less bulky and costly plant and that dealt with a much larger quantity of milk in a given time than the holder method.

The new method—High-Temperature Short-Time (H.T.S.T.) process—had been developed mainly in the U.S.A., where it had been officially recognized by certain health authorities for many years. The Ministry of Health regulations<sup>1</sup> governing its use in England laid down that milk to which the special designation "pasteurized" was applied should be retained at a temperature of not less than 162° F. (72.2° C.) for at least 15 seconds and be immediately cooled to a temperature of 55° F. (12.8° C.) or below. Since the method is a continuous flow process special injunctions had to be issued that the apparatus should be thermostatically controlled and be provided with a device that should automatically divert the flow of any milk which had not been retained at a temperature of 162° F. (72.2° C.) or over for at least 15 seconds.

Some concern was felt at the time about whether the safety margin of the H.T.S.T. process was as great as that of the holder process. It is true that laboratory observations had shown that the time-temperature combination enjoined was sufficient to bring about approximately the same degree of bacterial destruction as that caused by holding milk at 145° F. (62.8° C.) for 30 minutes, but no account had been taken of the lag period of response of the two main controlling instruments in the commercial plant, the automatic thermoregulator and the flow diversion valve. If, for instance, the lag period of these instruments was half a second, then one-thirtieth of the milk might pass through the heating section without being exposed to the full temperature of 162° F. (72.2° C.) for the whole time of 15 seconds. It was pointed out that reduction in thermometric lag might be achieved by the use of the thermocouple,<sup>2</sup> but it has been found that the speed of the thermocouple is too fast to enable the more slowly reacting heating system to be adjusted to it. However, the latest type of mercury-in-steel thermometer has a lag period of under half a second. The introduction in 1944 by the Ministry of Health<sup>3</sup> of the phosphatase test as a statutory test for the control of pasteurized milk was soon followed by the accumulation of results showing that the processing of the milk by the H.T.S.T. method was, in general, as satisfactory as that by the holder method. Even this, however, was insufficient to convince all dairy experts of the safety of the new process. Mr. Enock<sup>4</sup> drew

<sup>1</sup> Milk (Special Designations) Regulations, 1941, and Circular No. 2423, Ministry of Health, London.

attention to the almost complete absence of information on the effect of the H.T.S.T. process on the survival of tubercle bacilli under practical operating conditions. In the laboratory tubercle bacilli in milk are destroyed by exposure to a temperature of 162° F. (72.2° C.) in 9 seconds, or to a temperature of 159° F. (70.6° C.) in 15 seconds, but owing to the uneven flow of fluid through the heating pipe or plates it could not legitimately be concluded that in commercial processing the same results would follow; though it should be added, in parenthesis, that many dairy firms attempt to compensate for possible under-exposure by heating the milk to 162.5° F. (72.5° C.) for not less than 16 seconds. The fact, however, that the destruction of phosphatase in milk requires a slightly greater degree of heat than does the destruction of tubercle bacilli, and that the phosphatase test is usually negative on milk pasteurized by the H.T.S.T. method, led most workers to conclude that the objection raised by Mr. Enock was more of academic than of practical significance. In a matter, however, of such importance, it was felt that no doubt should be left, and the Chief Chemist to United Dairies, Ltd., therefore arranged with Dr. Porteous, of St. Mary's Hospital Inoculation Department, for a series of tests for tubercle bacilli to be carried out by the guinea-pig inoculation method on bulked milk before and after pasteurization by the H.T.S.T. process. The results are recorded in a letter to the Editor which we print on page 927.

Samples were taken from three different plants over a period of two years. Altogether 129 samples of milk that had been found to contain tubercle bacilli before processing were taken after pasteurization; every one of these responded negatively to the phosphatase test and was shown to be free from tubercle bacilli. This evidence indicates that in properly designed and properly operated plants of the H.T.S.T. pattern there is little risk of tubercle bacilli surviving the heat treatment. It is nevertheless dangerous to generalize too freely from limited observations, however conclusive their results may be. It is more difficult, for example, to make sure that the regulations are being complied with in an H.T.S.T. than in a holder type of plant, and undue reliance has therefore to be placed on the results of laboratory tests. These, of course, are based on the examination of samples representing only a minute fraction of the total amount of milk processed, and, if negative, can do no more than show that the milk at the time at which the particular samples were taken was being satisfactorily heat-treated. Moreover, trouble is occasionally met with in carrying out the phosphatase test, due to unsatisfactory quality of the chemical reagents, to the growth of phenol-producing organisms,<sup>5</sup> to the presence of bacteria capable of hydrolysing the substrate,<sup>6</sup> or to some other cause, leading in inexperienced hands to a possible false result. It would probably be wise, therefore, for health authorities to ask for a guinea-pig inoculation test to be carried out on a proportion, say 5%, of the pasteurized and heat-treated milks that they submit to the laboratory for examination, in order to make sure that the processing method, of whatever type it may be, is doing what it is in fact intended to do—namely, destroying all pathogenic organisms of importance in the milk.

## PENICILLIN IN SCARLET FEVER

Recent reports advocating the use of penicillin in the treatment of scarlet fever make it worth while considering the nature of the problem to be attacked. Three factors must be borne in mind. To begin with, many of the initial signs and symptoms, such as rash, vomiting, oedema of the throat, and lymphadenitis, are almost certainly manifestations of a specific toxæmia calling for the early administration of a potent antitoxin. But even when shorn of its toxic element the disease process is not inactivated; the streptococci have not been bereft of their invasive power, and the patient may still develop otitis media or sinusitis as an extension of his tonsillitis. Finally, although he may have acquired some resistance to his own infecting organism, in the usual open ward he may be further subjected to persistent bombardment by the streptococci of his bed-mates, and a "late" otitis or sinusitis may further prolong his illness. The three risks of scarlet fever, then, are the primary toxæmia, the early endogenous invasion, and the late exogenous reinfection, and no one treatment is likely to combat all three. Thus antitoxin is often regarded with disfavour because otitis media, for which it bears little responsibility, still occurs after its administration. At present, when we are dealing for the most part with a disease in which the toxic element is not predominant, it should be appreciated that the effects of streptococcal invasion, whether primary or secondary, are of the greatest importance. Unfortunately, the sulphonamides cannot be relied on to deal with this invasion. Some workers have considered them of value, but French,<sup>1</sup> whose experiment was carefully controlled, was unable to show real benefit in cases of scarlet fever, and her study has never been effectively refuted. It is hard to say what this relative failure should be ascribed to, but despite the American work on chemoprophylaxis it seems possible that sulphonamides taken orally have little effect upon the tonsillar infection save to drive the organisms temporarily underground, only to reappear when treatment is stopped. Another point is that the inhibiting effect of pus, the natural sequence of streptococcal invasion, limits the value of sulphonamides in such conditions as sinusitis and otitis media.

Penicillin overcomes the latter disadvantage, yet presents other problems. Meads and his colleagues<sup>2</sup> studied a small group of cases and found that local therapy was inferior to parenteral; they regarded treatment for at least seven days as essential. Jennings and De Lamater<sup>3</sup> record the results of different methods of treatment in cases of scarlet fever infected with a type 17 *Str. pyogenes* resistant to sulphonamides. With such a pure strain infection no difficulties arose from cross-infection with different types, although, since the patients were all treated in the same ward, reinfection was still possible. When patients were given a daily dose of 100,000 to 200,000 units of penicillin for less than four days throat swabs became consistently negative on culture in only 6 out of 47 cases. When doses of the order of 400,000 units daily were administered over periods of from two to seven days cultures from 15 out of 24 cases became negative. In this penicillin-treated group 7 examples were seen of otitis media or mastoiditis: 3 had begun before penicillin was started, 2 occurred after the treatment had stopped, and 2 developed during its administration.

<sup>1</sup> *J. Hyg.*, 1945, 59, 581.

<sup>2</sup> *J. Amer. med. Ass.*, 1945, 129, 715.

<sup>3</sup> *Amer. J. Med.*, 1947, 2, 1 (Jan. 1).

<sup>4</sup> *British Medical Journal*, 1947, 2, 538.

<sup>5</sup> *J. Infect. Dis.*, 1945, 57, 68.

Though this therapeutic trial had many imperfections, certain conclusions may be inferred. Parenteral doses of penicillin of the order of 0.5 mega unit a day must be given for at least a week to be effective in ridding the patient rapidly of his streptococci. Such a dose may seem unnecessarily large, but sterilization of the tonsils does present peculiar difficulties which have already been noted in the treatment of diphtheria carriers with penicillin.<sup>4</sup> Even this dosage will not clear the throat of streptococci in all cases, and a few persistent carriers must be expected. In open wards such carriers would constitute a continuing danger to their companions. It would seem desirable, therefore, when penicillin treatment is stopped to search for these resistant cases and remove them from the ward. In this connexion the valuable work of Hamburger and his colleagues<sup>5</sup> on the nasal carrier should be recalled. Further, during their continued stay in the open ward even those who responded initially should have their throats swabbed again from time to time so as to detect early any patient who relapses. In this way the incidence of complications due to primary invasion should be diminished, and by effecting a reduction in the load of *Str. pyogenes* in the air of open wards some of the late complications of scarlet fever should be prevented.

### COSMIC RADIATION AND CANCER

The suggestion that cosmic radiation, to which mankind is permanently exposed, may contribute significantly to carcinogenesis, as it has already been shown to contribute to the production of mutations, is not one which can be ruled out without investigation, however discouraging such a conclusion might be. It is probably because of the virtual omnipresence of cosmic radiation that the question has not before been put to the test. An attempt which has lately been made by Dr. F. H. J. Figge at the University of Maryland<sup>1</sup> is described by the author as preliminary, and his experimental results should therefore be regarded rather as a pointer to further investigation than as a demonstration against which no criticism could be advanced. The experiment consisted in a comparison of the latent periods of groups of methylcholanthrene-injected mice when kept in cages on different floors of a six-story ferro-concrete building and with or without one or more quarter-inch lead plates above their cages. The effect of the lead plates would be to distribute the energy of incident radiation among a larger number of particles, which individually would be of lower energy, and it might be expected that the more massive members of the building would also contribute in lesser degree to this effect. Also, since the controls, with two exceptions out of 67, all developed tumours within the 22-weeks period of observation, the measurement was one of increased speed of development rather than of increased incidence. Three groups, totalling 65 mice, without lead plates averaged a latent period of 11.3 weeks; four groups, totalling 88 mice, with one lead plate, 8.7 weeks; and the remaining group of 22 mice, with two lead plates, 7.5 weeks.

Criticism could be advanced both against the small numbers of mice used in the experiment and the absence of physical information as to the variation in radiation between different groups. Also, as the author himself points out, it is clearly desirable that control observations should be made in a heavily protected laboratory in which effective exposure to cosmic radiation is substantially reduced. At least one such laboratory is avail-

able in Great Britain, and it may well seem that a sufficient case has been made out for Figge's suggestion to be followed up. It would also be of interest to compare the natural incidence of cancer in human populations at sea level and at high altitudes—for example, Quito in the Andes and the Tibetan plateau. Figures for the former are no doubt available, but whether they could be regarded as comparable in the absence of some special and long-term investigation might be open to question. In the meantime it should perhaps be made clear that, although a ferro-concrete building formed part of Figge's experimental arrangements, his figures give no indication of any significant difference between the results of residence in the top or bottom of the building.

### PETROL FOR DOCTORS

The General Practice Committee of the B.M.A. has recently discussed with the Minister of Fuel and Power the effect on the medical man of the discontinuance of the basic petrol ration. Medical men naturally expect to share with the rest of the community the various hardships to which we are these days all exposed. But the motor-car is very much a part of the doctor's professional equipment. The doctor, and especially the general practitioner, is to all intents and purposes on duty twenty-four hours of the day. His opportunities for leisure and relaxation are few. It is, therefore, all the more necessary that he should seize what chance he may have of a break from work whenever he can, and no member of the public, we are sure, would grudge him this. Even when a doctor does break off from work he knows that he may be suddenly recalled by a patient in urgent need of help. It would seem, therefore, reasonable that a doctor should be able to go to a club or a cinema by car so that he can respond to a call on his services with the minimum of delay. The Minister of Fuel and Power has met this reasonable request of the General Practice Committee in a reasonable manner. The Minister rightly insists that a doctor using his car for social and recreational purposes should leave at his house exact information as to his whereabouts. And if a doctor has made alternative arrangements for his patients it would be clearly unjustifiable for him to use his car for social purposes. Regional Petroleum Officers have also been instructed that petrol may be allowed for doctors to attend B.M.A. and other professional meetings in their locality. As the Minister of Fuel and Power has recognized the special position of the doctors as consumers of petrol, medical men will, we feel sure, respond by not abusing the special facilities granted them.

### THE MINISTRY'S HEARING-AID

Deafness may be prevented or cured by medical or surgical measures; its disabilities may be lessened by education or alleviated by mechanical devices. This natural division of the practical problems of deafness underlies the planning of the three Committees on deafness appointed by the Medical Research Council in April, 1944: the Medical and Surgical Committee, the Educational Committee, and the Electro-Acoustics Committee. The responsibilities of the last-named have been particularly heavy, concerned as they have been with the design not only of electrical hearing-aids but also of audiometric equipment for the accurate assessment of deafness. The recent publication of the

<sup>1</sup> Science, 1947, 105, 323.

Committee's report,<sup>1</sup> completed in April, 1946, has been awaited with keen interest by all concerned with the welfare of the deaf. The Committee's problems have throughout been essentially practical ones demanding practical solutions, solutions moreover which could be based only upon the results of an extensive programme of investigation and experiment.

In the field of hearing-aid design the Committee has had to face the fact that the high cost of electrical hearing-aids has in the past debarred many from using them, a fact dependent in large measure upon the multiplicity of designs and methods of manufacture of commercial instruments. At the outset of its work, therefore, the Committee tried to find answers to two questions: first, was it possible to design a single type of hearing-aid suitable for the majority of deaf persons?; secondly, could such an aid be constructed in a form suitable for mass production? Theoretical considerations and the results of practical tests on various deaf subjects indicated the probable lines upon which such an aid should be designed; models were constructed, and their value was confirmed by means of extensive clinical trials. In the course of this work it was necessary to carry out comparative trials of a wide range of commercial hearing-aids, both British and American. As a final step several models of hearing-aids were constructed at the G.P.O. Research Station in a form suitable for mass production.

The M.R.C. Report contains a remarkable amount of technical information on the construction, performance, and instrumental testing of hearing-aids, and provides a close study of the principles and practice of their clinical testing. The tests developed by the Committee and fully described in the Report represent a well-considered combination of otological and telephone engineering practice, and it is hoped that they will find wide acceptance by otologists and others who prescribe hearing-aids.

Inquiries by the staff of the Social Survey into the incidence of deafness have been of much help in assessing the magnitude of the problem of the supply of hearing-aids in this country. These inquiries, initiated by the Medical and Surgical Committee on Deafness of the M.R.C., are designed to reveal not only the incidence of deafness in the various age groups but also its correlation with occupation, economic status, and aural pathology. The methods of the survey have been based upon the work of Beasley and his collaborators of the United States Public Health Department, and it is of interest to recall that, according to one of Beasley's many outstanding findings, some 1.2% of the population of all ages suffer from degrees of deafness disabling them from ordinary conversation. The findings to date of the Social Survey show that the corresponding figure in this country is at least as great; this suggests that there are half a million or more persons in this country who may benefit from hearing-aids. It is, however, necessary to stress that many of the deaf included in this number belong to the higher age groups. In them deafness is often due to senile and other degeneration of the internal ear, and so can seldom be satisfactorily corrected by electrical hearing-aids. The preface to the Report gives a timely warning against any expectation on the part of the deaf and their advisers that the hearing-aids recommended by the Committee are likely to prove of universal application; commercial hearing-aids will no doubt be a necessary supplement to the official models.

The Ministry of Health (*Journal*, Nov. 29, p. 893) is acting on the Committee's recommendations, and has made arrangements through the Ministry of Supply for the

manufacture of large numbers of hearing-aids constructed in accordance with the Committee's specifications. With the coming into force of the National Health Service Act in July of next year these aids will be available at otological clinics throughout the country, and will be issued free on the recommendation of otologists to all deaf subjects shown to benefit from their use.

These measures for the relief of established deafness are of great practical importance, yet the early diagnosis and accurate measurement of deafness are no less vital both for prevention and for the control of treatment. The Committee's careful investigation of pure-tone audiometers, described in the second part of the Report, is therefore of particular significance. It is hoped that the proposal of the Ministry of Health to provide standardized and well-calibrated audiometers will have the effect of raising the standards of otological work throughout the country.

### WHY PEEL?

After declaring that "it is essential to eliminate to the maximum practicable extent the wastage that occurs in the peeling and preparation of potatoes in the kitchen," the Minister of Education tells local education authorities in an Administrative Memorandum<sup>1</sup> how to peel potatoes. The Minister asks them to give strict instructions that potatoes should receive the briefest treatment in electric peeling machines "consistent with rendering them palatable," and that hand peeling and "cyeing" should be done with special care—indeed, the latter may be omitted if doing so does not cause potatoes to be wasted in the dining-room. The Memorandum adds that potatoes baked in their skins should be served as often as possible and experiments conducted with potatoes steamed in their skins.

The proportion of potato removed by peeling has been estimated as between 3 and 25%, an average being 14 to 16%,<sup>2</sup> and these peelings, of course, include part of the tuber's cortical layer. Moreover, potatoes boiled in their skins lose far less nutritive matter than peeled potatoes cooked in that way, and while there is a food shortage it is illogical to destroy a barrier that is "so resistant to high temperatures, and so absolutely impermeable."<sup>3</sup> Education authorities should try to persuade children to eat unpeeled potatoes.

We regret to announce the death on Dec. 1 of Sir John Fraser, Principal of Edinburgh University and Surgeon to the Edinburgh Royal Infirmary.

Mr. Aneurin Bevan, the Minister of Health, met the Negotiating Committee on Dec. 2 and 3.

Sir Arthur MacNalty, D.M., F.R.C.P., will deliver the FitzPatrick Lectures on "The History of State Medicine in England" before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday, Dec. 9, and Thursday, Dec. 11, at 5 p.m. In his first lecture he will discuss the medical department of the Local Government Board, and in his second the foundations of the National Health Service.

## RESETTLEMENT FROM A BASE HOSPITAL

BY

MARGARET J. MAYFIELD

*Almoner, Harefield County Hospital, 1940-6*

Sir Reginald Watson-Jones has described the Disabled Persons Act as "one of the great social reforms in the history of this country." The two novel features of the Act are the importance attached to the welfare of the individual disabled person and the co-operation demanded from those concerned with his employment.

The circumstances which led to the passing of the Act are worth recalling. The national situation of 1940-1, with its unprecedented demands upon man-power, drew attention to the possibilities of employing the disabled. To further this end the

Other patients were discharged still unfit and, as there is no out-patient department, were referred to other hospitals. The numbers are small, and form only 1.5% of the 7,920 admissions for that period; but it cannot be stressed too strongly that the few who do require assistance frequently require a great deal, and over a long period, before their resettlement can be said to be satisfactorily completed.

Space does not permit the reproduction of a detailed chart giving the history of each individual patient, but it is possible to draw certain conclusions from the following abbreviated analysis. The patients have been classified according to diagnosis, though this presented some difficulty as many were suffering from more than one complaint. Where this has been the case they have been classified under the most disabling condition.

The findings of the follow-up are divided into two sections (see Table). The first deals with the jobs held at the end of one year's follow-up and the methods by which those jobs were

Interim Scheme of 1946 was established, with its provision for special officers of the Ministry of Labour to guide the disabled into employment. During the war years these officials had a relatively simple task, as the demands of industry, especially the lighter varieties, readily absorbed an immense number of disabled persons. With the coming of peace, however, labour conditions are changing, and a much higher degree of skill will be required. To demonstrate this thesis a follow-up of disabled patients was undertaken.

## Follow-up of Disabled Persons

The patients that have been selected for this follow-up constitute the first 121 cases referred to the Ministry of Labour on Form R.D.1 by medical officers, and these have been followed up for one year. The actual period of the survey dates from Jan. 1, 1942, to June 30, 1946. It must be noted that these 121 patients are not the only ones who required assistance with employment. For many, slightly adjusted hours, a change of work, or special dietary considerations were all that was necessary, and this could be achieved by a direct approach to employers.

obtained. The second deals with the physical condition at the end of the follow-up. Record was also kept of the number of relapses during the follow-up period, as this is of great significance to employer, patient, and doctor alike.

## Placing the Disabled in Industry

It will be seen from the table that out of the total number of 121 cases, all of whom were referred to the Ministry of Labour, only 23 (approximately 19%) at the end of the follow-up period were in jobs arranged through the Ministry. By far the greatest number, 67 (approximately 55%), had placed themselves, while for 11 (9%) the arrangements had been made by other agencies. From their letters the majority appear to have reported to their exchanges, but on not being offered suitable work made their own arrangements—a comparatively simple matter owing to the greater opportunities for absorption into industry during the war years. Out of the 82 who were well and working at the end of the follow-up, only 19 were in jobs arranged by the Ministry of Labour, 56 had placed themselves, other agencies had placed 5, and 2 were still training.

A brief study of the relapse rates is also revealing. Out of the total number of relapsed cases (30) during the follow-up period 8, including 3 of the trainees, occurred among those placed by the Ministry of Labour, and 16 among those who had had made their own arrangements; 5 of those placed by other agencies relapsed, and the remaining case, suffering from peptic ulcer, relapsed soon after discharge from hospital, and attributed this to the worry and uncertainty of finding suitable work.

Further investigation into the progress of patients who undertook Government trainings tells the same story. In addition to the 4 who were training at the end of the follow-up period 7 others had training arrangements made for them, making a total of 11 for the survey. Only 4 (chest injuries 2, bronchiectasis 2) completed their training, and these were placed satisfactorily by the Ministry of Labour. The remaining 3 abandoned their training and made their own arrangements. Of those who had received Government training 4 relapsed during the follow-up period. Of this number a girl who had had a lobectomy for bronchiectasis had to give up her clerical training as she had a recurrence of sputum, thus making it difficult for her to work in an office in close proximity to others; another, an ex-Service man suffering from rheumatoid arthritis who had undertaken a training in tailoring, had relapsed by the end of the year, as also had another suffering from pernicious anaemia, with subacute degeneration of the spinal cord, who had been recommended for welding. The other who relapsed suffered from head injuries received at El Alamein; he attempted courses in carpentry and typewriter mechanic's work, both unsuccessfully, and finally made his own arrangements to train with a local boot- and shoe-repairing firm, the Ministry of Labour making an allowance.

#### Difficulties Met With

It must be stated in fairness to all concerned that, owing to various causes, the absorption of disabled persons into industry is no easy task. To cite one difficulty which arises in the Home Counties: the congestion of factories and offices in the central London area necessitates many persons living a long distance from their work, thus adding considerably to the fatigue factor. In some trades it is the organization itself which makes it impossible for the conditions of work to be adjusted to the needs of disabled persons. It is significant that among the 17 patients treated for peptic ulcers 16 were manual workers—e.g., lorry-drivers, builders' labourers, etc.—so that it was impossible for them to have special dietary consideration, and long-distance travelling prevented their returning home for a properly cooked midday meal. Seven out of the total number of relapses were gastric patients. It has been argued that these patients should change their jobs; but many, particularly among the older men, find it hard to make the necessary mental effort, or feel they cannot face the economic uncertainties of an unfamiliar job. These difficulties cannot be solved by the Ministry of Labour alone, but much more could be done by them with properly trained personnel, less cumbersome machinery, and a more thorough follow-up. A much higher degree of co-operation between hospitals, the Ministry of Labour, and industry is also required. The subsequent history of Mr. S. (aged 50) illustrates these points.

This man suffered from pernicious anaemia with subacute degeneration of the spinal cord, and could walk only with the aid of sticks. The Ministry of Labour undertook to find training for him successively in welding, in boot- and shoe-repairing, and in clerical work, all of which for various reasons were found to be impracticable, resulting in months of delay, prolonged stay in hospital, and bitter disappointment to the patient. It was finally suggested by the hospital authorities that the best form of resettlement might be a rug-making business at home—work he had been trained to do in the Occupational Therapy Department. The Ministry of Labour agreed to this, but it was left to the hospital social service department to make the arrangements with the Board of Trade and the retailers for the supply of wool, to raise the capital, and find the market for the rugs.

This instance betrays a deplorable lack of understanding of the needs of a disabled person and a superficial handling of the whole case. Far too often it happens that the importance of the social background is ignored and that the patient is regarded more as a means of production than as a human being.

Another difficulty that arises from this lack of understanding is with those who for economic reasons are forced to take an unsuitable job rather than face an indefinite period off work. The official mind does not always appreciate the difficulty of managing on the somewhat meagre unemployment benefit.

Some might say that the disability of Mr. S. and of several others mentioned in this survey was severe, and that possibly those who were not able to work or who died within the year should not have been referred to the Ministry of Labour; but it can be argued, on the other hand, that work is of high psychological value to many persons who, if told they could never work again, would deteriorate mentally. The task of providing work for this category of severely disabled persons has now been taken over by the Disabled Persons Corporation, provided for under the 1944 Act. They have power to create sheltered workshops and to subsidize existing ones; but, although this would appear on the surface to be the ideal solution for many cases, a word must be said concerning residential workshops. While appreciating that much good work is done in them, and that they fulfil a need for a certain type of patient, particularly the young chronic tuberculous subject who can never adjust himself to normal surroundings, it cannot be said that they provide the best solution for disabled persons in general. The great majority do not wish to uproot themselves and leave their homes and friends, and a happier answer to the problem would be more facilities for work in sheltered workshops locally or in their own homes. Ideally, these workshops should provide for part-time work and a graduated return to employment as well as the right type of work under good conditions. From the industrial aspect it would not be an economic proposition to employ many such patients and pay a living wage, but one hopes to see an extension of the principle of the supplementation of wages, at present payable only to certain types of the tuberculous.

The second weakness observed in this survey—namely, the cumbersome machinery of the Ministry of Labour—is clearly shown in the attempts to arrange trainings. Eight weeks elapsed between the recommending of the boot- and shoe-repairing training for Mr. S. by the D.R.O. and the date when he was informed that it was impracticable. It took all this time to ascertain that there were no facilities for training either in a centre or with a local employer, and no adequate supplies of leather to make it an economic proposition. Mr. D., suffering from spondylitis and tuberculosis, had a similar experience. He waited five weeks before being told there was no clerical training available.

It is appreciated that the pooling of information regarding local labour conditions presents difficulties, particularly when the situation is complicated further by an uncertain prognosis and the patient's capacity for employment cannot be accurately assessed; but much more could be done, and must be done, if the value of the hospital interviews is not to be lost. This is rendered more urgent by the coming days of regionalization.

The need for a more thorough follow-up has already been illustrated by the foregoing examples. Without someone behind to advise and assist, Mr. S. with his lack of education would never have struggled through the ramifications of the Board of Trade to final independence. It could be argued that had he applied to the Ministry of Labour he would have received the necessary assistance; but anyone acquainted with the psychology of sick persons knows that many, for reasons of pride or from timidity of nature, do not take the initiative in asking for assistance. It is realized that the Ministry of Labour has not the same facilities for follow-up as a department of health; but if the responsibility of employing disabled persons is to be theirs they must devise some method of maintaining contact with the patient, especially in chronic conditions prone to relapse. For other reasons, too, such as research, a comprehensive follow-up would be valuable.

No survey of resettlement would be complete without mention of the difficulties caused by compensation and pensions. Without doubt these can be a stumbling-block in a patient's rehabilitation, as he fears that by taking up employment his compensation will be less, and there is the additional risk that after a prolonged period of enforced idleness he will become unemployable. Evidence indicates, however, that this is less of a burden than it was, as out of the 121 cases in this survey only

one who suffered from asthma and remained well but was not working throughout the year can be said to come within this category.

### A Brighter Future

Those of us who are concerned with the employment of disabled persons know the magnitude of the task, but events during the past few decades, culminating in the passing of the Disabled Persons (Employment) Act, suggest an infinitely brighter future. Improvements in employment conditions in general can only be achieved slowly, but already a large number of firms show a benevolent interest in their employees, which leads one to hope that in time there will be a more generally enlightened attitude towards the needs of the disabled. A solution to all the difficulties is provided by the Disabled Persons (Employment) Act, and the key to its successful implementation lies in the recognition of the importance of the individual. As no two persons are endowed with the same qualities of character or talents, so any scheme which attempts to rehabilitate *en masse* is doomed to failure. The patient himself must make the final decision, but much of the responsibility lies with those who advise him, and there must be closer co-operation between medicine and industry. The passing of the Disabled Persons (Employment) Act, a direct consequence of the war, will manifest once again the truth of Shakespeare's words that

"There is some soul of goodness in things evil,  
Would men observingly distil it out."

## HOSPITAL RECORDS\*

The course-conference for hospital records officers held at Oxford in September provided, so far as is known, the first opportunity for persons engaged or interested in hospital medical record-keeping in Great Britain to meet and exchange information and opinions on matters relating to hospital medical records.

Although originally planned for "hospital records officers or their equivalents" (i.e., lay persons who, though not designated records officers, actually carried out duties connected with the production and care of medical records), the course-conference members included two hospital medical superintendents, a surgeon, three bio-statisticians, several hospital administrators and assistant administrators, and others not solely (or even directly) engaged in the work of a hospital records department. A few of those attending were not in hospital service at all, but were concerned either with medical records in the wider sense or with records in some medical organization other than a hospital. Among those wholly or partially employed on hospital medical records there was revealed a wide range of duties and functions, some controlling records from registration to final disposal, others being in charge of one aspect only of record-keeping. The various interpretations placed on the title "records officer" were of interest in themselves.

The total number of registrants was 100, and 12 applications had to be declined owing to shortage of accommodation. Seventy hospitals were invited by letter in May, 1947, to send representatives. Of these, 63 availed themselves of the invitation. The remainder of the hospitals represented applied for places on their own initiative. This was naturally most encouraging to the organizers.

Papers were given by some 30 persons, and seven commercial firms provided material for demonstrations. The paper contributed by Miss Elsie Royle, of the Christie Hospital, Manchester, was outstanding. Dealing with the duties and responsibilities of records officers, Miss Royle's paper called for a high standard of work from her colleagues. "The qualifications of a records officer," Miss Royle said, "include all the virtues of tact and diplomacy, initiative and energy, good humour and patience, a progressive outlook, and the ability to organize and to teach. To these personal attributes a knowledge of medical terminology, anatomy and physiology, and an appreciation of statistical theory should be added, and last, and probably most important, experience in hospital and medical ethics." Miss Royle's main theme was that the

medical profession needs trained help in the analysis and presentation of the results of its hospital work, and that if hospitals are to have good medical records and to use them intelligently someone must organize their preparation and analysis. This organization is a task for which clinicians have insufficient time. Hospitals should therefore entrust it to a trained person, and all the work connected with records should be concentrated in the hands of this specialized officer.

The same note was struck by Mr. H. Cotton, of the Nuffield Bureau of Health and Sickness Records, Oxford, who described the purposes and uses of medical records in hospitals. In the course of his opening paper Mr. Cotton observed:

"The main need to-day is for a broadly uniform system of medical record-keeping in British hospitals. If record-keeping is indeed a scientific task, the laws of the science should be discovered and generally applied. A uniform system would not mean regimentation. It would mean that certain well-defined principles would be followed by all hospitals, with adjustments best suited to individual requirements.

"It follows that if medical record-keeping is to have a broad plan, and if the best techniques are to be adopted by all concerned, there is a need for persons versed in the plan and skilled in the techniques. This means that the production and care of medical records should not be allotted haphazard to persons with no special aptitude, training, or experience. Trained medical records officers are essential members of modern hospital staffs."

Prof. J. A. Ryle addressed the course-conference, and, using examples from his own career as a physician, indicated how the absence of records, or the inability to use them, could be a very real handicap to a clinician, whether a junior or senior member of the hospital staff, a consultant, or one holding a public appointment. He emphasized the advantage of teamwork, and stressed that to-day the almoner and the records officer were just as much a part of the medical man's team as the pathologist, the physiotherapist, and others. In stressing the importance of follow-up (which should not be limited to a few special diseases) he pointed out how utterly dependent on accurate and readily accessible records was a successful follow-up scheme.

Dr. P. L. McKinlay, medical statistician to the Department of Health for Scotland, contributed a paper of special interest, dealing with records as potential data for statistics. Striking a note of caution, Dr. McKinlay pointed out that hospital records will provide information only on intercurrent morbidity, and we must not overestimate their capacity even in this respect. For instance, one result of certain modern drug therapy is that many diseases formerly treated in hospital are now being treated at home. Also, hospitals select their cases to some extent. The sickness of the community as a whole, therefore, is not reflected in hospital figures.

Other factors which have to be studied in assessing public health are predisposing factors, prognosis, and criteria of response to therapy. Hospital records can contribute some information regarding the first and second questions. Prognosis is more easily determined (from the community point of view) on data contributed by general practitioners throughout the area.

The hospital administrator's view of the records problem was put by Mr. Stephen C. Merivale, house governor of the Bristol Royal Hospital, who said that the position of the records officer was clearly that of a departmental head, responsible to a Records Committee, comprised almost wholly of medical staff, for all matters affecting records generally; and to the house governor for administrative matters affecting the hospital as a whole. The records officer should be responsible for the appointments system, the registration of all patients, the journeys of notes throughout the hospital, the allocation of typists and stenographers engaged on typing clinical notes and letters to outside practitioners, and the more generally recognized duties of filing, indexing, and analysing medical records. Where there is a medical library it should be under the records officer. If the best use was to be made of a hospital's beds a central waiting list should be compiled by the records officer, who, on the direction of the various clinicians, would initiate the admission of patients to hospital.

Other papers were given by Prof. Sir Hugh Cairns (Oxford), Mr. B. Pennington (L.C.C. Health Department, statistician), Mr. Edwin F. Patterson (King's College Library, Newcastle-upon-Tyne), and Dr. A. H. T. Robb-Smith (Oxford).

\*An account of a Course-Conference for Hospital Records Officers, held at Oxford in September, 1947, under the auspices of the Nuffield Bureau of Health and Sickness Records.

The subjects dealt with in a syllabus covering eight days included medical nomenclatures and classifications, unit records, diagnostic indices, appointments systems for patients, medical terminology, microfilming, medical and surgical dictation, and others of a more detailed interest. The course-conference was not invited to adopt any formal resolutions, and did not do so. Nevertheless, it is possible to summarize very briefly what appeared to be the views of those attending on certain points of principle. The following expressions of opinion appeared to command general assent:

1. In all hospitals, adequate documentation of medical service should be the rule.
2. In the larger hospitals at least, responsibility for the production and care of medical records should be assigned to a person (not necessarily medically qualified) skilled in this work. [N.B.—"Production" as here employed means the preparation (in part) and assembly of medical records, but not the entry of any clinical or technical data.]
3. The person to whom this work is assigned should be designated "Medical Records Officer" and should have the status of a departmental head.
4. The medical records officer should be qualified by training and practical experience for the work undertaken; the subjects studied should include anatomy, physiology, medical terminology, organization techniques, filing and indexing methods, photographic and microfilming methods, coding and classification, interdepartmental relations, interview technique, simple statistical methods, and, in some cases, punched-card methods.
5. There is a need for training facilities. One way of meeting this need initially would be by the establishment of training schools for medical records officers in one London hospital and one provincial hospital; the hospitals chosen should first be equipped with records departments of the most efficient and up-to-date kind.
6. A basically uniform system of medical record-keeping should be devised not to prescribe "pro-formas" for hospital doctors but to standardize methods of registration and techniques for the preparation, storage, and indexing of medical records.

The Nuffield Provincial Hospitals Trust sponsored the course-conference.

(A Digest of the Proceedings of the Course-Conference has been prepared, and copies may be obtained, price 2s. 6d. each, from Mr H. Cotton, 10, Parks Road, Oxford.)

### SPECIAL COMMITTEE ON NUTRITION

The Special Committee on Nutrition set up recently by the British Medical Association held its first meeting at B.M.A. House, Tavistock Square, London, on Dec. 1. The following are the members of the Committee:

Lord Horder, adviser to the Ministry of Food; president of the Food Education Society.

Dr. G. F. Buchan, until recently medical officer of health, Willesden; lecturer in public health, Guy's Hospital and St. Mary's Hospital Medical Schools.

Miss Harriette Chick, C.B.E., D.Sc., a member of the staff of the Nutrition Section of the Lister Institute of Preventive Medicine.

Prof. S. J. Cowell, professor of dietetics, University of London; a member of the B.M.A. Committee on Nutrition, 1933.

Prof. G. P. Crowden, O.B.E., D.Sc., professor of applied physiology, University of London; secretary, Nutrition Committee Medical Research Council, 1928-34; adviser to the B.M.A. Committee on Nutrition, 1933.

Sir Jack Drummond, F.R.S., D.Sc., scientific adviser to the Ministry of Food, 1939-46; director of research to Boots Pure Drug Co. Ltd. since 1946; adviser on Nutrition Control Commission for Germany and Austria (British elements), 1945-6.

Dr. R. G. Gordon, a member of Council, B.M.A.; chairman of the Science Committee, B.M.A.

Dr. Jean Mackintosh, senior assistant medical officer of health for maternity and child welfare, Birmingham; member of the Nutrition Society.

Prof. V. H. Mottram, formerly professor of physiology, University of London; a member of the B.M.A. Committee on Nutrition, 1933.

Dr. R. Murray Scott, general practitioner, Leeds.

Dr. R. E. Smith, medical officer, Rugby School.

Dr. H. M. Sinclair, director of Oxford Nutrition Survey.  
Dr. Donald Stewart, member of the Industrial Health Research Board, Medical Research Council.

Dr. J. G. Thwaites, general practitioner, Brighton; member of Council, B.M.A.

*Ex-officio* members of the Committee are:

Sir Hugh Lett, President, B.M.A.

Dr. J. B. Miller, Chairman of the Representative Body B.M.A.

Dr. H. Guy Dain, Chairman of Council, B.M.A.

Dr. J. W. Bone, Treasurer, B.M.A.

The Committee has power to co-opt additional members whose names will be published later.

The Ministry of Health has nominated Dr. H. E. Magee Deputy Senior Medical Officer in the Foods Division of the Ministry, to attend the Committee as observer.

The terms of reference of the Committee are: "To consider and report on the problems of nutrition in this country, including present nutritional standards."

On Dec. 1 Lord Horder was elected Chairman of the Committee and Dr. R. G. Gordon Vice-Chairman, and in Lord Horder's absence Dr. Gordon presided at this preliminary meeting. It was reported that four of those invited had found it impossible to accept membership, and the Committee discussed other possible nominations and also the desirability of obtaining by co-option the representation of certain special points of view. It was decided to endeavour to enlist as members of the Committee a statistician and a representative housewife.

Sir Jack Drummond suggested the appointment of three subcommittees. The first of these would be charged with the ascertainment of nutritional requirements, examining critically the existing knowledge and information concerning basic nutritional requirements of various sections of the population. The second would undertake a survey of family consumption, and Sir Jack hoped that with the co-operation of the Ministry of Food some access might be given to the immense amount of data accumulated by that Ministry during the war but never classified or published. The third would be an expert clinical subcommittee whose task would be to examine data concerning the state of health of the people in the war and post-war periods, studying not only clearly attested documents, such as the Medical Research Council's reports, but also in a critical way the mass of less clearly substantiated statements about the effect of war and post-war conditions of diet upon health. The Committee agreed to the setting up of these three subcommittees, and added a fourth, which would concern itself with practical dietetics, and would also consider questions of morale and psychology in relation to diet.

Five members of the Committee were appointed to each of these subcommittees, and the need for getting out a report with reasonable speed was stressed. It was considered that the first and second subcommittees, dealing with nutritional requirements and family consumption respectively, might find it desirable, in part, to work together.

The Committee as a whole will not meet again until reports from the subcommittees are available. Various documents were laid before the Committee, including the report of the former Special Committee of the Association on Nutrition, published in 1933. Two members of the present Committee—Dr. G. F. Buchan and Prof. V. H. Mottram—were also members of the earlier Committee, and another member of the present Committee—Prof. G. P. Crowden—assisted in its deliberations.

"Is chastity outmoded?" is a question asked in the November number of *Marriage Guidance*, the bulletin of the National Marriage Guidance Council, 78, Duke Street, London, W.1. The conclusion is that it is not supported by quotations from various authorities. The late Prof. Ernest Groves said, "Pre-marriage experience is not an advantage but frequently instead the chief cause of marital maladjustment." The opinion of Prof. Hornell Hart is also quoted: "The fear of some young people lest inexperience in sexual intercourse may leave them unprepared for marriage is groundless. . . . Pre-marital sex relations are likely to damage subsequent affection and to obscure the psychological and social aspects of the search for well-matched mates."

## Reports of Societies

### RADIATION IN THE TREATMENT OF MALIGNANT TUMOURS SWEDISH EXPERIENCE

At a meeting of the Section of Radiology of the Royal Society of Medicine on Nov. 21, with Dr. J. S. FULTON in the chair, Dr. ELIS BERVEN, of Stockholm, gave an account of the methods and results of radiation treatment of malignant tumours in Radiumhemmet.

Dr. Berven said that one of the principles followed was that radiation through the tissues surrounding the tumour must not be of such intensity as to damage the resistance of the body, and another was that treatment should be given in the shortest possible time. He described the x-ray and other apparatus employed, and said that 3,225 mg. of radium was distributed in 97 tubes and 14 applicators. Only gamma rays were used, and no radium emanation or radon was employed. Malignant melanoma, which was radio-resistant, was treated by excision under general anaesthesia, followed by prophylactic x-ray or radium treatment in the region. In carcinoma of the lip radium applicators had been used at first, and then implantation of radium needles, but now most cases were treated by x rays and 69% of patients were symptom-free after five years. In cases of carcinoma of the mouth radium applicators and implanted radium needles had given way to a combined method, beginning with telerradium through different ports of entry so as to give a cross-fire effect, supplemented later by x-ray treatment. Usually a small tumour remnant was left, and this was electrocoagulated under general anaesthesia. Cases of cancer of the oral cavity treated in this way in the period 1931-41 numbered 688, of which 196, or 28.5%, were symptom-free at the end of five years. He next spoke of the Plummer-Vinson syndrome. The atrophic state of the mucous membrane of the mouth seemed to predispose these patients to tumours of a malignant type. X-ray treatment was applied in four fields, two on each side, each field being given a total of from 2,000 to 3,000 r in daily doses of 400 r, and later telerradium was applied. For tumours of the oesophagus only palliative treatment could be undertaken.

In carcinoma of the antrum x-ray treatment was first given, covering two anterior and two lateral fields, with a total dose to each field of about 3,000 r. When the reaction had passed off, coagulation was performed not only in the antrum but in the ethmoidal region, and four radium tubes were applied to the coagulated area. Cancer of the maxilla was treated in the same way, and about 39% of cases remained symptom-free after five years. In cases of cancer of the nasopharynx the proportion of patients remaining symptom-free after five years was only 22.5%, but in sarcoma of the same region it was 44%. For infiltrating intrinsic cancer of the larynx laryngectomy was employed with post-operative radiation. The number of cases so treated in 1940-4 was 31, and freedom from symptoms for three years was claimed in 61.3% of the cases. In carcinoma of the lung or bronchus the treatment given had been only palliative.

Since 1921 cases of carcinoma of the breast had been treated by pre-operative irradiation of two fields (unless the breast was small, when four fields were employed, two on the breast and two in the axilla), and as soon as possible after operation a first course of radiation was given, two months later a second course, and after a similar interval a third. Post-operative treatment was applied over one large anterior field and one posterior field. During the period 1921-35 607 cases of cancer of the breast had received this sequence of treatment, and the proportion symptom-free after five years was 41.2%, and the proportion of survivors 44.3%. During the period 1936-41, when the technique was improved and x-ray castration adopted in all cases, 517 women had been treated, and 44.1% were free from symptoms at the end of five years and the survival rate at the end of five years was 52.6%. In cases of cancer of the breast with periglandular involvement treated by pre- and post-operative radiation, 32% were symptom-free after five years. During the period 1935-41 40 cases of carcinoma of the bladder were treated, and 12, or 30%, were free from signs and symp-

toms after five years. From 1929-40 167 cases of carcinoma of the prostate were treated; 107 of these were inoperable, and among these the survival rate after three years was 16%, and after five years 5%. In the operable cases the survival rate after three years was 38% and after five years 26%.

For cancer of the cervix the method followed since 1932 had been Heyman's, or the Stockholm technique. Radiation treatment had been given in two sessions; the total intrauterine radium application was 2,000 to 2,600 mg./hr., and the application in the vagina was about 4,000 mg./hr. In cases of carcinoma of the body of the uterus the method of packing the uterine cavity with small radium containers had been followed. Radium was applied in two sessions at an interval of two weeks. During the years 1934-41 459 cases had been treated in this manner and the number symptom-free after five years was 284, or 61.9%.

Dr. N. S. FINZI said that his impression was that better results in cases of cancer of the rectum were being obtained now with the million-volt apparatus than had been the case with the earlier relatively small power installations. The same was true of cancer of the antrum.

Prof. B. W. WINDEYER, expressing thanks to the lecturer, spoke of the help which the Stockholm institute extended to visiting radiologists from this country. Dr. BERVEN said that in Stockholm the closest co-operation existed between the radiologists and their surgical and specialist colleagues. They all met together on two days a week and usually had some twenty or thirty patients to discuss.

### BRITISH ORTHOPAEDIC ASSOCIATION ANNUAL MEETING

The annual meeting of the British Orthopaedic Association was held at Manchester on Oct. 24 and 25 under the presidency of Mr. GEORGE PERKINS.

#### Recurrent Dislocation of the Shoulder

Mr. H. OSMOND CLARKE described in detail a capsulorrhaphy for recurrent dislocation of the shoulder, which he called the "Putti-Platt" operation. This consisted in a wide approach to the front of the joint with division of the coracoid, subscapularis tendon, and capsule. The distal cut edge of the subscapularis tendon was sewn to the neighbourhood of the anterior lip of the glenoid, and the proximal portion of the tendon was made to overlap the suture line. The coracoid was repaired and the wound closed.

Mr. J. C. ADAMS had investigated the results, after two years or more, of 114 out of 159 operations for recurrent dislocation of the shoulder undertaken in Royal Air Force hospitals from 1940-5. After 59 Nicola operations there had been 21 recurrences and 2 after 37 Putti-Platt operations. The intervals before recurrence varied from four months to five years, averaging 22 months. Among 79 shoulders fully explored, the glenoid labrum was found detached in 69 and soundly attached in 10. Adequate radiography of 68 patients revealed a postero-medial defect in the humeral head in 56; an antero-posterior view with limb rotated inwards through 60-70 degrees was advised. The range of movement was almost full after Nicola's operation; lateral rotation was frequently diminished after Bankart's operation, and rather more so after the capsulorrhaphy. The relatively free range after Nicola's operation was perhaps a factor in the recurrent cases, which did not always show atrophy of the reattached tendon. The good results of the other operations were attributed to the fibrous tissue formed in the front of the capsule which limited lateral rotation.

Mr. A. L. EVER-BROOK gave a detailed analysis of 20 consecutive cases operated upon by the antero-medial approach. The lesions found were: anterior detachment of the glenoid labrum (Bankart's lesion) alone in 6 cases; a postero-medial defect in the humeral head alone in 3 cases; a combination of these two defects in 10 cases; and detachment of the subscapularis from the lesser tuberosity in one case. The bony defect was best revealed pre-operatively by radiography from above with the film in the axilla and the arm laterally rotated through 70 degrees. Radiography often disclosed also a bony subglenoid outgrowth in cases of Bankart's lesion. In cases

showing this lesion at operation, a modified Bankart's operation was performed. In cases not showing this but with a defect in the humeral head, multiple osteotomy of the coracoid had been performed (2 cases) and, more recently, an iliac graft had been applied to the front of the scapular neck. After operation the arm was bandaged to the side for four to six weeks. Work was resumed after a further six weeks. No recurrence had been found in 12 cases followed up for periods of six months to four years.

Mr. A. B. PAIN had examined the records of 43 operations for recurrent dislocation of the shoulder in 33 patients operated on in the Leeds area during the preceding fifteen years. One patient had bilateral operations, 7 others had two operations, and 3 had as many as three operations each; 6 of the patients were epileptic. Among 28 patients traced, seven different types of operation had been performed as follows (recurrences in parentheses): Clairmont 1 (1); Henderson 13 (9); subscapularis tenotomy 3 (1); Nicola 12 (4); Bankart's operation 2 (1); capsular plication 1 (0); and bone block 4 (0). Recurrence might happen at any time up to seven years after operation, but in 12 out of 18 instances it happened within a year and within three weeks in 6 of these cases.

### Other Papers

Prof. JACQUES LEVEUF, in a paper on the treatment of acute osteomyelitis, expressed the view that in haematogenous osteomyelitis the first bony lodgment of the staphylococcus was not usually in the metaphysis but in the neighbourhood of the entry of the perforating artery, where a cortical abscess formed, with usually a very small lamellar sequestrum. Spread was mainly towards the surface, but also along the artery and its branches, producing further cortical lesions and occasionally medullary ones. Prof. Leveuf, who has practised plaster-of-Paris immobilization in this disease for twenty years, condemns bone operations in the acute stage and especially metaphyseal drainage. The soft-tissue abscess should be drained between the fifteenth and twentieth days; formerly the wound was left widely open, but now, with the aid of penicillin, it was closed forthwith. He produced histological and radiological evidence in support of his pathological contention, which led to a lively discussion.

Prof. S. L. BAKER, in a paper on the histology of callus, stated that the first sign of bone appeared within the first week in an area of gelatinous oedema in the mass of young connective tissue which invaded the haematoma about a fracture. This bone was of a type called woven bone because of the irregular arrangement of the fibres which, with a connecting substance, formed the osteoid matrix, as distinct from lamellar bone in which the fibres had a parallel arrangement. Whereas woven bone could be laid down rapidly in connective tissue, lamellar bone formed slowly and could be laid down only on a surface. Woven bone formed about blood vessels and so the orientation of its trabeculae was determined by the vascular arrangement, whereas that of the trabeculae of lamellar bone was determined by the stresses to which it was submitted. Woven bone was usually replaced slowly by lamellar bone. The formation of cartilage in callus appeared to depend largely on movement. Callus was no respecter of the periosteum, often passing well outside it. In certain rare instances, especially in *fragilis ossium*, there was a prodigious formation of callus which might be taken for sarcoma.

Mr. BOLAND BARNES read a paper on paraplegia in cervical column injuries, based on 22 cases. Mr. D. LL. GRIFFITHS discussed the management of acute ischaemia in an injured limb. Mr. JOHN CHARNLEY gave a short discourse, illustrated by ingenious models, on some of the basic mechanical principles used in the reduction and splinting of fractures. Mr. C. H. CULLEN read a paper on causalgia, based on 24 cases seen personally during the war.

Mr. I. J. FAIRBANK, discussing fracture-subluxation of the shoulder, said that among 115 cases of fracture about the shoulder he had found 12 with radiologically demonstrable downward subluxation of the humeral head—in 11 of them as a complication of fracture of the neck of the bone. Clinically, a groove could be felt between the acromion and the humeral head which could usually be abolished by lifting the humerus actively or passively or by recumbency. In the

normal subject little downward subluxation occurred except during anaesthesia, and muscle tone appears to be the main factor preventing it. At follow-up, a year after injury, the subluxation had sometimes disappeared, but it occasionally persisted for three years or more. Of these patients 9 had been treated for their fractures with collar-and-cuff slings and 3 with abduction frames. It was suggested that, in the treatment of fracture of the humeral neck, a triangular sling was preferable to a collar-and-cuff, and that if abduction was necessary a plaster-of-Paris spica should be used.

In considering the treatment of the unreduced pathological dislocation of the hip from septic arthritis in infancy, Mr. A. F. BRYSON excluded patients aged more than twelve months at the time of the acute illness. In most it occurred in the first nine months. His 16 cases were all unilateral, and 15 were operated upon. One underwent an unsuccessful Colonna's arthroplasty. Of 3 treated by osteotomy, one secured stability, but the other two continued to show progressive shortening, flexion, and adduction. Arthrodesis was much the best procedure; in 11 patients so treated bony fusion occurred within a few months in 7 of them and after subsequent osteotomy in another. Operation should be delayed till the age of 12 or 13 years because of the great amount of activity possible till then and because earlier bony fusion was not only difficult to obtain but did not fully prevent subsequent flexion and abduction deformity.

Miss E. L. WILLIS summarized the end-results in fractures of the femoral neck in 192 cases treated in the University Department of Orthopaedics at the Manchester Royal Infirmary, with a death rate of 8% within three months of injury. Fifty out of 113 patients with subcapital and transeervical fracture were sent two or more years after injury: 22 had good results and 15 poor; 13 showed avascular necrosis of the femoral head. Of 74 fractures treated by Smith-Petersen nailing, 41 showed radiological union. Of 79 basal and pertrochanteric fractures, 51 were treated by well-leg traction, with union in 43. There were 23 good clinical results among 28 patients examined more than a year after injury.

Clinical cases were shown at the Manchester Royal Infirmary by Prof. HARRY PLATT, Mr. HENRY POSTON, Mr. D. LL. GRIFFITHS, Mr. JOHN CHARNLEY, Miss E. L. WILLIS, and Mr. T. J. FAIRBANK; and also at the Salford Royal Hospital by Mr. W. SAYLE CREEF, Mr. S. M. MILNER, Mr. J. L. MANGAN, and Mr. CLAUDE BRUN.

## THE PROBLEM OF DELINQUENCY

### COMMUNITY CONTROL OF THE INDIVIDUAL

The annual general meeting of the Institute for the Scientific Treatment of Delinquency, the first such meeting since 1940, was held at the Institute's new premises, 8, Bourdon Street, W.1, an eleven-roomed building with a lecture hall. Lord HORDER, vice-president of the Institute, presided.

Mr. WALTER ELLIOT, M.P., described delinquency as a deviation from the average—not from the normal, because it was not known what the normal was or ought to be. He felt that scientific investigators must often have qualms about the way in which the community was extending its sway over the individual and requiring conformity to a pattern. The House of Commons was continually manufacturing new offences. Scarcely a day passed without some fresh opportunity for delinquency being discovered. Examples were to be found in the National Assistance Bill. It was recommended to the House by Mr. Aneurin Bevan, and would shortly be the law of the land, that certain persons might, on the certificate of the medical officer of health, be removed from their homes to a hospital or some other place of detention, and any person who disobeyed or obstructed the execution of such an order would be guilty of an offence and liable to a fine not exceeding £10. Thus, without any scientific investigation, a new set of delinquencies would be instituted. Most of the prophets, nearly all the noble army of martyrs, and certainly every one of the hermits would have been subject to a fine not exceeding £10. Further, anybody living under conditions of vagrancy—he had in mind St. Francis of Assisi—might be liable to very drastic penalties.

The Institute, Mr. Elliot took it, was interested in the effect of community action upon individuals. One great mass experiment of this kind was wartime evacuation, and here a curious thing happened. He had some facts relative to the condition of 200 children who were transferred from a crowded industrial city of Lancashire to a country camp where they lived for two or three years in ideal surroundings and had every advantage in the way of diet and medical supervision that could be desired. Yet their increase in growth did not even equal that of a comparable group of youngsters who remained in the industrial environment. He could think of no better explanation than that the camp children had been separated from home and family life.

Another curious fact was the sudden cessation at the outbreak of war of the customary biennial explosion of measles. For years there had been between 1,800 and 1,900 deaths from measles every second year, the intervening year showing only about one-tenth the number, but this rhythm was decisively broken in 1939-40, apparently as a result of the closing of the schools, and now that the schools were again fully at work the rhythm was re-establishing itself. Another example of wartime waywardness was the suicide rate. Before the war the number of suicides was astronomically large. The number of men committing suicide in 1938 and in 1939 was about 2,500, but during the years 1942 to 1945 it was always below 2,500; in 1946 it rose to 2,500, and this year was again rising. It might be said that the conditions of war offered men an alternative to suicide, but the same trend was found among women. Women suicides numbered about 1,700 in 1938 and 1939, but from 1941 to 1944 they were round about 1,200, and they rose to 1,400 in 1945, to 1,600 in 1946, and this year the figure was still increasing. It seemed as though when settled conditions prevailed people became bored and were more likely to turn their thoughts to suicide. Apparently "bottle, murder, and sudden death" represented the desires of the human race, and a fundamental problem was what equivalent was to be offered for these conditions.

Mr. Elliot went on to say that the difficulty of our society was the pressure of enormous State mechanisms continually expanding and aiming to produce more and more settled and uniform conditions, while settled conditions were the things against which human nature rebelled. What was the remedy? Some of the figures he had quoted showed that at any rate the institution of the family was a very important one. One of the wisest epigrams ever coined in relation to the treatment of delinquency was Shaw's remark that "one should never strike a child except in anger." But it was very difficult for the State official to turn anger on and off, whereas the child's mother, or still more his father, could administer correction in such a way as not to harm the child and yet to vindicate the law of the normal—or rather that of the average—in the family.

He thought that a great humility was required in the approach to such problems, which were largely psychological. In his view the human race was being over-governed. How the evils of this were to be avoided he did not know, but it was to investigators such as those associated with the Institute that Parliament might look for guidance.

#### Future Prospects

Dr. DENIS CARROLL, director of the Psychopathic Clinic, followed with a brief statement on future prospects. There was a popular notion, he said, that the National Health Service Act and the Criminal Justice Bill would solve all their problems. Yet the situation was difficult. Under the Criminal Justice Bill many of the arrangements with magistrates which they in the Institute had brought about would receive legal sanction. But it was not known at present whether the clinic would or would not be transferred to the National Health Service. It was possible that the clinic would pass under the management of the appropriate regional hospital board and management committee, and likely, though not a foregone conclusion, that it would have representation on the managing authority. But at present they were in a position of uncertainty, and it could not be said whether approaching developments would make the work of the clinic easier or more difficult.

The meeting passed a resolution urging an approach by the Council to the Home Secretary and the Minister of Education for help for the Institute, and also to the county councils of

London and adjoining counties and certain boroughs with a view to obtaining an annual capital grant. The accounts, which were passed by the meeting, showed an excess of expenditure over income for the year of £1,188.

#### MEDICAL CARE OF THE AGED

At a meeting of the Liverpool Medical Institution on Nov. 13, with the president, Dr. H. WALLACE-JONES, in the chair, Dr. ROBERT KISUR opened a discussion on "Old People and their Medical Care."

Dr. Kemp spoke of the medical welfare of elderly patients in the Belmont Road Hospital, Liverpool, and in the Kirkdale Homes. The hospital cared for about a thousand sick old people and the homes for about the same number who were ambulant. Another thousand were looked after, according to the recent Merseyside Survey, in smaller religious or voluntary homes. Though this represented only about 3% of the old people in the district the majority of them could have been looked after at home but for the fact that they were single, widowed, or living apart from their families. Austerity was forcing many old people into institutions where hitherto they had often been medically neglected. The aim of a good medical service was to prevent people becoming bedfast and to get them back on their feet after an illness. The "bottle-neck" in bettering medical care was the numbers, training, and morale of those nursing the aged. They must be shown that their work could be worth while and well rewarded. Two "psychological brakes" were the apathy and hopelessness of the elderly themselves and the inertia of those who had previously been looking after them.

Dr. H. FERN stressed the magnitude of the task of caring medically for the aged, and enumerated the physiological changes that accompany senescence. He then discussed diagnostic pitfalls in the illnesses of old age. Students and young doctors needed better training in the technique of looking after old people. There was no need for the creation of a new specialty so far as old people were concerned. A hospital for old people only might be a gloomy place because of the high mortality among in-patients.

Dr. BASH MURRAY presented a retrospect of the history of medicine on this subject from the Egyptian era to medieval times before describing some of his own cases. One case was that of an epileptic, aged 74, who in an attack stashed his heart, which was sutured. After recovery he was operated on by Dr. Alexander, about 1905, and clearance of an old depressed fracture of the skull led to cessation of the epileptic attacks. The patient was alive at the age of 84 years.

#### Discussion

In the discussion which followed, Dr. ROBERT EVANS said that many old people admitted to hospital were suffering from two or more diseases, one of which was chronic, possibly of great medical interest but not causing symptoms, and a second acute but medically trivial disease like an enteritis or bronchitis. The cure of the second condition often enabled the patient to carry on his normal life despite the chronic disease. Deficiency diseases, including avitaminoses, were commonly part of a general malnutrition, often because of lack of either natural or artificial teeth, and this required the provision, in institutions for old people, of a diet which should be satisfactory nutritionally but require no chewing. Mr. COSBIE ROSS emphasized the great danger of immobilization in old age, and described the measures necessary to combat, especially, post-operative pulmonary embolism. These measures included an anaesthetic which would allow early recovery of consciousness; early post-operative exercises; raising the foot of the bed for forty-eight hours; and encouraging the patient to get out of bed soon after operation. For example, it was quite possible for a patient to sit out of bed four days after a retropubic prostatectomy. Contrary to the usual teaching, he had found local analgesia suitable for aged patients, especially in cases of strangulated hernia.

Dr. ROBERT W. KENNON said that the treatment of old people should be according to their physical age rather than their age in years.

## Correspondence

### Food Cuts and Calories

SIR.—On Oct. 23, 1947, Sir Stafford Cripps made the statement that, in view of the cuts in foods which he announced, the calorie value of our diet would fall to "just below 2,700 per day." Prior to that time it was claimed that our intake was 2,870 calories per day. Following the introduction of potato rationing, the Minister of Food stated that this step would reduce our calorie intake by about 70 per day. From these statements we might deduce that we now obtain somewhat above 2,600 calories per day. In view of these statements it was felt that a critical examination of the nutrient value of our diet should yield informative data concerning our actual intakes. This has been done and the figures are presented in the accompanying tables.

TABLE I.—*Rationed Foods*

	Amount per Week oz.	Calories	Protein g.	Fat g.	Calcium mg.	Iron mg.
Meat .. ..	14	1,000	56	84	42	14.0
Bacon .. ..	1	110	3	12	3	0.3
Cheese .. ..	2	234	14.2	19.6	460	0.4
Milk .. ..	40	680	36	40	1,360	0.0
Eggs .. ..	1	36	3	2.8	13	0.6
Butter .. ..	6	1,290	0	144	10	0.0
Margarine ..	1	253	0	28.1	0	0
Cooking fat ..	8	864	0	0	0	0
Sugar .. ..	4	284	0.4	0	0	0
Jam .. ..	63	4,473	151.2	18.9	1,008	31.5
Bread .. ..	48	768	19.2	0	96	4.8
Potatoes .. ..						
Total per week ..		9,992	283.0	349.4	2,992	51.6
Total per day ..		1,427	40.4	49.9	427	7.4

TABLE II.—*Selection of Points Goods per Month*

Points	Amount	Calories	Protein g.	Fat g.	Calcium mg.	Iron mg.
6 Biscuits ..	8 oz. plain	1,936	43.2	61.6	288	7.2
6 Cheese ..	8 oz. sweet	896	56.8	70.4	1,224	1.0
4 Canned fish (her- rings) ..	8 oz.	440	48.0	27.2	224	3.2
4 Dried fruit (apri- cots) ..	8 oz.	400	11.2	0.0	208	9.6
2 Macaroni ..	16 oz.	1,536	48	9.6	102	6.4
2 Cereals ..	8 oz.	776	28	5.6	56	9.6
4 Dried potatoes ..	16 oz.	1,650	45.4	0.0	288	8.0
Total month ..		7,634	290.6	174.4	2,390	45.0
Total day .. ..		254	9.7	5.8	79	1.5

TABLE III.—*Personal Points per Week*

	Amount	Calories	Protein g.	Fat g.	Calcium mg.	Iron mg.
Chow mein (plain) ..	4 oz.	592	5.2	36.8	28	3.6
Pork .. ..		84.5	0.75	5.25	4	0.5

TABLE IV.—*Non-rationed Foods: Nutrients Available per Head per Day*

	Calories	Protein g.	Fat g.	Calcium mg.	Iron mg.
Vegetables ..	33	2.8	0.6	9	0.6
Tomatoes and citrus fruit	7	0.3	0	6	0.1
Other fruit ..	40	0.4	0	11	0.4
Leafy green veg ..	21	1.7	0	44	0.8
Other veg. (etc. potatoes)	9	0.4	0	19	0.2
Poultry, game and fish	40	6.2	1.6	20	0.5
Total per day ..	150	11.8	2.2	109	2.6

TABLE V.—*Totals of Nutrients Available per Head per Day*

	Calories	Protein g.	Fat g.	Calcium mg.	Iron mg.
Rations ..	1,427	40.4	49.9	427	7.4
Points goods ..	254	9.7	5.8	79	1.5
Personal points ..	84	0.7	5.2	4	0.5
Unrationed foods ..	150	11.8	2.2	109	2.6
Total ..	1,915	62.6*	63.1	619	12.0

\* First-class protein, 26.5 g.

These figures are calculated from the foods actually available by using the tables of "Nutritive Values of Wartime Foods" (Med. Res. Cncl. War Memorandum No. 14, H.M.S.O., 1945). The figures for bread presuppose that the full ration is taken in this form, but the figures are not significantly affected by taking a mixture of bread, flour, and flour products to the same B.U. value. The points goods have been selected to give as high a calorie and protein content as possible. Many actual selections fall short of these figures. The data for unrationed foods available are taken from the "Third Report on Food Consumption Levels" of the Special Joint Committee of the Combined Food Board, 1946.

It will be seen that these data give a daily calorie intake of 1,915. This value falls far short of the 3,000 calories which is recommended as the intake per day for a moderately active man and even short of the 2,500 calories for a moderately active woman. It would be interesting to know how the Ministry of Food arrive at the figure they quote. One can only assume that they calculate their data from the total amount of food available for civilian consumption without taking into consideration wastage (a) involved in storage, transport, and the breaking down of large bulk to small; (b) caused by storage in shops and during serving; (c) involved in preparation and cooking and on the plate. Much of this waste is inevitable, and to disregard it is to present a completely distorted picture.

From where are we to obtain, therefore, the differences between these calculated figures and the actual requirements? For many people canteens are not available, and a restaurant meal will not supply more than 300-400 calories and 5 g. of protein. In addition a large number of people are not able to obtain or afford even one restaurant meal per day. It would be interesting to know what answers the Ministry of Food can offer to these points.—I am, etc.,

Biochemistry Dept.,  
St. Thomas's Hospital Medical School, S.E.1.

G. T. MILLS.

### Diet and the Nation's Health

SIR.—It is with surprise that I read press reports of a discussion which took place at a recent meeting of the Hunterian Society and of the motion carried that "Our Present Diet is Undermining the Health of the Nation." In my opinion the reasons given by the speakers for the motion were not based on scientific and practical experiences. May I quote some of my own observations as an obstetrician. A comparison carried out at the Maternity Hospital of the University of Berlin showed that the average weight of 3,000 babies born in 1911-12-13 was 6 g. less than that of the equal number of babies born in 1919-20-21—i.e., during a period of actual famine bordering on starvation in Germany. The maternal morbidity and mortality rates were appreciably lower during the latter period; in fact, for several years we were unable to show our students a single case of eclampsia, and this in two hospitals with 3,000 to 4,000 maternity cases per annum.

What became of the babies born during the hunger years? Well, 20 to 21 years later they formed the backbone of Hitler's crack divisions which overran half of Europe and North Africa—and even then after several years of sharp food-rationing dominated by the slogan "Guns before Butter." In Russia following the 1917 revolution there was widespread starvation, but the babies born during that period became the defenders of Moscow and Stalingrad and the conquerors of Berlin.

I myself had to feed on a diet far inferior to that of the poorest Englishman of to-day, consisting almost entirely of black bread made up by potato peels, sawdust and turnips, artificial honey made from turnips and vegetables—again mostly turnips—no sugar or sweets, no milk, hardly any fats or proteins. But even so in 1921 I was in the winning boat against such countries as Sweden and Switzerland; my children born in 1922 and 1923 twenty years later passed their medical examinations for the R.A.F. and the W.A.A.F. as A1. And remember, thirty years or so ago we did not possess our present knowledge of the importance of vitamins and protective foods.

May I be permitted to add that I consider the arguments for the motion as unfounded and even frivolous. The motion carried by the Hunterian Society may well help to undermine the morale of the nation if unscrupulously exploited.—I am, etc.,

London, W.1.

STEPHEN K. WESTMAN.

## Duodenal Ulcer and Priority Foods

SIR, I was interested in Dr. A. H. Morley's letter on duodenal ulcer and priority foods (Nov. 8, p. 748) and would say a word on the other side of the picture. It is agreed, of course, that many duodenal ulcers are cured, temporarily or otherwise, or lie dormant for long periods, but surely it is also agreed that the only rational way to treat an ulcer subject is to keep him well, and that a bland diet, especially with regard to the protein intake, is a very important factor, if not an essential one, to that end. He is advised, and rightly, I believe, to avoid tough meat, stew, cheese, orange, salt and spicy foods, yet the bulk of his rationed food will come fairly under these categories. He does better on white fish, but that is sometimes short, often of poor quality, and can be extremely monotonous. I am informed that an extended course of this can destroy the appetite and undermine the character, that an addict is liable periodically to break out into homicide, divorce, or a delirium of liver and onion, corned beef, tuppens, or other flavoursome but decidedly connoisseurs.

No doubt there are some who may not require these priority foods, but I am of opinion that any general curtailment of these would result in an increase, and probably a large one, in the incidence of ulcer breakdown. It is well to remember that such a breakdown may be regarded in these days as a small national disaster. Ambulatory treatment is seldom satisfactory, and the subject, to have any real prospect of cure, must lie up for weeks or months in the care of others at home or in our hard-pressed hospitals.

I feel exception should be taken to Dr. Morley's statement that duodenal ulcer "has, indeed, become a somewhat popular malady—and no wonder!" If this means anything, it implies an unfortunate innuendo. Surely the patient does not elect to have an ulcer—the diagnosis is with the physician. Any claim by an unknown patient can be readily checked as a rule. I have not found that ulcer patients consider themselves fortunate. Dr. Morley's estimation that this priority milk would float a battleship may be accurate, but surely this alternative need not be considered at the present time. Our old friend Chad has just peeped over my pile of milk certificates with a startled comment on our naval establishment.—I am, etc.,

S. STUART

J. CRAWFORD

SIR,—It must surely cause some astonishment that there are medical men who hold the view expressed by Dr. R. Stuart (Nov. 22, p. 842) that "the symptoms of chronic duodenal ulcer are chronic, recurring at regular intervals every day and every night throughout many years." Can he have in mind some atypical condition such as an ulcer extending to and constricting the pylorus? It is, after all, the alternating bouts and the much longer intervals of freedom from symptoms which constitute so invaluable a diagnostic feature of the disease. In this connexion I would quote Sir Robert Hutchison, when he says in his *Lectures on Dyspepsia* (1927, London): "The History is in many cases perfectly clear and sufficient alone to base a diagnosis upon. It is as follows: The patient will tell you that, often for years back, he has been subject to attacks of indigestion which have been intermittent, that is they have cleared up and he has been well between them." And again, to quote Sir James Walton in his *Surgical Dyspepsias* (1930, London): "When once the disease is well established one of its most characteristic features is the periodicity of the symptoms. This is more marked than is the case with gastric ulcers, and indeed than in any other disease. There will be attacks of acute symptoms persisting for some three or four weeks, which are followed by periods of complete freedom. These periods will nearly always last for some months and may persist for nearly a year."

In regard to the other point in Dr. Stuart's letter, although it may be conceded at once that regulation of the patient's habits—frequent small regular meals, avoidance of irritants and tobacco, worry and fatigue, and so forth—is of great importance in prolonging the periods of freedom from symptoms, a rigid regime of diet is considered by many authorities to be unnecessary. Dr. A. H. Douthwaite (July 12, p. 43) expressed this view.

This brings me to my original contention, to which I adhere, that to lavish 10 pints (5.7 l.) of milk a week (five times the

allowance for the ordinary consumer at present) and priority in eggs on the chronic duodenal ulcers is indeed squandering an expressive word, for which I thank Dr. Stuart. It fits admirably.—I am, etc.,

London, N.W.7.

A. H. MORLEY.

## Vitamin-D Requirements in Pregnancy

SIR, Dr. I. J. Harris is to be congratulated on his admirable survey (Nov. 1, p. 681) of the present state of our knowledge as to vitamins. I venture, however, to question the accuracy of one of his statements: "For nursing and expectant mothers 1,000-2,000 i.u. (vitamin D) daily may be prescribed. . . ." I made a search of the literature on this subject about a year ago; I found only vague and contradictory statements. The following two quotations from recent authoritative textbooks are typical: McCune<sup>1</sup> states that during pregnancy "an amount of vitamin D equal to that contained in 5 teaspoonfuls of cod-liver oil—that is, 1,700 i.u.—may be required in addition to a high calcium intake to prevent a negative balance and guarantee calcium retention." Shohl<sup>2</sup> writes: "400 units of vitamin D and 1 quart of milk daily should be included in the diet of pregnant women." No experimental evidence is brought forward in support of either of these statements.

I have recently completed a four-year survey of normal pregnancy in the out-patient department of the City of London Maternity Hospital. Some of the biochemical findings have been published.<sup>3</sup> They cover 226 48-hour calcium and phosphorus balances at various stages of pregnancy. They would seem to show that doses of vitamin D smaller than 10,000 i.u. per day have no influence whatever on calcium and phosphorus metabolism and that doses considerably larger than this (up to 36,000 units per day) exert a definite influence only if the calcium intake is above 1.5 g. per day in the early months and later 2 g.

This subject is a difficult and complex one. My findings, to be conclusive, must be confirmed on a larger number of cases. But this is not a matter of purely academic interest. It concerns us all—vitality. Until further experimental evidence, adequate and incontrovertible, is made available, I submit that we should play for safety. In a climate like that of England every pregnant woman should be given a supplement of vitamin D in doses of not less than 10,000 i.u. per day in the first 7 months, and 20,000 i.u. during the 8th and 9th months.—I am, etc.,

Como, Italy

## H.T.S.T. Pasteurization

SIR,—As far as we are aware no report has been made of the efficiency of the H.T.S.T. method of pasteurizing milk on a commercial scale. The results of tests carried out by Dr. Porteous of St. Mary's Hospital on samples taken from three of our plants using this process therefore may be of interest outside our own organization.

One hundred and twenty-nine samples of the raw milk used gave a positive guinea-pig test for tubercle bacilli. The 129 samples of commercially pasteurized milk corresponding to the above raw were all negative in the test. All these pasteurized milk samples also passed the official phosphatase test.

The samples covered a period of two years from January, 1945, to January, 1947.—I am, etc.,

## Thiouracil

SIR,—It is with great interest that I have read the review by Dr. H. Cookson and Dr. F. H. Staines (Nov. 15, p. 759) on their experience with thiouracil. With increasing experience in thiouracil therapy it is evident that the risk of immediate toxic effects is diminishing. I note, however, that the length of treatment is given as "a year or two and may be even more." That this chronic therapy with a drug which poisons the thyroid is not altogether without risk of far more serious consequences is shown by the work of Purves and Griesbach,<sup>1</sup> who produced

thyroid adenocarcinoma in almost 50% of rats to whom they administered thiourea for more than two years.

The histological picture of the human thyroid after thiouracil therapy shows marked cellular activity, and before its general use is recommended further research should be carried out on the possibility of delayed after-effects. The experienced surgeon who resects a toxic goitre knows that 99% of his patients should survive the operation, that about 90% will lead approximately normal lives without special supervision, and that, in the event of an error in diagnosis, malignancy will be revealed and can be treated without further delay. The thiouracil drugs are most valuable in preparing a patient for operative treatment, but caution is advised before suggesting that they should replace it.—I am, etc.,

London, N.2.

HENRI ROUALLE.

### Measles Prophylactic

SIR,—Following your leading article (Nov. 8, p. 737) on the use of gamma globulin as a measles prophylactic it would seem worth while to stress once again the value of a dose of adult whole blood intramuscularly if given at any time up to the sixth or seventh day of incubation. Gamma globulin is expensive to produce and uses the time of highly skilled technicians. Blood, 4 to 10 ml. according to the child's age, taken from the mother and injected immediately, is cheap and speedy therapy. The marked difference in the severity of symptoms in the unprotected case and the partially protected contact is so constant that the method can be advocated as a routine measure when the first of a family of children is found to have measles or other contacts are known.—I am, etc.,

Stanmore, Middlesex.

HARWOOD STEVENSON.

### Dicoumarol

SIR,—I read with interest your annotation (Oct. 25, p. 662) on dicoumarol and subsequent letters. I feel that Dr. Frank Marsh (Nov. 8, p. 748) is on the right lines when he suggests a large dose for the first two days, then an interval, and subsequent smaller doses.

My experience with Quick's method of prothrombin estimation has been singularly unfortunate. The results I obtained were far too varied to permit of any serious consideration. We used the clotting time and attempted to double the original figure. This was done throughout by Lee and White's method. In a number of cases alarming features resulted before the clotting time had doubled. Obviously the drug has a cumulative effect, and the clotting time does not begin to rise appreciably until the patient has been on it for some time, and then it rises with marked rapidity.

I would suggest that the drug be given in maximal doses—i.e., 300 mg. the first day, 200 mg. the second day, then 150 mg. daily until the clotting time begins to rise, and at that stage withheld. When the clotting time has returned to its original value dicoumarol should be given again. We used fresh-blood transfusion to lower the clotting time and found that it works fairly rapidly. There is at least a 48-hours latent period before intravenous vitamin K begins to show its effect.—I am, etc.,

Birmingham

M. J. PIVAWER.

### Yeast Extracts and Fat Absorption in Sprue

SIR—For a detailed discussion of the points raised by Dr. K. D. Keele (Nov. 15, p. 794) we would refer those interested to our paper in the current issue of the *Quart. J. Med.* (1947, 16, 99). In that paper the evidence for the effectiveness of yeast extract is given, and due acknowledgment for statistical help is made to Mr. Dilwali (not Mr. Dilwater). As Dr. Keele rightly points out, we were not in clinical charge of the patients in Portsmouth and so we have relied mainly on biochemical evidence for the effect of yeast extract; nor were we in a position to "offer the issue" at that time by the use of yeast extract alone. However, we have since treated patients with sprue in this country and have been able to maintain them in clinical remission by yeast extract without any liver therapy.—We are, etc.,

D. A. K. BLACK.

L. P. R. FOURMAN.

### Status Epilepticus after E.C.T.

SIR,—Dr. A. Folkson's memorandum on a case of status epilepticus precipitated by E.C.T. (Aug. 30, p. 335) prompts me to record a similar case.

In September, 1944, an African woman of the Yao tribe (who live on the borders of Tanganyika and Portuguese East Africa) was admitted to this hospital. She was about 45 years of age. The certificate stated that she wandered aimlessly among her neighbours, that she slept in the bush, and that she thought people were going to kill her. After admission she was either indifferent and preoccupied or nonsensically loquacious. She had corneal opacities and septic teeth. The spleen was enlarged, but there were no malarial parasites in the blood. There were no neurological signs or history of epilepsy. The blood Kahn was negative and the C.S.F. W.R. was negative, with no increase of cells or protein. Attention to her general health produced a partial improvement. On Feb. 20, 1945, she was tried with E.C.T. at 10 a.m. (105 volts, 0.4 sec., 160 milliamp.-sec.). There was a delay of 3 or 4 sec. The next day at 3 p.m. she suddenly passed into typical status epilepticus. At 3.45 p.m. she was given 1/2 oz. (14 ml.) paraldehyde in olive oil per rectum. The fits began to lessen in a few minutes and had ceased after 1/4 hour. There has been no recurrence to date.

—I am, etc.,

Dodoma, E. Africa.

E. J. FOLEY.

### Routine Serological Tests for Syphilis

SIR,—At a recent conference of doctors in America surprise was expressed that in this country serological tests for syphilis were not routinely carried out by law on such occasions as marriage, at life insurance examination, or on entry into the Services as is current practice in the States. It was furthermore stated that representatives of this country had indicated that such a proposal would lead to public outcry and would never be permitted, and in any case such a course was unnecessary, because the incidence of venereal disease is so much lower in this country than in the States.

Surely in these enlightened days such a position is indefensible? If we have no serological tests, what reason have we for saying that our incidence is low? Clinical manifestations of the disease are no guide, because they may be dormant for many years and thus be undetected. Is it national prudery, smug hypocrisy, or a fear of exposition which leads us to adopt this rather dubious delicacy on such a matter? I am not a syphilologist, but doubtless there are many with greater knowledge in the matter who can give the answer to this apparent diagnostic obscurantism, and whose views I should like to hear.—I am, etc.,

Bristol,

K. G. BERGIN.

### Penile Carcinoma

SIR,—The incidence of cancer of the cervix in Jewish women is relatively low, and this has frequently been ascribed to the observance of laws which combine common-sense hygiene with religion. Mr. W. Sampson Handley (Nov. 22, p. 841) brings forward evidence which suggests that it is the routine circumcision in the male which is the operative factor. If the "transference to the vagina of the mixed bacterial flora that flourish beneath the prepuce" ultimately, by means of chronic infection, leads to cancer of the cervix, then there must be many more cases in which, even without cancerous changes, it results in discomfort and chronic invalidism. Having built up a strong case and drawn the correct inference, your correspondent advises routine preputiotomy in male infants because "it is unlikely that the routine circumcision of male infants would commend itself to English opinion."

What are the objections to routine circumcision and how does preputiotomy meet them? Does the main obstacle to the former lie in the lack of knowledge of a simple operation or in the psychological objection to imitating the Jews? It seems to me that your correspondent's compromise is a bad one. It is true that circumcision, as generally taught, involves general anaesthesia, pressure forceps, scissors, and sutures, while slitting up the prepuce "in the first few days of life can be done without an anaesthetic." Although reference is made to "an experiment conducted on a national scale for two thousand years" (the estimate is a conservative one), there is no mention of the technique which has made it possible. In fact few, if any,

surgical textbooks mention it, and one can only wonder at the apathy of our surgical colleagues. Imagine the consternation that would be caused at the Final Fellowship examination by the question, "Describe the technique of circumcision as practised by the Jews."

"Ritual" circumcision takes about two seconds, and apart from a shield and scalpel does not involve the use of scissors, forceps of any kind, sutures, or general anaesthesia. Nobody can deny that the results are excellent in every way. Preputiectomy would take almost twice as long, on the average, and the introduction of scissors points they would frequently have to be clipped once is not without potential danger to the meatus. The final result can only be described as aesthetically and cosmetically deplorable. Were it practised on a national scale there would soon be a revolution of feeling on the part of public opinion and the incidence of cancer of the penis and cervix would rise to even greater heights. Your correspondent asks us to face the facts but has only produced half-hearted proposals to meet them.—I am, etc.

LESLIE WILKINSON

DANIEL PRINCE

### Chemical Carcinogenesis

SIR.—As you point out in your leading article (Oct. 25, p. 19), chemical causes of cancer are so numerous that specific attention is not confined to any one of them. It is perhaps worth noting that they all cause damage to a group of cells, with stagnation of circulation, which must be maintained for months. Locally devitalised cells, with local stagnation, are quite characteristic of cancer. As the aetiology and the disease seem to arise from the same conditions, the origin must be intracellular, and there is little doubt that local stagnation is a dominant cause.—I am, etc.

MURRAY

RICHARD KEEFE

### Tapered Sutures for Vascular Surgery

SIR.—A successful issue after such operations as those for coarctation of the aorta, congenital pulmonary stenosis, etc., depends chiefly on the establishment of a water-tight, or rather blood-tight, anastomosis of the blood vessels concerned. Accurate apposition with no tension is essential if leakage is to be prevented, and this can generally be attained; but there is another snag—leakage from the needle holes—and I know of several disasters from this "complication." In these cases an atraumatic (eyeless) needle with non-capillary suture material was used with the obvious result that the suture did not completely dam the holes made by the needle of larger calibre. I put forward the suggestion, which may have been made before, that the suture material should not only be absorptive but that it should be tapered. Only the first few inches need be tapered, and experiment will easily prove the exact gradation of tapering necessary to adequately dam the holes made in the vessel wall by the needle. Most good fishing lines (made of silk) are tapered: there should be no difficulty in procuring tapered suture material.—I am, etc.

F. R. BROWN

### Synchronous Combined Total Gastrectomy

SIR.—I have read the article by Messrs. J. Basil Hume and Guy Blackburn (Nov. 22, p. 817) with great interest and feel that they deserve congratulations on their ingenuity in approaching this problem. While it is an asset of the method that the question of operability can be decided on abdominal exploration, there are a number of points I would venture to criticize. I cannot agree that the division of the thoracic arch in the combined abdominal and thoracic incision "is undesirable for the patient's convalescence." When, in the abdomino-thoracic approach, the costal arch and diaphragm are divided, the ribs can be retracted with minimal pressure and therefore minimal trauma and shock; again, the arch can be firmly reconstituted at the close of operation by a single suture through the cartilages. The resection of a rib appears to me a more serious problem for the patient.

Are they not too generous in their time allowance? A single surgeon, using the abdomino-thoracic method, can easily do an uncomplicated case inside two and a half hours. I certainly do

not consider that "excision of the cardia and 2-3 cm. of the oesophagus is essential if ablation of a growth is to be radical." Some 80% of gastric carcinomas begin in the prepyloric region and only in the late stages involve the glands on the left of the cardia, while the glands on the right are removed in the standard partial gastrectomy for carcinoma. It is the spread to the coeliac axis and porta-hepatic glands that decides the issue as regards plandular involvement in late cases. For this reason alone total gastrectomy is unlikely to give late results better than partial gastrectomy in the case of carcinoma arising in the common site. Its best role is for linitis plastica, growths of the fundus and cardia, and as a palliative for certain late carcinomas. Finally, is the Roux or any type of entero-anastomosis really necessary in total gastrectomy? I have not found it so in a small number of total and a fairly large number of high partial gastrectomies.—I am, etc.

T. O'NEILL

### Anticoagulants in Coronary Thrombosis

SIR.—Prof. A. A. Fitzgerald Peel mentions my name in his letter in the *Journal* of Nov. 15 (p. 794). He does not seem to have used heparin in the cases he cites—the drug that produced such a remarkable recovery in Prof. Lambert Rogers's case of pulmonary thrombosis. Whether heparin offers any advantage over dicoumarol I do not know. It will be observed that Prof. Peel's first two cases had each more than one lung infarct before treatment was started. Two cases with hypertensive heart failure and lung infarct were given dicoumarol and developed further lung infarcts. His fifth case with hypertension and angina of effort, after treatment with thiocyanate and the blood pressure dropping from 220/110 to 180/94, developed a severe attack of coronary thrombosis.

I respectfully submit that Prof. Peel's cases are rather complicated to dogmatize about the action of heparin or any other anticoagulant in coronary thrombosis in its initial stage. Prof. Peel has, however, established in his letter "that the blood coagulability is not the only factor which influences the extension of a coronary thrombosis." In my judgment the two essential factors in producing coronary thrombosis are degenerated arteries in the heart and low blood pressure, which will favour the formation of a thrombus.

Coronary thrombosis usually occurs when the patient is quiet and often in bed, when the circulation is quiet and perhaps slow. In my letter of Nov. 1, I pointed out that it was the underlying cause—arteriosclerosis—that required treatment. A suitable regimen would be one in which flesh foods are reduced to a minimum, with plenty of fruits, vegetables, etc. From years of observation I have found the prolonged use of iodide of potash is the only drug I know that will arrest atheroma of the arteries and largely restore them. But the drug has to be given at least three months before decided changes can be observed from the improvement of the patient. Dr. Lander Brunton expressed a similar opinion on this action of iodide of potash in his book on the action of drugs.—I am, etc.

Glasgow

J. T. MACLACHLAN

### The Extent of Neurosis

SIR.—One cannot but express sympathetic agreement with Dr. Willoughby Clark's plea (Nov. 8, p. 746) that more time should be devoted to those suffering from functional illness. Nevertheless, his suggestion that two afternoons per week could be set aside for such patients—each presumably to be subjected to an hour's psychiatric probing—is for the average busy practitioner a sheer impossibility. This would entail the sacrificing of one's hard-earned half-day (often no half-day at all) and Sunday afternoon to this, albeit worthy, purpose. Admittedly the neurotic forms a certain proportion of the normal surgery "clientele," though I disagree with Dr. Clark's estimate that from one-third to two-thirds are in this category. It is considerably lower than that—I would place it at perhaps 15% to 20%. Many of these people have very mild functional derangements, which the much maligned pill and bottle of medicine go far to eradicate, combined as they are with the sympathetic advice of an experienced practitioner, who can find out quite a lot about his patients' problems in considerably less time than

the regular weekly hour advocated by your correspondent. Incidentally I have yet to meet a psychiatrist who did not prescribe phenobarbitone in some form for his cases.

Needless to say the more severe forms of functional disability should be referred to an expert, though in many industrial areas psychiatrists are in very short supply. One can only hope that more psychiatric clinics will be set up in the near future. All this and more will no doubt be provided in Mr. Bevan's nationalized Utopia, which we are assured is just around the corner. Meanwhile the general practitioner will continue to give of his best to the neurotic patient. But ten hours a week! No, Sir! It just cannot be done.—I am, etc.,

Blackburn.

T. J. BURKE.

SIR,—Was there so little neurosis in the Victorian era? I remember it was an axiom in Edwardian times that nervous disorders were rare among the working classes, and it was not till good King George's days that this idea began to be undermined. The 1914-18 war damaged it badly. Since then social workers have told me nervous disorders were frequent in all three eras, especially among women of the depressed classes.

Why did we meet them so seldom in hospital? First, I think, because the sufferers had no suitable vocabulary. Pain, sickness, wasting, even our old friend "a nasty 'ackin' cough," were recognized respectable symptoms. Forty or fifty years ago, what sort of shrift would depression, fatigue, and anxiety have received at "out-patients"; and, to arrive at our second reason, what sort of treatment?

It seems strange so little is known of the distribution and occurrence of the nervous disorders. In his book *The Spirit of Discipline*, Dr. Francis Paget has an interesting passage on accidie: "Homeless and solitary hermits are especially assailed by it, and monks find it most troublesome about twelve o'clock, so that some . . . have held it to be 'the sickness that destroyeth at noon-day.'" Dostoevsky notes the frequency of nervous disorders among Russian peasant women. Oliver Wendell Holmes notes its frequency in New England, and quotes the seventeenth-century divine, Cotton Mather, on this subject: "New England, a country where Splenetic Maladies are prevailing and pernicious, perhaps above any other." In the seventeenth century at home has anyone noticed what a superb clinical picture Bunyan gives us of Mr. Fearing in the *Pilgrim's Progress*? Few men knew social life and conditions in the eighteenth century as John Wesley knew them, and he lived from 1703 to 1791. In one of his letters he refers to "Melancholia" as being so prevalent that it is known as the "Englishman's Disease."

Accidie, splenetic maladies, melancholia may have no determinate meaning. Neither has neurosis. Those who believe "nerves" to be a modern invention should look up Proverbs xviii, 14: "The spirit of a man will sustain his infirmity; but a broken spirit who can bear?"—I am, etc.,

Glasgow

IRENE N. CLOUGH.

### An Endotracheal Flange

SIR,—May I compliment Dr. John Gordon (Nov. 15, p. 785) on his design of a metal flange for use in endotracheal catheters under a face-piece? Those anaesthetists who are unable to obtain such a flange or a catheter with rubber flange incorporated, and do not wish to tear the end of the catheter with a safety-pin, may welcome the following suggestion. Pierce the catheter with the point of a red-hot safety-pin. The resultant holes will be permanent and will last the life of the catheter without splitting.—I am, etc.,

London, W 4

DONALD BLATCHLEY.

### Cats and Poliomyelitis

SIR, Dr F. L. King-Lewis's letter (Nov. 15, p. 795) tempts me to say that I had one case of poliomyelitis in a farmer who lived in an isolated farmhouse. In this farm there had been from time to time an epidemic in which the cats became paralysed and died immediately. This also may be coincidence.—I am, etc.,

Leitchfield, Herefs.

NORMAN MACFADYEN.

### Child-bearing and Tuberculosis

SIR,—I would like to join other contributors to your correspondence columns in congratulating Drs. C. J. Stewart and F. A. H. Simmonds on their paper (Nov. 8, p. 726) on the above subject. This carefully compiled review gives statistical confirmation to the results already published by myself in 1943 and 1946 and obtained in the special maternity unit for tuberculous women at Black Notley. When the unit was first opened in 1937 I approached the subject with scepticism, but over ten years' experience of treating a total of 260 patients, 75 of whom had active pulmonary tuberculosis on admission, has convinced me that it is difficult to justify termination of pregnancy on medical grounds alone.

Dr. P. Heffernan (Nov. 22, p. 837) refers to a temporary improvement which may occur in active cases during pregnancy, followed "in only too many cases" by an "acute flare-up" at the end of the puerperium. It does seem possible that physiological changes in metabolism during pregnancy may have some degree of beneficial effect, but much further research on this aspect is required, and until such an effect can be proved more than a clinical impression, or an arm-chair hypothesis, it should not enter into the practical management of tuberculous women. I must, however, again dispute the contention of Dr. Heffernan (and others) that pulmonary tuberculosis is particularly liable to "reactivate" or "flare-up" shortly after delivery. At any rate under the conditions available at Black Notley fewer cases break down after delivery than would be expected to occur within the same time in the natural course of the disease irrespective of pregnancy.

Apart from such inexorable progression of the disease, the real cause of those breakdowns that occur are due to such factors as the strain of caring for the infant, overwork, financial strain, etc. In other words, the cause of breakdown is social rather than medical, and if abortion is being considered for a phthisical woman we should recognize that the indications are indeed social and not the threat of harm resulting from pregnancy and labour *per se*. This of course raises important medico-legal questions, and Drs. Stewart and Simmonds's conclusion that its necessity must be established in each patient should be always in the forefront of our minds. Incidentally, the legend of a sudden fall of diaphragmatic level with delivery—and the alleged effects therefrom—still seems to worry many workers. Like Charles II, it is "an unconscionable time a-dying." Space will not permit me to enter into a dissertation on this particular aspect, but there is no doubt that the effect of diaphragmatic level has been very greatly exaggerated.—I am, etc.,

Black Notley, Essex.

RAYMOND C. COHEN.

SIR,—The article on the above subject by Drs. C. J. Stewart and F. A. H. Simmonds (Nov. 8, p. 726) has prompted me to write expressing my alarm at the ever increasing number of articles which have appeared recently on this subject, all endeavouring to prove that pregnancy has no effect on tuberculosis. It is not my intention to challenge their views and findings except to mention that tuberculosis runs such a variable course that it is almost impossible to provide reliable controls. The articles are misleading in that the natural inference drawn from them by anyone not in close contact with the domiciliary control of tuberculosis is that there is no justification for terminating pregnancy in a case of tuberculosis, whether active or not.

The present-day appalling overcrowding as a factor in the spread of tuberculosis is well known. The fate of young children in tuberculous households was investigated by the Lanes County Council in 1929, and this proved that the death rate in children under 5 from non-pulmonary tuberculosis (two-thirds of the deaths being from tuberculous meningitis) was approximately fourteen times greater in a household where there was open tuberculosis than in a normal one. Under present-day living conditions this would no doubt be appreciably higher.

The development or otherwise of lung changes is only one of many factors that have to be taken into account. There are others that from a practical point of view are of far greater importance. Correlated with these is the appalling failure of

## Towards MORE NORMAL CONTROL

Successful control of diabetes cannot be claimed unless the blood sugar is kept within safe limits and the patient's activities are interfered with as little as possible. One injection of Globin Insulin (with Zinc) before breakfast is no great inconvenience and can control the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the Ideal—the normal control of blood sugar.

**'WELLCOME' GLOBIN INSULIN (WITH ZINC)**

### COLLUMINA

Regd. Trade Mark

#### aluminium hydroxide preparations for effective antacid treatment

A highly active, acid-soluble aluminium hydroxide (otherwise known as hydrous oxide of aluminium) is the basis of all Collumina preparations.

##### POWDER

A new preparation available as an alternative to the suspension, Collumina Powder corresponds to the Dried Aluminium Hydroxide Gel (U.S.P. XIII). 1 gm. will neutralize 250 ml of N/10 HCl in one hour.

Bottles of 50 grm.

##### TABLETS

A new preparation. Each tablet contains 5 grains of aluminium hydroxide powder with suitable flavouring.

Bottles of 60 tablets.

##### SUSPENSION

The original preparation (known as Collumina and containing 5% to 6% of aluminium hydroxide in aqueous suspension, with suitable flavouring. 5 c.c. will neutralize 100 c.c. of N/10 HCl in 10 to 15 minutes.

Bottles of 8 fl. oz. and 40 fl. oz.

A new brochure on aluminium hydroxide therapy is available on request.

# The Successful Treatment of

## FIBROSITIS

and certain cases of

## RHEUMATISM

with

## NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism [Acute and Chronic], Muscular Pain [of Traumatic Origin]."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles:  $\frac{1}{2}\%$ , 1% and 2% Solutions.  
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.0002 gm. epinephrine and 0.0002 gm. capryl hydrocupreitolin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

PHARMACEUTICAL MANUFACTURING CO. LTD.

### A SUMMARY OF THE ADVANTAGES OF STREPH

- (1) Non-selective.
- (2) Activity is maintained in the presence of proteins.
- (3) Non-necrotic, non-toxic, non-staining.
- (4) Clear solutions with water, normal saline, and alcohol.
- (5) Powerful deodorant.
- (6) Almost odourless.
- (7) Powerful detergent and compatible with soap.
- (8) STREPH is approximately three times as effective as Liq. Chloroxyleneol or lysol.

For these reasons STREPH is the ideal antiseptic for medical, surgical and obstetrical use.

LONDON

so many patients to take even elementary precautions against the spreading of infection. The other extreme is the mother who is over-anxious about infecting her child, and one has known this constant worry to have caused deterioration of the mother's general health, followed by a flare-up of the old disease.

I have at present a patient who was confined shortly before her admission to sanatorium. Neighbours agreed to take the baby on the understanding that as soon as the mother completed treatment the baby was to be returned to her. On discharge the mother was still an open case. The fact that she now realizes that there is little hope of her becoming fit enough to take the child back (he is unwanted by his foster parents) is, in my opinion, largely responsible for her present rapid deterioration.

Prolonged ante- and post-partum institutional treatment is advocated, but how can this be carried out with the extreme staff and bed shortages now prevailing? Lack of domestic help, added financial strain, and sleepless nights all help to undermine the patient's already devitalized system. These factors, together with many others, need careful consideration before finally condemning abortion in tuberculosis cases. The pathological lung changes are of less interest to me than these other possible catastrophes. As an employee of a service whose motto is, "The Prevention, Treatment, and Abolition of Tuberculosis," I deplore this drive for babies without full regard to the consequences.—I am, etc.,

I. J. J. Jones, Carmarthen, Glamorgan.

J. T. JONES

### Foetal Cries

SIR.—In the provinces and other places where induction of premature labour is accorded a place in obstetric practice there must have been many thousands of inductions performed with the Drew-Smythe catheter since its description in the *Journal* in 1931. Yet apparently no case of a foetus crying following introduction of air into the uterus by this means has been recorded until 1947, when three cases occur within ten weeks.

The third case was in the Birmingham Maternity Hospital on Nov. 5, when one of the residents was attempting to induce premature labour at the 37th week for disproportion in a primiparida. The cervix was dilated digitally, and the Drew-Smythe catheter passed behind the presenting part to puncture the membranes rather lower than intended, about 2 in. (5 cm.) from the internal os. Only 5 oz. (140 ml.) of liquor escaped, and the uterus was compressed in an effort to drain some more. On releasing the uterus some air was sucked back along the catheter, and the foetus started to cry. The noise was easily heard by the patient, the doctor, the theatre sister, and the pupil midwife, all at the bedside, and it was audible from the far side of the labour theatre. I was called in to witness the phenomenon, and the child obligingly performed for about five minutes at irregular intervals, each period of crying representing some five expiratory efforts; the noise, as I heard it, was a combination of the gurgling of bubbles of gas in water and true vocal-cord vibrations. It could be heard from any part of the room and was particularly loud through the foetal stethoscope. Foetal movements were active throughout.

Three days later a repeat puncture was carried out, but no further foetal cry was heard, nor did the patient go into labour. Eventually labour was initiated by injections of "pitocin," and a live infant weighing 5 lb 3 oz. (3.1 kg.) was extracted by forceps on Nov. 16, eleven days after the first puncture.

In the cases described by Dr. E. Culphey (Sept. 27, p. 508) and Dr. Jean Burton-Brown (Oct. 25, p. 672) the induction was performed on multigravid patients a week before term, but this case clearly shows that a premature infant of less than 5-lb. (2.25-kg.) weight can be stimulated to respire in utero. It also demonstrates that the phenomenon is entirely without harmful effect to the baby. This might be anticipated, since it is obvious that the foetal air passages must normally be full of liquor, though the lung alveoli are collapsed; and it is well known to pathologists that a newborn infant can cry lustily at birth and still show complete pulmonary atelectasis at necropsy 24 hours later.

It follows that foetal respiratory movements must accompany the other foetal movements in pregnancy, especially when stimulated mechanically. These movements cause a flow of liquor amni to and fro across the larynx without either distending lung alveoli or producing cord vibrations. This fluid

is automatically expressed by the forces of normal labour, and the fact that some of it may have been replaced by air is of no significance to the infant's ultimate respiration. The high foetal mortality of previous reported cases has undoubtedly been due to interference.—I am, etc.,

Birmingham

W. G. MILLS.

### Vaginal Temperature

SIR.—Following Dr. M. Moore White's advice (Nov. 22, p. 841) I have read the article by H. W. Hales (*Medical Press and Circular*, 1946, 215, 310), which proved to be interesting, by no means beyond criticism, and entirely irrelevant to the subject matter of my letter (Oct. 25, p. 672), the burden of which was that basal temperatures taken orally give as much information in the study of cases of infertility as do those taken rectally or vaginally. It is quite beside the point that Hales has drawn attention to certain cases of chronic disease in which the rectal temperatures showed an elevation above the normal while the oral temperatures remained at or below the traditionally accepted normal level; and it is pertinent to remark that he does not mention the far more numerous cases of chronic disease in which this differential temperature effect is not manifested. If Dr. Moore White relies upon rectal temperatures in order to detect tuberculous endometritis it would seem probable that she is likely to miss cases; they certainly occur wherein neither oral nor rectal temperatures show any departure from the normal ovular pattern. A more reliable method, I submit, is the taking of routine endometrial biopsies.

Theoretical accuracy is not the sole criterion for choosing a particular clinical method; the patient's willing and continued co-operation is also worthy of consideration, and there is not the smallest doubt that few patients show any enthusiasm for taking rectal (or vaginal) temperatures for weeks on end, whereas most infertility patients will take oral temperatures with but little protest for as long as they are asked; and the important point is that oral temperatures are quite adequate for the detection of ovulation in a usefully large majority of patients.

The fact that Dr. Moore White's letter is immediately preceded by Mr. W. R. Forrester-Wood's report of a second patient having passed a thermometer into her bladder while endeavouring to take her vaginal temperature effectively answers Dr. Moore White's accusation that my condemnation of the method, because one woman had met with the mishap, was unreasonable. It also renders more than probable the previous occurrence of similar but unreported instances.—I am, etc.,

London, N.W.6.

G. I. M. SWYER.

### Student Health

SIR.—Attention to Mr. S. M. Drancz's letter on student health (Nov. 22, p. 843) is not without profit. I would suggest that in it are demonstrable some of the causes of our present position and direction. Inquiry will prove the adequacy and excellence of the medical services available to Edinburgh medical students and that the medical school has made provision for the services of an expert to study and report on student health. The proposal is made through the B.M.S.A. and support is sought of the N.S.U. and the Scottish Union of Students. These are all organizations which have grown up outside the Edinburgh Medical School. If there is necessity for local reform, demand properly should be made by that locality. Organization will grow to support policy. An Edinburgh student has no other responsibility than to his own medical school.

The proposal is that of the introduction of a compulsion; from which I would deduce that, first, the superfluity of the proposal locally punctuates the central origin of this policy. This is in accordance with Sir Ernest Graham-Little's observations about the colour of the B.M.S.A. We might do well to inquire into the real origins of that organization. Secondly, the chief effect in Edinburgh, therefore, would be the introduction of a compulsion. These observations are applicable to and germane to any centrally proposed measure. I must add that this is analysis of policy, not of one or more individuals.—I am, etc.,

Edin.

GEORGE H. BLAIR.

## Dimensions of Personality

SIR.—The review (Oct. 25, p. 657) by Dr. Eliot Slater of *Dimensions of Personality* by H. J. Eysenck, Ph.D., is surely calculated to send psychiatrists to a more than careful study of the book, especially as Dr. Slater ends with the striking, if also encouraging, assertion that "one consequence of this work will be that our text-books of psychiatry will have to be largely rewritten." It may be remarked at the same time that Prof. Aubrey Lewis, who contributes the foreword to the book, is much more cautious in his comments, and the author himself is far too modest to make any such claim. Dr. Eysenck, in fact, is disarmingly candid in the admissions he makes of the inconclusiveness of many of his experiments. The book deals with investigations and factor analyses based upon an "item-sheet" prepared for each patient admitted to Mill Hill Emergency Hospital. Two main factors emerged. The first of these the author calls, "neuroticism"; the second comprises two groups, the "hysteria-dysthymia" bipolarity.

Statistical method must of course have grist to work upon, and strictly speaking it doesn't matter to the statistician whether his data are true or false; he still can produce his tables of correlations. In the book in question Dr. Eysenck seems to have gone out of his way to suggest that his data may not be reliable. He refers, for example, to the "known inaccuracies of routine diagnosis and assessment" in criticizing some of Dr. Slater's own work on p. 56 and returns to the same theme on p. 190 and elsewhere. In this connexion one of Dr. Eysenck's experiments on the relationship between hysteria and suggestibility deserves special notice. A number of hysterics were selected and tested by experiment, and it was discovered that they are no more suggestible than other types of neurotics. It would seem to be of significance, although Dr. Eysenck does not mention it, to know whether, when the hysterics were diagnosed in the first place, the question of the existence or otherwise of suggestibility was considered as a diagnostic feature.

Dr. Eysenck frankly refers to the difference of opinion on the subject of factorial analysis, pointing out that some psychologists consider the factors to be statistical artifacts. He remarks also on the somewhat discouraging fact that already 350 factors have been discovered by statistical methods. In his work on suggestibility, which Dr. Slater especially picks out as convincing, Dr. Eysenck draws attention, in his usual impartial way, to two objections which might justly be raised against his experiments on the relationship of hysteria and suggestibility (p. 190). He describes two additional experiments which were devised "to obviate these two objections." In the end he is compelled, rather naively, to admit that these also "show comparatively little reliability" (p. 192).

Other criticisms could be made, but one which I think will appeal to those who can detach themselves from the statistical habit of mind is implicit in the description of Prof. Guilford's investigation by questionnaire responses of large numbers of students. His analysis failed entirely to disclose any general factor of "neuroticism" such as Dr. Eysenck has discovered (p. 38). But, by reanalysing the figures and using statistical procedures different from those of Prof. Guilford, Dr. Eysenck found that a general factor did appear which "in many ways resembles our general neuroticism factor" (p. 39). To the statistician this no doubt is a perfectly ordinary transaction. To others it may almost look like prestidigitation by the abacist, or the gentle art of having it both ways.

We have it on the authority of Jeans that God is a mathematician with, as Bertrand Russell has expressed it, a passion for doing sums. Psychologists will no doubt be stirred at the thought that by the aid of a new mathematical technique they are being brought, if only slightly, closer to the Creator. I cannot help thinking, however, that the exuberance of Dr. Slater's local or personal loyalty may have led him considerably to anticipate this devout consummation. The new advances described in Dr. Eysenck's book, if they are substantiated, it seems to me, are largely academic at present and have little practical application to psychiatry. The book is written mainly in the hypothetical and conditional key which seems to me to be right and proper in view of the stage of investigation that has been attained.—I am, etc.,

London W 1

FREDERICK DILLON.

## Hospital Treatment of School-children in Shropshire

SIR.—May I express the hope that Dr. H. W. Bambridge (Nov. 15, p. 795) will prepare his case very carefully before making a major issue of the arrangements for the hospital care of school-children in Shropshire? A county medical officer who wishes to bring more and more of our affairs under his control, either because he is genuinely concerned about some of our less successful results or because he believes that by so doing he is consolidating his position as a potential "führer" under the National Health Service, can be very convincing when dealing with a committee of laymen.

It is unfortunate but true that a great many photographs exist to show the appalling results of inept treatment of fractures in the bones of growing children. It is also true that statistics can be produced as to the need for a second tonsillectomy in children who have already been operated upon by general practitioners. (Which of us has not at one time or another heard a colleague say, "We don't do any surgery in the practice, just T.s and A.s and things like that"?) The occasional operator gets very useful results in routine surgery, but there can be few such who have not sometimes bitterly regretted that they had embarked on a seemingly simple task and found themselves most dangerously out of their depth. Errors of omission or commission can very easily be adduced in favour of any scheme to place the hospital treatment of school-children under the direct supervision of men or women of consultant status.

Let me stress that Dr. Bambridge can resent no more bitterly than I finding himself in a position in which he is allowed no latitude or discretion at all. It is infuriating to be told that any child who requires any sort of hospital treatment (which may merely be because an overworked mother cannot possibly nurse him at home) must be sent twenty-five miles to a hospital in a neighbouring county or forty-two miles if he is to remain in his own county, whether I can see any necessity for the move or not. I do feel, however, that there is a case, however specious some among us may consider it, to be answered and that our own cause can only suffer if we underestimate its plausibility in the eyes of the average layman.—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

## Planning and World Population

SIR.—With reference to the leading article (Aug. 9, p. 214) and the letter by Dr. G. Macdonald (Sept. 27, p. 506) on the same subject—viz., "Planning and World Population"—I should like, with your permission, to air a few views on the subject. In the first place let me say that I agree with both of you to a certain extent. Your leading article led me, when I read it, to exercise one of my hobbies, mathematics, by calculating how soon, with an average rate of reproduction such as my own personal family shows, the human race would become extinct. I worked it out at a period of about 775 years. Having made that calculation, I wondered how much the population of the world would increase to in the same time if every married pair produced one more instead of one less than they started from. I found that such average families of three would amount in 775 years to eight and three-quarter billion for the population of the earth—that is, English billions—whereas the present world population is approximately 2,000 million. Obviously there must be at work still forces of no mean order for the limitation of population, so that your fear of overpopulation at a very early date seems somewhat exaggerated.

You rightly rule out war and pestilence as agents for limiting population now, for it is the function of U.N.O. and medical men to counteract their pernicious influences respectively, however much we may doubt their effectiveness in that objective within any reasonably short time. Famine and limitation of birth rate remain. One of these must prevail, if the other fails to act.

I cannot follow your logic when you say that even with radical reorganization of land use and agrarian methods "an ignorant man with a hoe, his wife, and his children are a totally inadequate foundation for an enlightened state of society, a high standard of living, and elaborate social services. Much less is such a family a secure foundation for the production of food which can pay for the import of food from the few agricultural countries still possessed of an exportable surplus." Surely if the reorganization that you postulate were effected the primitive

conditions you depict in the words in inverted commas would disappear? Your argument is not sound.

Macdonald is right in thinking that your pessimistic attitude may do real harm. He quotes others to show that maximum production is still far from being attained from land in Africa, although he seems to feel sure that India, Java, Mauritius, and Jamaica can no longer be expected to improve their output. Baker and White say the population of South-east Central Africa is far below optimum. He rightly says that the population problem is one of balance. He says further that "the economy of grossly undeveloped countries can be improved more readily and more to the general advantage of the world by an increase in the supporting capacity of the land than by a restriction of population, though ultimately that must come." It must come when famine naturally follows unrestricted population increase, but it may come before that if the spirit of man is so broken by exploitation either by his fellow men or by an outraged Nature exploited by himself.

Another Baker tells how certain African tribes<sup>1</sup> deliberately set themselves to commit race suicide when their own foolish exploitation of their forest lands had made desert of fertile land. Their action was the wisest they knew to remedy their desperate plight. Life was not worth living, so they altruistically refused to pass it on to their offspring. Europeans are not so wise. They only *speak* of such action<sup>2</sup>; they *do* nothing about it. They do worse: they destroy what is of real value to keep up the price of the real in terms of the fictitious value—the mere token gold, and its even more fictitious substitute, paper money. They lend the fictitious money to those in need of real (food, clothing, etc.) produced by themselves. Their piling loan on debt and debt on loan to maintain the "gold standard" is no less absurd and complicated than the Ptolemaic astronomers' "piling cycle on epicycle, orb on orb" to maintain the geocentric theory of astronomy. The "balance" referred to by Macdonald is as great a simplification of present-day finance as was the Copernican astronomy a simplification of the Ptolemaic. One has only to equate the surplus products of each country to its needs from other countries to work out from these equations a unit of value that is indissolubly linked with the life of man on earth and so incapable of falling, in less than a generation, to less than half its previous value, as our old pound sterling has done. Even the smallest unit-value quantity of any of the necessities of life would be of more use to a millionaire in a desert than a bag of gold.—I am, etc.,

Durban, Natal.

#### Tuxford's Index

SIR.—In the paper "Calculation of Tuxford's Index by Graphical Methods" by Mr. H. Campbell (Nov. 22, p. 821) the formula used was that given by Tuxford in 1939, based on measurements made in 1909–10. Tuxford, however, revised this in 1942, basing the revision on the measurements taken in London in 1938. Tuxford (1939) in describing the index said that "the formulae being based on weight/height ratio have the defects of that ratio" and gives a number of illustrations of these defects—namely, for boys of different physique who would all be regarded as of normal development because of their equal weight/height ratios, for children stunted in early life by disease, and for obese children.

Mr. Campbell's statement that "the validity of the assumption [that the index does provide some basis for a comparison between different groups of children and between different stages of development among the same children] was tested extensively against clinical examination by Huws Jones (1938)" is open to question. Huws Jones took one single set of measurements of a number of children and compared the indices derived from these with the clinical assessments of the same children. He did not take measurements over a period of time as a measure of the different stages of development among the same children. While it is true that he found that of the formulae considered the Tuxford index gave the closest agreement with the clinical assessment, in the second part of this paper Huws Jones showed the unreliability of the clinical method. Moreover, Prof.

Bradford Hill made the cogent criticism that the clinician might, in his judgment of the nutritional grade, have been influenced by the physical measurements themselves. In any case Tuxford gives strong reasons against the "static" use of the index, seeming to prefer changes in it as measures of changes in nutritional state. Whether or not the formula is valid for that purpose has, as far as I know, not yet been proved.

Tuxford's index consists of two parts: (1) the anthropometric ratio weight/height, and (2) a refinement for age. The index does not therefore differ basically from weight/height—a formula which has been severely criticized as a measure of health or nutrition.—I am, etc.,

London, S.W.1.

#### Aneurin Deficiency

SIR.—I was delighted to read (Nov. 15, p. 763) that Dr. W. Russell Brain (formerly my respected teacher) uses an argument in relation to aneurin deficiency which I have used for 15 years in relation to bad teeth. Medical men often jib at recommending extraction of very bad teeth, because *some* have had extractions and not benefited. Does not this show that the extractions were delayed too long, allowing joints to be irreparably damaged, perhaps bone marrow badly injured with toxins, etc.? Surely it is better to extract early and benefit the patient than to allow auto-intoxication for the rest of natural life.—I am, etc.,

London, N.1

K. MALIK.

#### The Lazy Eye

SIR.—Among five hundred lads between the ages of 16 and 18 examined in the last two years, twenty-two (4.4%) had a visual acuity of 6/18 or less in one eye. This figure is considerably lower than that quoted by Dr. G. C. Dansey-Browning in his letter (Nov. 15, p. 796); nevertheless, it is still a significant proportion, especially when it is realized that such a disability may be the cause of a youth's not being able to embark upon the career on which he has set his heart. I would therefore like to add weight to the plea for the recognition of this problem. If the majority of these visual defects are preventable without too much difficulty, there is every reason for suitable treatment being undertaken. From personal experience I can vouch for the fact that much heartburning and disappointment in later years would thereby be avoided.—I am, etc.,

London, E.1.

ALAN WATSON.

#### Snoring

SIR.—You report Mr. V. E. Negus as stating (Nov. 22, p. 835) in the course of the discussion on Mr. I. G. Robin's interesting and instructive paper on above subject that the horse, cow, and cat would be incapable of snoring. There are certainly many exceptions to this rule in the case of cats; but it must be confessed that snoring will only take place when the particular animal relaxes into a sleep which is, for it, unnaturally deep; and this in its turn will never occur except when the cat is in a sanctuary which it believes to be absolutely inviolable.—I am, etc.,

London, W.5.

FRANK CROSBIE.

#### Health Regulations for Air Travel

SIR.—I found Dr. R. H. Barrett's article (Nov. 8, p. 741) most interesting and helpful. Hardly a day passes without an inquiry on behalf of someone going abroad as to the necessary protective inoculations. In most cases it seems that the person going abroad receives from the shipping or airways company a communication giving a definite date of departure together with advice as to the inoculation procedure which must be completed before leaving this country. The person concerned then usually consults his own doctor, who in many cases turns for advice and help to the health department.

In order to assist these cases a weekly clinic has been started, and, provided there is prior knowledge of who to expect, the

necessary inoculations against typhoid, tetanus, typhus, and cholera can be undertaken. This service has been much appreciated, but in many cases the time available before embarkation is too short to allow even the necessary injections to be given and certainly is insufficient for full immunity to develop. This is such a frequent occurrence and is so irritating to all concerned that I am writing to inquire whether anything can be done by the medical staff of the shipping and airways companies to ensure that a person proceeding abroad has full information as to the protective inoculations required sufficiently early for these to be carried out in a satisfactory and effective manner.—I am, etc.,

Leeds.

J. F. WARIN.

### Research on Ageing

SIR.—In a previous communication to the *Journal* (Nov. 23, 1946, p. 796) Dr. J. H. Hannan emphasized the importance of extending the work of medical research from the hospital and laboratory so as to include the wider investigation of disease under field conditions. In this connexion the research work at present being carried out in relation to the process of ageing at once came to mind. There is a section of the population which could make a useful contribution to accurate and first-hand knowledge on this subject. I refer to members of the medical profession who belong to the 65-plus age group. Members of this group, many of whom are retired, are in a position to take a personal and practical interest in this branch of research work. They have the necessary knowledge and experience to assess the signs and symptoms of physiological ageing and to recognize those premature changes which are to be regarded as of pathological significance. The employment of members of the profession belonging to this group by a research unit for a field survey would yield reliable information on various problems relating to the process of ageing.—I am, etc.,

Helensburgh, Dumbarton.

H. HYSLOP THOMSON.

### Road Accidents

SIR.—With reference to letters in your recent issues and statements in the public press upon this subject, it may be of interest to stress the fact that road accidents now occupy an important place in our mortal statistics. In my opinion the theory that the majority of road accidents are due to ignorance of driving matters, car manipulation, and so forth does not go deep enough. I submit that in the majority of cases it is not ignorance of driving and mechanical matters that cause accidents, but psychological faults which cannot be detected by driving tests. I am not suggesting that driving tests should be abandoned, but there are certain people who are by nature particularly susceptible to accidents, and this personal psychological factor (possibly in part genetically determined) should be investigated to discover what particular factor is associated with accident proneness.

The constellation of causes is made up of several factors, and in all probability the psychological factor is the most important. Certain psychological tests yield significant correlation coefficients between the scores obtained and accidental rates. Jung was of the opinion that accidents of every sort, in greater number than the public ever suspect, were of psychological origin. The tests are not perfect (few tests are), but they would enable us to eliminate unsuitable people from those proposed as car drivers. Whether it is reasonably practicable to carry out such tests is another matter.

Halifax.

G. C. F. ROE.

SIR.—Mr. T. C. Foley's letter (Nov. 22, p. 843) outlining the views and policy of the Pedestrians' Association is an excellent example of what may happen when a body of men forgets the debt which it owes to common humanity and chooses one of its activities in which to bind itself together. In this case the party bond is not more significant than the particular mode of transport which the members favour, and yet this bond, as I pointed out in my article (Oct. 18, p. 623), is enough to influence judgment and policy beyond reasonable limits.

All parties can quote cases to prove their point, and the truth is not, as Mr. Foley suggests, that the law is not enforced

because magistrates are motorists, but because there is no strong public conviction that the restrictive laws affecting road users are either effective or enforceable. Magistrates, like most of us, are not only motorists but also pedestrians, cyclists, "trainists," "bussists," and "taxists" at varying periods of the day, and their emotions and judgment vary accordingly.

Mr. Foley's policies of low speed and strict law enforcement and of segregation of traffic attempt to solve the problems merely by restrictive legislation, a course which will commend itself to few unless it is accompanied by a vigorous campaign to learn more about the human causes of accidents as well as the mechanical, so that we may know what laws to pass and how to segregate traffic in a way which the community will support with confidence. Meanwhile, it may even be possible by study to discover how to tame and domesticate this wild animal instead of going to all the trouble and expense of building a cage strong enough to confine him for ever. I would submit, Sir, that my plea for organized research into the psychological causes of accidents is not more remote from reality than the solution proposed by the Pedestrians' Association.—I am, etc.,

London, W.1.

KENNETH SODDY.

### A Suggested Memorial

SIR.—Many friends of the late Walter Rowley Bristow have expressed a wish to share in a memorial to him. It has been suggested that his life and work would be best commemorated by the foundation of an annual or biennial Memorial Lecture, to be delivered, if circumstances permit, alternately in Great Britain and in the United States, the two countries in which he was acclaimed as an outstanding leader in orthopaedic surgery, and where he was held in such warm regard. When a sufficient endowment fund has been accumulated it will be entrusted to the British Orthopaedic Association. Contributions to this fund are now invited, and can be sent to Mr. George Perkins, 149, Harley Street, London, W.1.—We are, etc.,

G. R. GURDLESTONE,  
CHARLES MAX PAGE,  
GEORGE PERKINS,  
HARRY PLATT.

### POINTS FROM LETTERS

#### Reduction of Certificates

Dr. L. S. WOLF (London, N.W.11) writes: I noticed in to-day's *Daily Telegraph* that the Minister of Health has appointed a committee to advise on the practicability of reducing certificates. This is long overdue. I suggest that the following reductions might be made: (1) Surgical belts; (2) the first date of absence from work (the first and last certificates could be combined in one); (3) Milk certificates could be in some cases made out for longer periods; (4) panel certificates for sick benefit could be made out for fortnightly periods as well as weekly; (5) can nothing be done to save doctors' being used so often to sign documents as witnesses of signatures—e.g., passports, lost coupons, pensions, etc.?

#### Mental Health and World Citizenship

Major JOHN STARTIN, R.A.M.C. (ret.) (Beaworth, Devon), writes: Quoting from Dr. J. R. Rees's letter in the *Journal* of Nov. 22 (p. 837): "It is, however, far from easy in these busy days to get men and women to settle down to serious discussion and to formulate their ideas on paper for the benefit of other people: but this is what we want." In his closing paragraph he says: "I hope that this letter may be taken as an invitation of a somewhat urgent kind to those who feel a concern about these matters to do something . . ." I would suggest that the laws of lunacy and the general treatment of patients should be one of the first matters under discussion by the Congress. This to my mind is a fundamental in the treatment of the mentally afflicted, and until these matters are straightened out no real progress can be made in alleviating the lot of suffering humanity who fall into this class.

The Institute of Almoners has recently issued a statement on the functions and organization of an almoner's department. The duties of the almoner are described in detail in connexion with medical social work; other work within the hospital or clinic concerned with teaching and research; and work in co-operation with other social services and health organizations. Staffing and accommodation are discussed and for the benefit of employing bodies emphasis is laid on the need for the creation of an effective department as distinct from the mere appointing of "an" almoner.

PENICILLIN Glaxo—is known and used by medical men  
in more than 40 countries.

*In China they write it this way . . .*

### for parenteral use:

Dry sodium salt in two forms, for injection in aqueous solution. No refrigeration required when stored in dry state.

PENICILLIN G<sub>LS</sub>—Freeze-dried. Potency individual vials stated in units per milligram on each vial.

CRYSTALLINE PENICILLIN G G<sub>MS</sub>—Contains over ninety per cent penicillin G, the remainder comprising other penicillins. Potency not less than 1,600 units per milligram.

† PENICILLIN OIL-WAX SUSPENSION G<sub>MS</sub>—300,000 units of calcium salt per cc. in oil and beeswax. Improved fluidity.

\* PENICILLIN OILY INJECTION B.P. G<sub>MS</sub>—125,000 units of calcium salt per cc. in oil and beeswax. Improved fluidity.

\* S. 101 as limited evidence. † Noted in the literature.

### for local treatment:

† PENICILLIN LOZENGES B.P. Glaxo—500 units of calcium salt per lozenge.

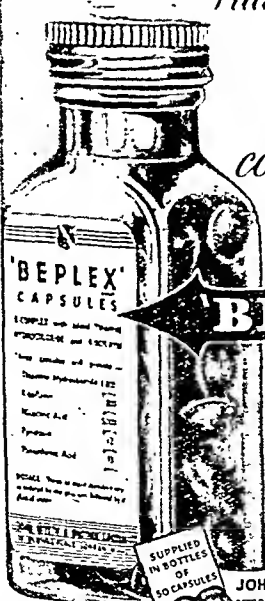

† PENICILLIN OINTMENT B.P. Glaxo—500 units of calcium salt per gram. Non-aqueous ointment; has the important practical advantage of increased stability.

PHEG

**THE ANTI-PSYOCYANEA COMPOUND**

**H**ERE is an important new bactericide and antiseptic. Phenoxetol (Nipa) is B-phenoxyethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds . . . abscesses . . . indolent ulcers . . . associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxetol is very effective in *pyocyanea* infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

### CLINICAL USES

As a general dietary supplement: in restricted diets, gastro-intestinal diseases: in fluid and light diets: in low fat and other special diets: hyperthyroidism and other states with raised B.M.R.: in chronic infections: throughout convalescence. Also for replacing other preparations of more limited application where full therapeutic doses of the vitamins are not required

\* The recommended adult daily dose provides:  
vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B<sub>1</sub> 0.6 mg., vitamin C 20 mg., calcium 160 mg., iron 68 mg.: iodine, manganese, copper, not less than 10 p.p.m. each.

HANDS AND THE MAN . . . NO. 3

Mr. . . . . .,  
*Specialist in Neuro-Surgery*

Those hands which go about their delicate task of incision and excision must always have their work sealed with flawless ligatures and sutures. It is by no means easy to make really good, consistent sutures, but the Ethicon products are prepared under ideal conditions by an organisation that is determined to maintain its position of leadership in suture quality. All Ethicon sold in Great Britain is entirely British Made.

## Obituary

W. KING HUNTER, LL.D., D.Sc., M.D., F.R.F.P.S.G.

we announce with regret the death, on Nov. 7 at the age of 80, Prof. Walter King Hunter, one of the most distinguished physicians of his generation in Scotland, and for over twenty years Muirhead Professor of Medicine at Glasgow. The active years of his life were spent in the service of Glasgow Royal Infirmary, where he was in turn student, house-physician, and member of the visiting staff. He was in charge of wards here from 1911 until his retirement in 1934. From 1903 until his appointment at the age of 44 to the newly instituted Muirhead Chair of medicine in 1911 he was lecturer in the practice of medicine at Queen Margaret College.

Hunter's early education was at the Glasgow Academy. He then entered the University, and graduated B.Sc. in 1888 and I.B., C.M. in 1890. Seven years later he proceeded M.D., and in 1901 he obtained the D.Sc. The University conferred on him the honorary degree of LL.D. when he retired from his professorship, and he was a fellow of the Royal Faculty of Physicians and Surgeons, and held various offices in the Faculty, including examinations in medicine for the licence and for the fellowship. Hunter had been on the staff of the Glasgow Royal Infirmary for Sick Children in his younger days, and he served a later years on the hospital board of governors.

During the 1914-18 war Hunter was a medical specialist, with the rank of major, on the staff of No. 4 Scottish General Hospital. For some years before his retirement he was consulting physician to the Glasgow Royal Mental Hospital, and he was one of the founder members of the Association of Physicians of Great Britain and Ireland. He also took an active part in the work of the local medical societies, holding various offices, including that of president of the Glasgow Royal Medico-Chirurgical Society. In earlier years Hunter spent some time on the Continent, visiting various clinics and studying particularly neurology in the Paris hospitals. This laid the foundation for a lifelong study of neurological problems, with which he combined a keen interest in haematology. His work in these two subjects alone formed the basis for a number of publications, including a small monograph on the anaemias.

Hunter was not an easy man to know. His rather formal speech and mannerisms tended to give a false impression of the man as he really was. Perhaps his most characteristic trait was a horror of overstatement and of flamboyance in speech, behaviour, and dress. What is now called "shooting a line" was abhorrent to him. To the man who was interested in learning clinical medicine his teaching was an inspiration and his equanimity an example. "Uncle Walter," as he was called by generations of students, will long be remembered with the late W. R. Jack, John M. Cowan, John McKenzie Anderson, and others, happily still with us, who carried on the clinical tradition of the Auld Hoose. One of the secrets of Hunter's happiness was the variety of his interests. He was deeply read in general as well as in medical literature. His appreciation of music, poetry, and painting was founded on a real knowledge of these arts, and he was devoted to quiet rural pursuits. All these were elements in the background of a busy life spent in the service of the community. When he was presented for the honorary degree of LL.D. he was described as "a great teacher and clinician, an original and advanced thinker, who had left his mark for all time on the Glasgow School of Medicine."—J. N. C.

P. L. GIUSEPPI, M.D., F.R.C.S.

Paul Leon Giuseppe died at his home in Felixstowe on Nov. 10 at the age of 66. Dr. Giuseppe, the son of a planter, was born in Trinidad, in the West Indies, where he received his early education. In 1900, on winning a Trinidad Major Island Scholarship, he came to this country to study medicine at St. Bartholomew's Hospital. There he won several awards, including the Jeaffreson Exhibition in 1900, the Junior Scholarship in 1901, and the Senior Scholarship in 1903. Dr. Giuseppe took his M.R.C.S. and L.R.C.P. in 1905, and in the following

year graduated M.B., B.S., with honours in medicine, hygiene, and midwifery and gynaecology. He took the F.R.C.S. in 1907, and proceeded M.D. two years later. He also studied in Paris at the Pasteur Institute. Later he was a house-surgeon at the Royal Free Hospital and senior resident medical officer at Queen Charlotte's Maternity Hospital and at the Royal Waterloo Hospital. In 1910 Dr. Giuseppe went into partnership with the late Dr. Havell at Felixstowe, where he practised until his death. There he was senior surgeon to the Cottage Hospital, and also public vaccinator. During the 1914-18 war he was surgeon in charge of the Cliff Hospital in Felixstowe, and was responsible for naval and military units in the area. In the recent war he was surgeon to the E.M.S. Hospital as well as to various units of the Services. He acted as divisional surgeon to the St. Felix division of the St. John Ambulance Brigade, and served with the rank of major in the Home Guard.

Dr. Giuseppe served on the Council of the British Medical Association for several years, and was secretary of the Suffolk Branch for 28 years, a period of service interrupted only by his presidency of the Branch in 1933-4. To his local activities Dr. Giuseppe brought the same enthusiasm that he gave to his profession. He was a member of the urban district council from 1914 to 1947, a period that included three terms as chairman. Many local sporting, social, and cultural associations found in him a chairman or president who was no figurehead but took an active part in the running of each.

It was, however, in his hobby of collecting alpine plants that Dr. Giuseppe achieved fame beyond the limits of this country. His success in cultivating these plants brought letters from all over the world. He was not content merely to cultivate, but spent his holidays collecting specimens from the mountains of Persia, Russia, Spain, Portugal, the Balkans, and Crete. He discovered many new plants, and one was named after him by Kew Gardens. He was well known in the mountainous districts of these countries, and often after a hard day's climbing he would hold an informal surgery in the villages, many of which seldom saw a doctor. His enthusiasm was partly responsible for the formation of the Alpine Garden Society, of which he was honorary treasurer from its inception until his election as president in 1945. In the last weeks of his life he received from the Royal Horticultural Society their highest award, the Victorian Medal of Honour. Among other associations to which Dr. Giuseppe belonged were the Royal Geographical Society, of which he was a fellow, the Royal Central Asian Society, and the Alpine Club.

Whatever the activity Dr. Giuseppe was engaged in, his energy seemed endless and his thoroughness and enthusiasm were remarkable. In his own mind he carefully turned over the pros and cons of any suggestion and, having made up his mind to the correct course of action, he would support it fearlessly and in forthright fashion. He was outspoken in his criticism of ideas and points of view of which he did not approve, and inevitably this led to some opposition which in no way deterred him from the course of action which he judged to be correct. Looking back over the years it is surprising how seldom one can find errors of judgment even though his point of view was not always accepted. In his professional work this same forthrightness and self-confidence stood him in good stead with his patients, who had complete trust in him and who treated him not only as a doctor but with affection as a guide and friend.

Dr. Giuseppe married in 1910 Andrée Centeno, who died in 1942. He was married again in 1944 to Constance Browning, who survives him, as do his three sons by his first marriage.

SIR WILLIAM H. COLLINS

Sir William Henry Collins, who died at Wexham Park, Buckinghamshire, at the age of 74 on Nov. 30, will be remembered as a benefactor of the Middlesex Hospital, the King Edward VII Hospital at Windsor, and, more especially, of the Royal College of Surgeons of England.

William Henry Collins joined the Cerebos Salt Company in his youth and became managing director in 1916. He was also associated with other large companies. He was keenly interested in the welfare of the sick and a great admirer of the medical profession. He once said that he owed the profession "a debt I can never fully repay." His first considerable benefaction was a gift to the Middlesex Hospital of £25,000

in 1933. This was used to provide what has since been known as the Collins X-ray Department. He was a member of the board of management of the Middlesex Hospital, and later a vice-president.

He became chairman of the Kind Edward VII Hospital at Windsor in 1938, a position which he relinquished only in January of this year. He was an active and energetic chairman, taking the greatest interest in the development of the hospital. At different times he defrayed the cost of new boilers for the hospital, gave the sum of £25,000 towards the rebuilding of the out-patients department, and made other substantial gifts. Even after he had ceased to preside over it he remained a member of the hospital board, and he was also one of the trustees of the hospital.

His first great benefaction to the Royal College of Surgeons was a gift of £100,000 in October, 1943. This was used for the endowment of the department of pathology and to institute a chair of human and comparative pathology. In a letter which he wrote to Sir Alfred Webb-Johnson at that time Mr. Collins, as he then was, said: "It is essential that the Departments should have an assured income from endowments. . . . I trust that my gifts will enable the Council to proceed with confidence with their responsible task, and to engage the services of men of outstanding ability to assist them in their labours." Shortly afterwards the appointment of Prof. R. A. Willis was announced. In 1944 Sir William was awarded the Honorary Medal of the College. In March of the following year he gave a further £100,000 to endow the department of anatomy and to found a chair to which Prof. F. Wood Jones, F.R.S., was elected in June of that year. Sir William, who was knighted in 1944, was admitted an Honorary Fellow of the College on Jan. 10, 1946, at the same time as Sir Henry Dale.

His last gift was a third sum of £100,000 to provide increased endowments for the scientific departments generally. It will be recalled that this gift was conditional on an offer being made to the Royal College of Physicians of a site to the east of the Royal College of Surgeons in Lincoln's Inn Fields.

Colonel CYRIL HENRY HOWKINS died on Oct. 31 at the age of 71, after three months' illness, during which his courage maintained his good spirits and his mental alertness was unimpaired. He was a student of Birmingham University, and he took the L.D.S. in 1899. Then immediately after qualifying M.R.C.S., L.R.C.P. in 1901 he served as a medical officer in the South African War and gained the Queen's Medal, with four clasps. Subsequently serving as a volunteer, he played an active part in the Territorial Army in Birmingham, and particularly in raising the 1st South Midland Field Ambulance, which he commanded from 1910 to 1917, serving with it in the Battle of the Somme; for this he received the D.S.O. He was then promoted to be A.D.M.S. of the 61st Division in France, being one of the first Territorial officers to gain such an appointment. He was four times mentioned in dispatches and was decorated with the C.B.E. Later he received the Territorial Decoration and became a deputy lieutenant of the County of Warwickshire. From 1901 until his final illness he practised with signal success as a dental surgeon. In 1905 he joined the honorary staff of the Birmingham Dental Hospital, and from 1925 to 1945 he acted as its dean and gained the full confidence of the committees and of the students, in itself no easy task. For twenty years he was honorary dental surgeon to the Birmingham Children's Hospital, and for ten years examiner in dental surgery to the Royal College of Surgeons. At different times he was an examiner for the University of Sheffield; president of the Central Counties Branch of the British Dental Association and of the Section of Odontology of the Royal Society of Medicine; president of the Birmingham Medical Institute; chairman of the Association of Dental Hospitals of Great Britain and Northern Ireland, and of the Warwickshire Dental War Committee; joint honorary secretary of the Dental Education Advisory Council; and from 1939 to 1945 he was acting professor of dental surgery at the University of Birmingham. In all these offices his energy, shrewdness, and tact made him an outstanding success and he became one of the best-loved and most respected figures in his profession. In 1928 he was invited by the Dental Board of the United Kingdom to give a series of lectures on the anatomy of local analgesia. He also did valuable work in Birmingham in devising applicators for intracranial radium in the treatment of carcinoma. He was keenly interested in Freemasonry and became Master of the Grosvenor Lodge. He was made Past Provincial Junior-Grand Warden

of Warwickshire in 1928. He was also a founder of the Lodge and the University of Birmingham Lodge. He is by his widow, two sons, one of whom served as a major R.A.M.C., and a married daughter who is medically qualified.—W.B.

JOHN NATHANIEL BEADLES died on Nov. 1 at the age of 71 after a short illness. He qualified L.M.S.S.A. from theminster Hospital in 1910, and went on to graduate M.B. in the same year. After filling various house appointments his own and other hospitals he went into private and later served in the R.A.M.C. in the 1914-18 war; joined the L.C.C. as a part-time school doctor in 1918, was appointed a full-time A.M.O. in 1935. Dr. Beadles of a long line of doctors from the time of Elisha Beadles was in practice as an apothecary in Pontypool and published a book on medicine in 1689. He wrote articles on various subjects, mainly relating to infectious diseases, and had outside interests, being a keen chess player and a life member of the St. John Ambulance Association. His wide experience in his profession stood him in good stead in his public work, and he devoted much time to the problem of men with subnormal children. His modest and unassuming manner endeared him to his colleagues and to all who came into contact with him. He will be much missed by a large circle of friends and acquaintances and by the parents and children whom he took a great interest. He leaves a widow and daughter.

Dr. ELIZABETH COWPER EAVES died in Sheffield on Nov. 1 after a short illness. She was appointed demonstrator in physiology at the University of Sheffield in 1909, when she held a London B.Sc., and she continued to work in this department until the time of her death, serving under four professors, specializing in neuro-histology, devising in particular special methods of staining the tissues of the nervous system. Colour vision was also a subject in which she was interested, and she had just completed a paper presenting the results of detailed observations over a period of years. She graduated M.B., B.S. in 1922, obtained her D.P.M. in 1924, and took the London M.D. in 1925. Dr. Eaves was president of the local association of the Medical Women's Federation for many years, and spared no effort to obtain equality for women students, especially in the question of resident student posts. She also conducted a follow-up study of all the women students from Sheffield who had qualified in the last thirty years. The Medical Women's International Association was one of her special interests, and she acted as international corresponding secretary for many years before 1939. Throughout the recent war Dr. Eaves spent her vacations doing locum tenens appointments, mainly in hospitals for nervous diseases. She was a very gifted pianist and was devoted to her family and her work.

Dr. ROBERT CARMICHAEL WOOD, a well-known general practitioner in Edinburgh, died from acute poliomyelitis at the age of 39 in the City Hospital on Nov. 23. A student of Edinburgh University, he graduated M.B., Ch.B. in 1932, took the M.R.C.P.Ed. in 1936, and only last year became a Fellow of the Edinburgh Royal College. A younger son of the late Dr. W. W. Wood, who practised in the Comely Bank district of the city, he had been connected for a number of years with the Sick Children's Hospital, Edinburgh. In the recent war he served with the 8th Battalion the Royal Scots until 1941, when he was transferred to the 57th General Hospital in Cyprus. Later he was with the 92nd General Hospital in Naples.

R. W. D. T. and G. A. G. P. write: The sudden and unexpected death of Bobbie Wood from poliomyelitis will cast a deep shadow over the minds of the many friends he possessed. Those who knew him, whether in Edinburgh before and after the war or in the R.A.M.C. during his six years' service in Britain, the Middle East, and Italy, will always remember him for his absolute honesty, loyalty, and cheerfulness, and as the finest type of doctor—thorough, kindly, and wise, with the welfare of the patient his first consideration always. On his return from war service he rapidly built up an extensive practice, and was appointed an assistant physician to Leith Hospital. He will be sorely missed by his many patients as well as his many friends in all walks of life. To his young widow and to her two small children goes the sympathy of all who knew him.

A Memorial Service for the late Mr. W. Rowley Bristow was held in the St. Thomas's Hospital Chapel on Nov. 21. The Bishop of Rochester officiated, assisted by the Reverend H. Hedley.

## Medical Notes in Parliament

### NATIONAL ASSISTANCE BILL

On Nov. 24 the Minister of Health moved the Second Reading of the National Assistance Bill, the terms of which were discussed in a leading article in our issue of Nov. 8 (p. 736).

Mr. BEVAN said that under the Bill the welfare authorities would have a special responsibility for those who were suffering from pulmonary tuberculosis. The Government proposed to continue the scheme adopted during the war to encourage early cases to give up their jobs and to undergo treatment. They proposed to end the provision that the allowances made to such persons ceased when it was found that the condition was incurable. Pulmonary tuberculosis, like other forms of illness, would be the responsibility of the National Assistance Board on the one side and the Regional Hospital Boards on the other, the former making the financial provision and the latter providing the treatment. The Government proposed to place upon the Assistance Board the duty of providing maintenance for the blind and upon local authorities a duty to make special schemes for their training and welfare. A larger measure of responsibility would be accepted for old persons. Welfare authorities would be given powers to establish special homes. Other categories of persons requiring assistance included the deaf. When the National Health Service came into operation the Government hoped there would be a large number of hearing-aids ready for free distribution to the deaf. Other persons handicapped congenitally or through accident would be attended to and would be taught occupations. This would be the responsibility of the welfare authority, dovetailing into the Ministry of Labour.

Mr. WALTER ELLIOT approved the Bill. He was glad the Minister was extending the tuberculosis schemes introduced by the Coalition Government. That would place on the Government a still greater responsibility for finding nursing staffs. He drew attention to Clause 45, under which any person who was aged or infirm could be removed from his house on the certificate of one medical officer of health, supported by the Court, and placed in a hospital or other place within or without the area of the appropriate authority and detained therein. Under the existing law in most cases at least two certificates were necessary before the removal of a citizen from his house and his detention on an indeterminate order. One medical certificate was needed to remove a person from his home if he was deemed to be insane, but subsequently two certificates must be obtained. He thought that wider safeguards might be necessary.

Mr. EDWARD EVANS was sorry to see that the definition of blindness in the Act was taken from the Blind Persons Act, 1920. This was a bad definition because it imposed on a medical man the obligation not only to make a medical assessment of a person but to relate it to his capacity for work. It was not the function of a medical man to make an industrial appraisal.

Mr. SOMERVILLE HASTINGS said he was grateful that under the Bill the cost of hospital treatment could not be counted as means. It was true that State pensions would be adjusted, but aged persons would have some pocket money while they were in hospital. He remarked that in 1944, when he visited evacuated people in various parts of England, he found both old people and children were well treated in nearly every case, but whereas the children were happy nearly all the old people were miserable. He therefore felt that in the homes which the Bill would set up there must be as much freedom as possible and little restriction on visitors or on coming in or going out.

Dr. BARNETT STROSS said the provisions of the Bill in regard to pulmonary tuberculosis would make life much easier for country medical men.

Mr. JAMES GRIFFITHS replied for the Government and the Bill was read a second time without a division.

### Calories

On Nov. 17 Mr. E. P. SMITH said the British Medical Association's *Report on Nutrition* in 1933 demanded 3,400 calories as the minimum daily diet to maintain working efficiency. For persons doing heavy labour 3,500 to 4,000 calories was thought to be desirable. The report stated that a reduced food intake, in the neighbourhood of 2,000 calories, gave rise to disorders of digestion. Questions put recently to the Ministry of Food had disclosed that in rationed and in pointed foodstuffs the daily average intake was now 1,530 calories. He had further discovered that very few got the

other 1,340 calories from unrationed foodstuffs. The Ministry of Food made its calculations by dividing the amount of unrationed food consumed in the country by the number of the population. An old couple in a lonely village were consequently estimated to receive 2,870 calories daily, when in fact their daily intake was probably less than 2,000. A man in gaol in 1938 received from 2,994 calories to 4,200 calories daily and a woman from 2,542 to 2,901. In 1947 a man in gaol received from 2,923 to 2,955 calories daily; a woman received 2,541 to 2,605; a boy in a Borstal institution got from 2,987 to 3,051 calories; and a girl 2,521 to 2,585. In a *dietetic* sense it paid to be in gaol. The averages which the Ministry of Food paraded were useless because the bases on which they were calculated as regards unrationed food were completely unsound.

Dr. SEYMOUR SKILL said foods must be reduced to a common denominator to make an addition and therefore the calorie must be brought into the calculation. The Combined Food Board adopted the calorie during the war and not the Ministry of Food. All the Ministry did was to quote calorie values assessed as the Combined Food Board had assessed them. The consumption levels quoted by the Ministry of Food were the average consumption for the whole country, and the average calorie intake of 2,800 included an intake of 900 calories by an infant and of 4,500 by a heavy worker. The intake of an adult man might vary from 2,500 calories to 4,500 daily, and of an adult woman from 2,000 to 3,000 calories daily. The nursing mother got about 3,000 calories a day. The average for the agricultural worker was 2,600, but the extras which he got during seasonal activities raised it to well over 3,000, and unrationed food brought his intake up to over 4,000 calories. One hot meal a day equalled 900 calories and one snack equalled 500 calories. Members must make these additions when they calculated the average for a family where the wage earner took his meals outside.

### Medical Practitioners and Pharmacists Bill

The House of Lords passed the Medical Practitioners and Pharmacists Bill through the Report Stage on Nov. 25, and read it a third time on Nov. 27, in each case without debate. Its Second Reading in the House of Commons was set down for Dec. 5.

*Uganda Medical Services.*—Mr. CERRILL JONES stated on Nov. 26 that in the Uganda Development Plan £1,500,000 was earmarked for medical and health services. It was essential to the training of African medical officers and to the efficiency of the dispensary system that a fully equipped central hospital should be established. Accordingly a grant of £477,500 had been approved from Uganda's territorial Colonial Development and Welfare allocation for the building of a new central teaching hospital at Mulago, Kampala. £100,000 was also provided for new hospital buildings, dispensaries, and health centres. There must be a teaching hospital in East Africa if African doctors were to be trained. At the same time, the ten-year programme placed great emphasis on preventive medicines and on dispensaries.

## The Services

The Queen of the Netherlands has bestowed the decoration of Commander of the Order of Orange-Nassau upon Surgeon Captain J. C. Souter, R.N., in recognition of services rendered to the Royal Netherlands Navy during the war.

The King of Norway has bestowed the decoration of Commander with Star of the Order of St. Olav upon Surgeon Vice-Admiral Sir Sheldon Francis Dudley, K.C.B., O.B.E., F.R.S., for service to the Norwegian Navy Medical Service during the war, and the Queen of the Netherlands has bestowed upon him the decoration of *Grand Officer* of the Order of Orange-Nassau, in recognition of services rendered to the Royal Netherlands Navy during the war.

The following officers have been awarded the Efficiency Medal (Territorial): Major A. Wilcox, Captain (now Temporary Lieutenant-Colonel) J. F. Hedley, Captain (Honorary Major) S. G. Cowper, Captains (now Majors) W. B. Evans and E. H. Hanson, and Captain W. F. de Coverly Veale, R.A.M.C.

### NORTH PERSIAN FORCES MEMORIAL AWARD

Dr. John Norrie McArthur, F.R.C.P., has been awarded the North Persian Forces Memorial Silver Medal for 1946. The medal is awarded every year for the best paper on tropical medicine or tropical hygiene published in any journal during the 12 months ending Dec. 31 by any medical officer of under 12 years' service in the

Royal Navy, the Royal Army Medical Corps, the Royal Air Force, the Indian Medical Services, or the Colonial Medical Service. Dr. McArthur was awarded the medal for his paper on "Malaria Transmission in Borneo" which was published in the *Lancet*.

### DEATHS IN THE SERVICES

Sir THOMAS O'DONNELL, K.C.I.E., C.B., D.S.O., L.R.C.P.I., was born on Jan. 18, 1885. He was the third son of the late P. O'Donnell, High Constable of the Barony of Glenquin, of Killeedy, Ashford, County Limerick. He qualified L.R.C.S.I. in 1879 and L.R.C.P.I. and L.M. in 1880, and in the following year was serving with the Field Artillery in Egypt. Later he served with the Kimberley Light Horse under Sir C. Warren in the Bechuanaland Expedition of 1885-6. In the Zululand campaign he was with the Inniskilling Dragoons and later he was attached to the Rifle Brigade. In the South African war he was mentioned in dispatches twice and awarded the D.S.O. for his services with the 12th Royal Lancers.

Colonel S. Lyle Cummins, late A.M.S., writes: The death of Sir Thomas O'Donnell has come as a great shock to all who, like myself, were closely associated with him during the opening phases of the 1914-18 war. "O.D.," as he was called by all who knew him, came to France as D.D.M.S. of the 1st Corps and from that time until his departure as D.G. in India he was the heart and soul of the medical directions that emanated from G.H.Q. It is to him that thanks must be given for a thoroughly good medical service in the period before the arrival of Sir Arthur Sloggett as Director-General in 1915. His kindness to me and to the many officers who "drifted in" to G.H.Q. during that long and difficult period I shall never forget. His work later as D.G. in India is a matter for another pen than mine, but I fancy that, as medical officer to G.H.Q. at that time, I can speak with authority about the eminent services that he rendered and the goodness and kindness of the "unofficial" D.D.M.S. to all and sundry at G.H.Q.

## Universities and Colleges

### UNIVERSITY OF ABERDEEN

At a meeting of the Senatus of the University on Nov. 26 the Venn Prize in Pathology was awarded to J. A. Shanks (Aberdeen) and the Fulton Prize in Neurology to W. I. Cranston (Galashiels).

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

The by-laws of the Royal College of Physicians of London have been amended in order that at least two general meetings of Members shall be held each year, and to allow for the appointment of a standing committee which shall concern itself with the interests of Members. These changes have been made with the intention of giving Members more voice in the affairs of the College. The first statutory meeting of Members was held at the College on Nov. 27, with Lord Moran, President, in the chair. One hundred and thirty-three Members attended, and the following were appointed to serve on the standing committee: Lord Moran, President (ex-officio), Dr. W. R. S. Doll, Chairman, Dr. M. J. McArdle, Secretary, Dr. H. S. Morley, Dr. E. Halliwell, Dr. J. Holmes, Dr. J. F. Bromley, Dr. P. L. Mollison, Dr. W. J. O'Donovan, Dr. J. H. Hunt, Dr. E. Bywaters, Dr. C. Wilson, Dr. G. E. F. Sutton, Dr. A. Leishman, Dr. E. Darnady, Dr. K. A. Latter, Dr. R. Johnstone, Dr. R. Cove-Smith, Dr. J. R. Forbes, Dr. Helen Dimsdale, Dr. W. E. Gibb, and Dr. J. F. Loutit and Dr. L. W. Batten (ex-officio). Dr. Loutit and Dr. Batten were elected representatives on the Council of the College.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

A course of 72 lectures in anatomy, applied physiology, and pathology will be given at the College (Lincoln's Inn Fields, London, W.C.) from April 5 to May 25, 1948. There will be two lectures daily (Monday, Tuesday, Wednesday, Thursday, and Friday) at 3.45 p.m. and 5 p.m. The fee for the whole course is £16 16s. Fellows and Members and Fellows and Licentiates in Dental Surgery of the College will be admitted on payment of a fee of £12 12s. The closing date for applications is Saturday, April 3, 1948.

A series of practical demonstrations in the above subjects will be held at the College from March 22 to June 11, 1948, from 10 a.m. to 1 p.m. and from 2 p.m. to 3.30 p.m. daily. The fee is £21, and the closing date for applications is Monday, Feb. 2, 1948. The demonstrations will be open only to those attending the above-mentioned lectures and will be limited to 40 students; preference will be given to those unable to obtain practical instruction elsewhere and to ex-Service men.

Applications, accompanied by a cheque for the appropriate fee, should be sent to the secretary, Postgraduate Education Committee, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2

## Medical News

### Visitor from Australia

Dr. Arthur Metcalfe, the Australian Director-General of and Quarantine, will leave Australia on Dec. 14 for a three tour of Britain, Canada, and the U.S.A. to investigate all aspects of public health. He will pay particular attention to quarantine in relation to air travel. Dr. Metcalfe will travel under the Rockefeller Foundation Grant.

### London Association for Hospital Services

Dr. W. Russell Brain, F.R.C.P., has been elected chairman London Association for Hospital Services in succession to Bernard Docker, who will continue to serve as a member of Council.

### Award for Research

The gold medal in memory of Daniel Hanbury, awarded "high excellence" in original drug research, was presented Nov. 13 by Mrs. J. K. Irvine, president of the Pharmaceutical Society of Great Britain, to Dr. Hans Flück, Professor of Pharmacognosy in the Faculty of Pharmacy of the Swiss Federal Technical Institute, Zurich.

### Swedish Award

At its annual meeting recently the Swedish Medical Society awarded its Anders Retzius Medal to Jan Boeke, of the University of Utrecht, for his researches in anatomy.

### Sheriff for Breconshire

John Emrys Jenkins, B.M., B.Ch., of Chalfont, Llandrindod was has been nominated Sheriff in the King's Bench Division of High Court of Justice for Breconshire for 1947.

### Medical Laboratory Technicians: Deferred Call-up

A circular from the Ministry of Health states that "certificates of identification" will be issued by the Ministry to laboratory technicians in training born in 1929 or later. The holder of such certificate may apply for deferment of call-up under the National Service Acts until his training is completed—normally 3 years. This would give him the opportunity of obtaining a recognized qualification—e.g., the Intermediate Certificate of the Institute of Medical Laboratory Technology. The certificate will normally be given only to those trainee technicians who started training (a) before the age of 17, or (b) within 3 months of the end of whole time education. Deferment of call-up in other cases would have to be referred specially to the Ministry of Labour and National Service by the Ministry of Health.

### The Gordon Hospital

The Duchess of Kent formally reopened the Gordon Hospital on Dec. 2. Mr. John A. Dewar, the President of the Hospital, proposed the vote of thanks to Her Royal Highness, which was seconded by Mr. Lawrence Abel, surgeon to the hospital.

### Dr. Barnardo's Homes Christmas Appeal

There are 7,500 children in Dr. Barnardo's Homes. A Christmas gift of 10s. would pay for one child's food for a week. Gifts should be sent to Barnardo House, Stepney Causeway, London, E.C.2

### Wills

Prof. Bryan Austin McSwiney, F.R.S., dean of St. Thomas's Hospital Medical School since 1940, who died on March 8, left £12,913.

## COMING EVENTS

### Benjamin Ward Richardson Lecture

Mr. C. G. Allen will deliver the Benjamin Ward Richardson Lecture on "The Transport, Handling, and Laying of Animals Intended for Slaughter" before the Royal Sanitary Institute (64, Buckingham Palace Road, London, S.W.) on Wednesday, Dec. 10, at 2.30 p.m.

### Pharmaceutical Society of Great Britain

A lecture on "Modern Knowledge of Protein Structure and its Pharmaceutical Significance" will be delivered by Adrian Albert Ph.D., before the Pharmaceutical Society of Great Britain (17, Bloomsbury Square, London, W.C.) on Thursday, Dec. 11, at 7.30 p.m.

## Middlesex County Medical Society

A general meeting of the Middlesex County Medical Society will be held at Ashford County Hospital on Tuesday, Dec. 9, at 3 p.m., when there will be a demonstration of cases of peripheral vascular disease. Short papers by Dr. K. D. Keele, on "Diseases of the Abdominal Aorta and Its Branches," and by Dr. A. G. Signy and Major B. E. Tomlinson, on "The Chronic Appendix," will be read and discussed.

## Society of Chemical Industry

A meeting of the Nutrition Panel of the Food Group of the Society of Chemical Industry will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, London, W., on Wednesday, Dec. 10, at 6 p.m., when four papers on "Organoleptic Tests in Food Industry" will be presented.

## Royal Sanitary Institute

A sessional meeting of the Royal Sanitary Institute will be held at St. Mary's Hall, Bayley Lane, Coventry, on Friday, Dec. 12, at 10 a.m., when Mr. W. Beaumont will read a paper on "Food Contamination and Potential Dangers to the Public Health."

## Meeting of Radiologists

A joint meeting of the British Institute of Radiology, the Faculty of Radiologists, and the Section of Radiology of the Royal Society of Medicine will be held at 1, Wimpole Street, London, W., on Friday, Dec. 12, at 8 p.m., and on Saturday, Dec. 13, at 10 a.m., when a symposium on "Carcinoma of the Breast" will be presented. Mrs. E. K. Dawson, Prof. R. W. Scarff, Mr. R. C. B. Ledlie, Sir Stanford Cade, Dr. R. McWhirter, and Dr. Clemmison (Copenhagen) will open the discussion.

## Middlesex Hospital Arts Society

The annual exhibition of the Middlesex Hospital Arts Society will be held in the board-room of the hospital from Monday, Dec. 15, to Thursday, Dec. 18, and will be open from 11 a.m. to 6 p.m. on Dec. 15, 16, and 18, and from 11 a.m. to 4 p.m. on Dec. 17. One of the main sections will include the work of members of the Royal Photographic Society in which there will be two special exhibits, namely, electron photomicrographs, by Prof. J. McIntosh and Dr. K. B. Merling, and plateletic research by x rays, by Mr. W. H. S. Cheavin, F.R.M.S., F.R.P.S.

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Tuesday, Dec. 9, and Thursday, Dec. 11, 5 p.m. FitzPatrick Lectures by Sir Arthur MacNalty on the History of State Medicine in England: (1) The Medical Department of the Local Government Board, and (2) The Foundations of the National Health Services.

## ROYAL SOCIETY OF MEDICINE

*Section of Psychiatry.*—Tuesday, Dec. 9, 5 p.m. Discussion: Aggression in Relation to Emotional Development, Normal and Pathological. Openers: Miss Anna Freud and Drs. Clifford Scott, D. W. Winnicott, and John Bowlby.

*Section of Experimental Medicine.*—Tuesday, Dec. 9, 5.30 p.m. Discussion: Plasma Protein Fractions. Openers: Drs. R. A. Kekwick and N. H. Martin.

*Section of Physical Medicine.*—Wednesday, Dec. 10, 4 p.m. Clinical meeting at University College Hospital, Gower Street, London, W.C.

*Section of Comparative Medicine.*—Wednesday, Dec. 10, 5 p.m. Discussion: Nutrition and Resistance to Infection. Openers: Dr. P. H. Gell and Mr. H. B. Parry.

*Clinical Section.*—Friday, Dec. 12, 5 p.m. (Cases at 4 p.m.)

*Section of Ophthalmology.*—Friday, Dec. 12, 6 p.m. (Cases at 5 p.m.) Clinical meeting at the Moorfields, Central and Westminster Ophthalmic Hospital, Moorfields Branch, City Road, London, E.C.

*Section of Radiology.*—Friday, Dec. 12, 8 p.m. Combined meeting with the Faculty of Radiologists and the British Institute of Radiology. Symposium: Carcinoma of the Breast. Speakers: Mrs. E. K. Dawson, Prof. R. W. Scarff, Mr. R. B. C. Ledlie, and Sir Stanford Cade. Saturday, Dec. 13, 10 a.m. Symposium: Carcinoma of the Breast, continued. Speakers: Dr. R. McWhirter and Dr. Clemmison (Copenhagen).

BIOCHEMICAL SOCIETY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., Saturday, Dec. 13, 11 a.m. Symposium: Biochemical Reactions of Chemical Warfare Agents.

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 47, Queen's Gate Terrace, S.W., Tuesday, Dec. 9, 6.30 for 7 p.m. Discussion: Treatment of Disease in Wild Animals, to be opened by Mr. T. A. Cockburn, F.Z.S. Future meetings of the Society will be held half an hour later, namely at 7 for 7.30 p.m., to meet the wishes of the majority of members.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Leeds General Infirmary, Friday, Dec. 12, 8.30 p.m. Clinical meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Monday, Dec. 8, 8.30 p.m. Discussion: Teaching and Research in Social Medicine. To be introduced by Prof. J. A. Ryle.

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh.—Friday, Dec. 12, 8 p.m. Address by Prof. R. W. H. Elliot: The Effects of War on Child Health.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, London, W., Thursday, Dec. 11, 7.30 p.m. Dr. J. A. McLeitch: The Control of Sleeping Sickness in Nigeria. A discussion will follow.

## POSTGRADUATE DIARY

EDINBURGH UNIVERSITY.—Monday, May 3, 1948, 9 a.m., 121 General Forthright Refresher Course begins. Intended primarily for demobilized medical officers (Class II) and for insurance practitioners. Fee for graduates not claiming expenses from Governmental sources, 10 sh.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, Dec. 9, 5 p.m. Dr. D. M. Heilmann: Problems in the Epidemiology of Poliomyelitis.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Tuesday, Dec. 9, 5 p.m. Dr. I. Macleod: Pathological Demonstrations. Thursday, Dec. 11, 5 p.m. Dr. H. W. Barber: The Lichen Group of Eruptions.

LONDON CHURCH HOSPITAL, Victoria Park, E.—Friday, Dec. 12, 6 p.m. Mr. J. W. S. Lindahl: Sinus Infection in Chest Diseases.

A two-months postgraduate course in surgery will be held at the Royal College of Surgeons in Ireland starting on April 12, 1948. The number of students is limited to 30 and the fee is 20 guineas. Students may enrol now with the Registrar, Royal College of Surgeons, St. Stephen's Green, Dublin.

## APPOINTMENTS

Sir Frank Engledow, C.M.G., M.A., F.R.S., has been appointed chairman of the Food Investigation Board of the Department of Scientific and Industrial Research in succession to the late Sir Joseph Barcroft, C.B.E., F.R.S.

ABRAHAM, ALFRED M., F.R.C.S., Assistant Surgeon, Walton Hospital, Liverpool.

ADKINSON, P. H., M.R.C.S., L.R.C.P., Assistant Secretary, Medical Defence Union, 49, Bedford Square, London, W.C.1.

BALFORD, S. L., L.R.C.P.S.E.d., Medical Superintendent, Isle of Man Mental Hospital.

DERBY HOSPITALS JOINT CO-ORDINATING COMMITTEE.—R. J. McC. Jamieson, M.B., B.Ch., and J. G. Pritchard, M.B., Ch.B., have been appointed assistant surgeons by the committee to work with the gynaecological and obstetric units in Derby hospitals.

DONOVAN, PATRICK FERGUS, F.R.C.S.I., Associate Professor of Surgery, University of Ottawa.

LEATHAM, A. G., M.B., B.Chir., M.R.C.P., Sherbrook Research Fellow to Cardiac Department of the London Hospital.

LONDON COUNTY COUNCIL.—The following appointments have been made in the Council's mental health services at the hospitals indicated in parentheses: Assistant Medical Officers, G. J. T. Fryer, M.B., B.S. (St. Bernard's, Southall); H. Lantin, M.B., B.Ch. (Long Grove, Epsom); B. Nicholson, M.R.C.S., L.R.C.P. (Banstead); P. Sainsbury, M.B., B.Ch., D.P.M. (Hexley); J. E. G. Vincenti, M.R.C.S., L.R.C.P. (Dulwich). Second Assistant Medical Officers: E. W. Dunkley, M.B., B.S., D.P.M. (seconded to St. Pancras Hospital Mental Observation Unit); J. Johnston, L.R.C.P.A.S., D.P.M. (Claybury); P. R. A. May, M.B., B.Ch., D.P.M. (Cane Hill).

MADDOCKS, S. A., M.R.C.S., L.R.C.P., D.M.R.E., Radiologist, Hillingdon County Hospital.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTH

Leslie.—On Nov. 11, 1947, at Royal Infirmary, Bradford, to Frances Helen (née Robb), wife of Dr. William Leslie, a son.

## DEATHS

Clane.—On Nov. 15, 1947, in London, John Joseph Clane, L.R.C.P.A.S.I. Duff, —On Nov. 21, 1947, Henry Carson Duff, M.B., Ch.B.

Halt.—On Nov. 22, 1947, at C.M.S. Hospital, Ranaghat, Bengal, India, Mervyn Alexander Halt, B.M., B.Ch., aged 44.

Higgin.—On Nov. 29, 1947, at Devon Square, Newton Abbot, Robert Francis Higgin, M.D.

Hogg.—On Nov. 26, 1947, at Middlesex Hospital, London, W., Cecil Berestord Hogg, M.D., D.P.H., of 24, Warkton Lane, Barton Seagrave, aged 57.

Moxey.—On Nov. 29, 1947, at Bournemouth, Vincent Moxey, M.R.C.S. Riley.—On Nov. 28, 1947, at Ryde, Isle of Wight, Arthur Riley, M.B., Ch.B., aged 78.

Simpson.—On Nov. 26, 1947, at 54, Monkcastle Drive, Cambuslang, Scotland, Frank Tomlinson Simpson, M.C., E.D., K.I.H., M.B., Ch.B., Lieutenant Colonel.

Smith.—At Terpoint, Sandycove, Co. Dublin, Eire, Trevor Nathaniel Smith, F.R.C.S.I.

Weir.—On Nov. 25, 1947, James Samuel Richard Weir, L.R.C.P.A.S.E.d., at 10, Chatsworth Road, Wembley, Middlesex, aged 68.

## EPIDEMIOLOGICAL NOTES

## INFECTIOUS DISEASES AND VITAL STATISTICS

## Poliomyelitis

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

The notifications for the week ended Nov. 22 suggest a more rapid decline than has been shown in recent weeks. Notifications of poliomyelitis were 142 (186) and of polio-encephalitis 3 (15). Figures in parentheses are those for the week ended Nov. 15. The marked decline in the notifications of polio-encephalitis is interesting, but fluctuations under this heading have been irregular and may be of no significance.

## Discussion of Table

In England and Wales an increased incidence was recorded for scarlet fever 217, measles 176, and whooping-cough 145. There was a decrease in the notifications of diphtheria 24, poliomyelitis 12, and dysentery 10.

A rise in the incidence of scarlet fever occurred throughout the country; the largest increase was Staffordshire 25, and the only exception to the general trend was a decrease of 37 in Durham. The largest variations in the local returns of diphtheria were decreases in Lancashire 18 and Warwickshire 9.

Only small variations occurred in the incidence of whooping-cough, except for a rise of 69 in Yorkshire West Riding. A small increase in the notifications of measles was recorded in most areas; the largest rises were London 44 and Shropshire 37, and the only large decrease was Lancashire 45.

No further cases of dysentery were notified from Berkshire. Wallingford R.D., where 368 cases occurred in the preceding three weeks. A fresh outbreak of dysentery involving 13 persons was reported from Staffordshire, Willenhall R.D.; the only other large return was Lancashire 12.

For the tenth consecutive week a fall has been recorded in the number of notifications of poliomyelitis. The largest returns during the week were Lancashire 24 (Manchester C.B. 11), Kent 15, London 12, Middlesex 12, and Cheshire 11.

In Scotland increases were recorded in the notifications of scarlet fever 57, measles 33, and acute primary pneumonia 16. The only decrease of any size was one of 21 in the notifications of acute poliomyelitis. In Glasgow the notifications of pneumonia fell by 10 while the cases of scarlet fever notified rose by 27.

In Eire the chief features of the returns were an increase of 72 in the notifications of measles and a decrease of 15 in the cases of diarrhoea and enteritis. The increased incidence of measles was due to an outbreak in Wicklow, Bray U.D., where 78 cases were notified.

In Northern Ireland a decrease of 21 in the notifications of scarlet fever was recorded.

## Week Ending November 22

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,812, whooping-cough 1,183, diphtheria 220, measles 2,233, acute pneumonia 503, cerebrospinal fever 30, acute poliomyelitis 142, dysentery 141, paratyphoid 4, and typhoid 3.

Mental-health care in Scotland is to be associated as closely as possible with the health services generally and not developed independently in isolation, according to a circular published on Nov. 25 by the Department of Health for Scotland. Mental hospitals and institutions for mental defectives will in future be provided as part of the hospital service generally by the Secretary of State working through Regional Hospital Boards and Boards of Management. Existing hospitals and institutions will be transferred to the new Service next July on the appointed day. Either wards in existing poorhouses used for mental patients will be converted into mental hospitals, or the patients at present in them will be transferred as soon as possible to other hospitals. Responsibility for looking after lunatics living in private houses under guardianship, or boarded out from mental hospitals, will also be transferred from local authorities to the hospital service. The principal duties which local authorities will carry out in future will be the appointment of authorized officers who will be responsible for taking the necessary action to have a lunatic placed in a hospital, or under guardianship, where there is no relative or friend willing and able to take the necessary steps. Local authorities are given the new duty of providing suitable training and occupation for children not in institutions who have been reported by the education authority as unsuitable for a special school, whether certified as mental defectives or not, and also for all certified mental defectives over 16 who are not in institutions. Authorities have to submit by Feb. 28 for the Secretary of State's approval their proposals for carrying out their mental-health functions in the new Service. The circular urges authorities to frame their proposals in consultation with the hospital organization, the Executive Council responsible for general practitioner services, and any voluntary organizations concerned.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Prostigmin Test for Pregnancy

**Q.**—Would you describe the prostigmin test for pregnancy? What is its efficiency and what are its disadvantages?

**A.**—The test is used to distinguish between delayed onset of a menstrual period and early pregnancy. It entails the injection of 1 mg. prostigmin intramuscularly on three successive days. In the absence of pregnancy uterine bleeding occurs within 72 hours of the last injection, and sometimes so early that the second and third injections need not be given. No bleeding takes place if the patient is pregnant. The reliability of the test is difficult to assess, because it depends so much on a proper selection of cases. All women at the menopause, or with a history of previous menstrual irregularity, or with endocrine disease must be excluded, because a bleeding response is unlikely in such cases. With careful selection, and limitation of the test to healthy women of childbearing age with a normal menstrual history, it is 100% reliable when pregnancy is present and 90 to 95% accurate in the absence of pregnancy. The main disadvantages of the test are implicit in what is said above; a minor one is the occasional occurrence of transient giddiness and frequency of micturition following the injection of prostigmin.

### Uncontrolled Dicoumarol Therapy

**Q.**—Arising out of your annotation on dicoumarol (Oct. 25, p. 662), what advice could you give regarding the use of this drug by the G.P., since daily estimations of the prothrombin time are scarcely practicable in general practice?

**A.**—Dicoumarol should never be used unless daily estimations of the prothrombin time can be made, as it is impossible to predict the dose for any one patient. Failure to do this may result in fatal haemorrhage. Several instances are reported in the literature in which haemorrhage failing to respond to blood transfusion has followed uncontrolled dicoumarol therapy.

### Effect of Heat on Penicillin

**Q.**—What is the effect of heat on penicillin solution, and what is the rate of deterioration with increasing temperature? If it is highly thermostable, how, when it is injected, can it withstand the temperature of the body of a patient with a high fever?

**A.**—The rate of deterioration of penicillin in solution increases progressively from 0° to 100° C. and above. In the lower part of this range the process is so slow that the change would be unmeasurable over a period of less than several days: penicillin remains in the body only a few hours, and in any case the difference between normal body temperature—37.5° C.—and that attained in high fever—say 41° C.—is relatively small. The purer penicillin now produced is much more stable than the earlier product, and solutions can be heated to 60° C. without appreciable loss of activity; even boiling for short periods has little effect on it.

### Needles for Intramuscular Injection

**Q.**—What are the shortest needles for routine use in the intramuscular injection of fluids into the vastus externus and the deltoid?

**A.**—There are various factors which make a definite answer to this question somewhat difficult—for example, the variation in physical characteristics of different patients, and the quantity and consistency of the fluid to be injected. In general, it can be stated that short needles are more dangerous in that they are more likely to break; therefore if very short needles are used they should be of relatively wide bore. A good safe needle for ordinary purposes is one 1½ in. (3.75 cm.) long and 10 B.W. gauge.

### Hearing-aids in the Tropics

**Q.**—Can you tell me how to prevent damage to the crystal microphone amplifying valve in modern multi-valve hearing aids caused by the hot, humid climate of India? Is there any means of conditioning the entering air?

**A.**—The problem of the prevention of damage to hearing-aids by hot and humid climates is well recognized by most makers and is receiving their attention. The microphone crystals are frequently treated so as to be made moisture-proof. Unfortunately crystals so treated tend to become less efficient in high temperatures. Different crystals, such as potassium dihydrogen phosphate, are being tested in the hope of finding some which are more robust than those hitherto used. When a hearing aid fails owing to the effect of moisture it may be desiccated. This can be done by placing the entire instrument into an ordinary jar type of desiccator containing phosphorus pentoxide. This is probably a more satisfactory method than incorporating a pack of moisture-absorbing substance in the instrument.

### Medical Unfitness in a Witness

**Q.**—What is the accepted procedure for a doctor who is asked in a court of law to give the diagnosis in the case of a patient who should have attended as a witness? The patient I have in mind was suffering from asthma, and in my view was fit to travel but not to give evidence. The Court insisted on his appearance, and the consequent strain caused a relapse. Is it usual for the Court to overrule a medical opinion?

**A.**—A witness who is unable to attend court and give evidence should furnish a medical certificate of such unfitness, and if this is clear and unequivocal it will generally be accepted. In the case quoted the doctor might properly have certified that the witness was unfit to attend and give evidence; if called upon by the Court to state the diagnosis he is bound to do so. As it would be useless for the patient to attend unless he could give evidence, it was really irrelevant to say that he was fit only to attend. By admitting this the doctor left it open to the Court to infer (as it did) that the witness's disability was only of a minor degree, and that perhaps he was able to give evidence in spite of the doctor's opinion to the contrary. The Court is perfectly entitled to disregard evidence, medical or otherwise, which is not strong enough to carry conviction. If the patient had been certified as fit to give evidence at home this could have been arranged, such evidence being taken "on commission," thus saving the patient the fatigue of travelling to the court.

### Serum-bromide Estimation

**Q.**—What are regarded as the normal limits for a blood-bromide estimation? Apart from the oral administration of medicinal bromide, what conditions may cause a rise in the blood bromide?

**A.**—The method used in clinical laboratories for the estimation of serum bromide is not very accurate, and concentrations less than 25 mg. bromide per 100 ml. cannot be estimated. A normal serum bromide is therefore reported as "less than 25 mg. per 100 ml." The true serum bromide of healthy subjects is much less than this, and could be expressed in micrograms rather than milligrams per 100 ml. The writer has never heard of increases in serum bromide due to any cause other than the ingestion of sodium, potassium, or ammonium bromides; such ingestion might be medicinal or accidental.

### Repeated Hypnotism in a Child

**Q.**—The father of a boy of 2 hypnotizes the child almost daily in order to get him to sleep. The grandmother fears that harm to the child may result, and asks whether the practice could be stopped on the ground of cruelty. According to her the child is well behaved and sleeps well naturally. There seems to be no doubt about the hypnosis: the father is an electrician who has apparently acquired the knack. Can you tell me if harm to the child is likely to result?

**A.**—It is difficult to answer this question without knowing the nature of the alleged hypnosis. This may consist only in stroking movements, which the child finds pleasant and does not associate with their after-effects; on the other hand he

may be conscious of being dominated by his father against his will by an apparently magical method, and be seriously frightened by his own sense of helplessness against such omnipotence. At best, this practice is undesirable as establishing an unnatural relationship between father and son as well as a habit of artificially induced sleep, and it may well prejudice the child's emotional and social development. There seems to be no evidence of cruelty as such, but the situation is certainly fraught with danger to the child.

### Local Analgesia in Dentistry

**Q.**—What is the usual local analgesic used nowadays in dentistry? Recently, after local injections, patients have complained that the heart seemed to race and there was a feeling of imminent collapse. Why is this, and what can be done to prevent it?

**A.**—The most usual local analgesic for dental purposes is procaine. Adrenaline is incorporated in the solution in order to prolong the effect of the analgesic by localizing it. Large quantities of procaine can be injected without untoward effect. In dental surgery 1 to 2 ml. is the usual amount, so that the procaine itself is unlikely to be the cause of the condition described. The most common cause is the added adrenaline, which will of course give rise to such symptoms, particularly if some of the solution enters the blood stream through inadvertent puncture of a small vessel during the injection. Other substances are sometimes employed in place of the adrenaline as the vasoconstrictor, and it is claimed that unpleasant effects can thereby be avoided. Should the subject be particularly susceptible, procaine can of course be injected without a vasoconstrictor, though the analgesia is likely to be of shorter duration.

### NOTES AND COMMENTS

**Dupuytren's Contracture.**—Dr. KENNETH McFADYEAN (London, S.E.24) writes: Under "Any Questions?" (Nov. 8, p. 757) the treatment of Dupuytren's contracture is said to be either surgical or by administration of vitamin E. No mention is made of radium therapy in spite of the fact that during the last thirty years many cases have been treated at the Radium Institute, and doubtless elsewhere, with cure or improvement in many cases.

**Fissured Lip.**—Dr. L. S. WOODS (Albury, New South Wales) writes: In your reply (July 5, p. 41) no mention was made about dentures. An upper denture which allows the inner margin of the upper lip to overlap slightly on one or other side of the mouth may extend the moist surface of the lips in the corner of the mouth to the normally dry skin. This skin will become soft, and a crack or fissure may form. It is cured by adding to the upper denture, making it considerably thicker. This tightens up the slack, as it were, in the overhanging inner side of the upper lip, and the moist skin then remains dry.

**Removal of Superfluous Hair.**—Dr. CLARA M. WARREN (Kew Gardens) writes: In "Any Questions?" (Nov. 15, p. 805) there is a query about removal of superfluous hair. The answer is sharp and short, and in my opinion shows a complete disregard of all the factors which would induce a young woman to consult a doctor about hirsuties. It is unfeeling and unpractical. It is a mental tragedy for any woman to become conscious of excessive hair growth, particularly when it is on the face. Neuroses, feelings of inferiority and shame, and even threatened suicide are on record in cases of such handicapped women. The psychological shock if a woman is merely told to go away and use a razor can easily be imagined by an intelligent doctor. Advertisements and beauty culturists are probably responsible for the advice to use wax or depilatories. In elderly subjects these methods may be preferable, but in young people will finally lead to more extensive and thicker hirsuties. It is, of course, quite possible to pull out hairs, but as they grow again in from three to four weeks there will always be a consciousness that other people are looking at the regrowing bristles. Patients have been known to spend an hour a day for months pulling out hairs from the chin, and even then failing to keep the skin clear. It has generally been observed that shaving or pulling out hairs causes an increased stiffness and a stimulated growth, and after a few months the root of the hair becomes longer and the papilla situated deeper in the skin and more difficult to deal with when proper methods are used. In the majority of cases, the hirsute condition is familial and hereditary, and develops later than the spontaneous type, when the hairs first appear in the late teens and early twenties. Hirsuties as part of a generalized

excessive downiness is fairly common, but, although more difficult to treat, it can be helped. Exposure to ultra-violet light will make it worse. Endocrine factors play a very small part in common hirsuties. Apart from the recognized adrenal and pituitary conditions, dysfunction of the other endocrine glands is not marked. Clinicians have found that modern treatment with various endocrine substances has failed. Epilation by the use of x rays is avoided in this country, owing to the very real danger of atrophy and telangiectasia of the skin—a final result worse and more difficult to hit than the original condition.

Electrolysis is safe; and the direct current of 1-3 milliamperes required can be obtained from a battery, so that expensive apparatus is not necessary. A suitable handle and a very fine steel needle connected with the negative pole and a good light, are essential. The circuit should be completed through a moistened pad held by the patient and connected with the positive pole. No searing or marking should result from the method, and, although tedious in cases with many coarse hairs, it is satisfactory. From 40 to 60 hairs can be dealt with in a half-hour sitting. Bad cosmetic results occur with too strong a current, a stippling of the skin if the wrong pole is used for the needle.

For the type with coarse hair that has been frequently shaved plucked or otherwise stimulated a stronger current, such as produced by a diathermy apparatus, is most helpful. An ordinary portable medical diathermy can be used by a unipolar method, spark-gap being almost closed and the needle contained in a hole with a satisfactory make-and-break. Or an interruption can be obtained by means of a foot pedal. A make-and-break is essential as the flowing current will always be too much for the skin. A small amount allowed to pass in order to destroy the root of the hair takes only a fraction of a second, and starts at the point of the needle. Incidentally the needle must be kept quite clean, polished, or the current will coagulate the skin at the hair exit. From 100 to 120 hairs can be dealt with by diathermy in half an hour. No subsequent marking of the skin will result if carefully exercised and closely adjacent hairs are not treated at one sitting.

A certain amount of regrowth of hair apparently occurs in excessive cases of hirsuties during treatment, but this is not due to failure to kill the roots, but to a certain stimulating effect of the electric current on young hairs in the vicinity. These, however, can be treated at a subsequent sitting. Down or lanugo hairs do respond well to electrical treatment. The roots are short and to and the lanugo emerges through so fine an opening in the skin the passage of a needle will be difficult. This type is better in winter months, when there is no stimulating effect of sun and by treating any large coarse hairs among them considerable cosmetic improvement results. Ultra-short-wave diathermy apparatus can be used in a similar manner, and is preferred by operators. It is, on the whole, a more painful method than treatment with a medical diathermy apparatus, but it is less painful electrolysis on a mains set. The small milli-ampere required for electrolysis from a battery set makes this the least painful method.

**Mosquito Bites.**—Dr. LOUISE FRASER (Bournemouth) writes: recent issue under "Any Questions?" the treatment of mosquito bites was dealt with (Aug. 30, p. 357) and the statement made "once a mosquito bite has occurred there is little that can be done to alleviate the irritation," but some substances were recommended. These did not include the most efficacious remedy of i.e., a piece of soap, the commoner the better. This when rubbed on the bite acts almost like a charm. The irritation appears very quickly and the swelling subsides as one looks at it. The irritation usually returns in about twenty-four hours but virulently. Another application of the soap is as efficacious as the first. Having lived in a mosquito-infested country for many years and tried every advertised or recommended remedy with little success, the relief caused by this simple and handy remedy is one cause to dread the mosquito and its bite.

**Confidence Trick.**—Dr. A. O. F. ROSS (Liverpool) asks us to make it clear that he was not the Liverpool consultant referred to in case reported under this heading in our issue of Nov. 15 (p. 805).

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: "Westcott, London." ORIGINAL ARTICLES AND LETTERS for consideration should be sent to the SECRETARY, BRITISH MEDICAL JOURNAL, TAVISTOCK SQUARE, W.C.1. unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publisher, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1, on receipt of proofs. Overseas should indicate on MSS. if reprints are required, as proof is sent abroad.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 6 1947

## GENERAL MEDICAL COUNCIL.

### PRESIDENT'S ADDRESS

At the 172nd Session of the General Medical Council, opened on Nov. 25, the President, Sir Herbert Lightfoot Eason, delivered the following address:

I am pleased to note, as a rare occurrence, that since our last session there has been no change in the membership of the Council. No member has retired and no member has died. Two of our colleagues, Prof. W. J. Dilling and Sir Henry Wade, are prevented by illness from being with us, but both are, I am glad to say, making a satisfactory recovery.

I have to announce with regret the deaths of three former members of the Council. Dr. Cecil Wall, who died on June 19, represented the Society of Apothecaries of London from 1932 to 1939. As I said on his retirement, his quiet wisdom, keen interest in medical education, and love of tradition were of great value to the Council. He was a devoted member of the Society which he represented, and his history of the Society was the work of one who knew every detail, both abstract and concrete, of the Corporation and its Hall.

By the death of Sir Norman Bennett the dental profession has lost one of its most distinguished members. It is a matter of regret that the Council had the benefit of his services for only a comparatively short period from 1920 to 1921. He was, as many of the older members of the Council may remember, intimately connected with the preparation and passage into law of the Dentists Bill, 1921. The Act having been passed, Sir Norman resigned from the Council in November, 1921.

Mr. Joseph Ainsworth Woods, another member of the dental profession distinguished as a teacher and practitioner in Liverpool and as leader in the councils of the British Dental Association, was our colleague for an even shorter time in 1938-9. But he was with us long enough to make us feel confident in designating him to take part in the visitation of dental examinations which was abandoned on the outbreak of war; and he was one of those members of the Society of Friends who leave behind them a strong impression of personal rectitude wherever they go.

The King's Birthday Honours List in June included two names which none of us will have been surprised, and all of us will have been much gratified, to see. Prof. J. A. Gunn, though not a member of the Council, has long been their associate in the discharge of the indispensable duty laid upon them by the Medical Act, 1858, of causing the *British Pharmacopoeia* "to be published under their direction." An original member of the British Pharmacopoeia Commission since 1928 and Chairman since November, 1939, he not only shared in the labours of preparing the *Pharmacopoeia* of 1932 and the *Addendum* of 1936, but has borne, not merely by virtue of his office but also by reason of his enthusiasm, the main responsibility for the six wartime *Addenda* and for the new *Pharmacopoeia* whose publication is eagerly awaited in this country, elsewhere in the Commonwealth, and in the United States of America. It is not for us to seek to ascertain "the true weights and measures," in the words of the section of the Act of 1858 about the *British Pharmacopoeia*, by which the value of such long, arduous, and public-spirited service is weighed and measured side by side with the lifetime which this new Commander of the Most Excellent Order of the British Empire has devoted to teaching and research in the University of Oxford. But we may be allowed to bear witness to our belief that the honour bestowed upon him would not have been excessive had he

never laboured in any field but that with which we are as a Council officially familiar.

Dr. Wilfred Fish, Chairman of the Dental Board of the United Kingdom, who was made a Commander of the Order on the same occasion, has been our colleague in dental business since 1942, and I desire here only to speak of him in that capacity, not because I forget his distinguished record in teaching, investigation, and practice. I think the Council will wish me to seize the opportunity of conveying to him, with their congratulations, their sense of the high value of two aspects of his work as their collaborator. All who took part in the preparation of the evidence of the Council and of the Dental Board for the Interdepartmental Committee on Dentistry were, I am confident, impressed by his fairness and his ability to give and take in the paving of the way for a transfer of the dental business of the Council to the Board without destroying the salutary interest of the Council in the dental curriculum. His contribution to discussions, which were strenuous indeed but never degenerated into bitterness, marked him out as the destined successor of Prof. Edward Sheridan, a man difficult to succeed; and since he became Chairman of the Board in 1944 we have learned to admire his mastery of such business as the Board has to bring before the Council, and his forcible presentation of its views. These grounds alone would be enough to make us rejoice that the King has been pleased to honour him.

I am sure that the Council will also wish to congratulate Mr. J. J. Robertson on his appointment as Joint Parliamentary Under-Secretary of State for Scotland, and will also note with the greatest satisfaction that his promotion will not entail his resignation from this Council as a Crown Nominee. In the short time that Mr. Robertson has been a member of the Council he has endeared himself to all his colleagues, and has made valuable contributions to our work through his acute understanding of our problems and of our relation with the medical profession and the public.

It gives me much pleasure to introduce to the Council Mr. Cyril Pearce Harvey, B.C.L., who is sitting at my right hand as legal assessor at this session. As I intimated in June, steps will be taken in due course to ascertain the views of the Council on the question of the appointment of a successor to Mr. Bartley.

Since the last session I have received from the Home Office a letter calling attention to the number of cases in which it has been necessary recently for chief constables to ask the British Broadcasting Corporation to broadcast messages about thefts of dangerous drugs or other poisons from motor-cars left unattended by doctors. It is suggested by the Home Office that much valuable police time would be saved, and public safety increased, if all doctors would remove dangerous drugs or other poisons from their cars when they are unattended or, alternatively, would lock their cars. I hope that by giving such publicity as we can to this suggestion we shall ensure that members of the profession will exercise every possible care in the custody of dangerous drugs or other poisons which they may have to carry in motor-cars.

By the courtesy of the secretary of the organized profession of medicine in France the Council has been provided with a copy of the new statutes and regulations governing the organization and discipline of the profession there, and of the revised Code of Ethics laid down for its members. A précis of a translation of these documents will be circulated to members of the Council later. It is of interest to note that although the obligations of French practitioners in matters of professional conduct are set out in greater detail in the Code of

Ethics, they differ very little from the principles indicated in the Warning Notice of the Council. I am sure that the Council would desire me to convey to the French authorities its thanks for the communication of this interesting information.

The visitation of dental examinations has been extended to the subjects of General Medicine and General Surgery; and the Council has been most fortunate in securing the services as Visitors of Emeritus Professor Nixon, whose recent work as Inspector of Qualifying Examinations in Medicine is fresh in their memory, and of Mr. William Anderson, who completed the inspections of qualifying examinations in surgery after Mr. Collinson's death.

The Council will, I am sure, hear with great regret that owing to pressure of other Parliamentary business there is no certain prospect of a draft Bill Amending the Medical Acts being considered by Parliament during its present session. There is indeed no immediate hope of such legislation unless it proves to be within the scope of the phrase in the Gracious Speech from the Throne, "Other measures will be laid before you if time permits." This state of affairs is one which I know that the Council will view with grave concern. The short draft Bill submitted by the Council to the Government included not only important provisions based on recommendations of the Goodenough Committee, but also provisions giving practitioners a right of appeal to the Courts against penal erasure from the *Medical Register*; giving the Council statutory power, which they do not at present possess, to restore the names of practitioners to the *Register* after penal erasure; enabling the Council to take evidence on oath and to compel the attendances of witnesses by subpoena; and enlarging the direct representation of the profession on the Council. The enactment of such provisions as these would, I believe, commend itself alike to the profession and to the public.

The Medical Practitioners and Pharmacists Bill, whose primary purpose is to dispose finally of the problems raised by the temporary registration during the war of a large number of practitioners most of whom possess only qualifications granted in foreign countries, has been introduced in the House of Lords, was considered in Committee on Nov. 18, and is making further progress to-day. In addition to its main provision the Bill provides for the registration under certain conditions of practitioners who have served in His Majesty's Forces overseas, and of other qualified persons who have been permitted to enter, or to remain in, the United Kingdom in view of circumstances attributable to the war. The Special Committee of the Council on Legislation will be invited during the session to consider the terms of the Bill.

## WINTER SESSION

### Dental Cases

After consideration of the report and findings of the Dental Board the Council judged Albert Barrett, registered as of Yorkshire Street, Burnley, Dentists Act, 1921, to have been guilty of conduct infamous or disgraceful in a professional respect and directed the Registrar of the Dental Board to erase his name from the *Register*. The offence was that of carrying on and advertising a dental repair service for the purpose of obtaining patients. The Registrar was also directed to erase the name of Eric Hargreaves Swan, registered as of New Ferry, Birkenhead, Dentists Act, 1921, who had been proved to have been convicted at Birkenhead Quarter Sessions in January, 1947, of receiving certain goods knowing them to have been stolen and had been sentenced to five years' penal servitude, reduced by the Court of Criminal Appeal to four years'.

The name of Cyril Walter Bairstow was restored to the *Dentists' Register*.

## MEDICAL DISCIPLINARY INQUIRIES

### Cases Adjourned from Previous Sessions

The Council considered the case of Reuben Denny, registered as of Twyford Avenue, Acton, who had been found at a previous session to have been convicted in May, 1946, of driving a car while under the influence of drink. Dr. Denny attended and produced satisfactory testimonials, and the Council did not see fit to direct the Registrar to erase his name.

The next case was that of Bernard Maguire, registered as of Wilbraham Road, Chorlton, Manchester, who had previously been found to have been convicted in 1944 and in 1945 at the Manchester Police Court of being in charge of a motor-car while under the influence of drink. Dr. Maguire appeared and produced satisfactory evidence, and the Council did not see fit to direct the erasure of his name.

Dr. William Francis Hirsch Coulthard, registered as of Aspatia, Carlisle, against whom convictions in 1946 of being drunk and disorderly and of being drunk in charge of a motor-car had been proved, appeared and produced testimonials which were noted with satisfaction by the Council. Judgment in Dr. Coulthard's case had been postponed until November, 1948, but he had been required to make an interim appearance with testimonials at the present session.

Dr. William Allan, registered as of Sowerby Bridge, Yorkshire, who had been found to have been convicted in 1945 of obtaining £5 by means of false pretences, and judgment in whose case had been postponed by the Council, attended and produced certain testimonials. In the meantime a further conviction had been recorded. This was at Kingston-upon-Hull in October, 1947, of being under the influence of drink to such an extent as to be incapable of having control of the car of which he was in charge. Dr. Allan stated that he had been in hospital under treatment and was now much improved in health. The offence which led to this recent conviction was due to taking some alcohol while suffering severely from asthma. The Council postponed judgment further until November, 1948, but required Dr. Allan to appear before them in May, 1948, with testimonials as to his conduct in the interval.

### Offences Relating to Drugs

The Council considered the case of Joseph Anatole France Tobin, registered as of Windsor Road, Forest Gate, who was summoned on three convictions. In 1945 he had been convicted at Wealdstone of unlawfully failing to enter in a register particulars of quantities of dangerous drugs obtained by him. In November, 1944, he had been convicted at Welwyn of being in possession of certain drugs—"opoidine," "omnophon," and "alophon"—without being duly authorized (his authorization having been in the meantime withdrawn by the Home Office) and had been fined £2 in respect of each of seven offences. In September, 1946, he had been convicted at Whitehaven of having unlawfully given prescriptions for dangerous drugs and had been fined £5 in respect of each of seven offences. In all these cases he had pleaded guilty. The case before the Council had been postponed in June last owing to the state of Dr. Tobin's health.

Dr. Tobin now appeared, accompanied by his father, Dr. O. Watts Tobin.

Mr. Winterbotham, the Council's solicitor, said with regard to the first of these misdemeanours that it came to the notice of the police in 1942 that large purchases of morphine and other drugs were being made by the practitioner, who was accordingly interviewed and asked to produce his drugs register. He said that he could not find it and that in any case it was not a proper register. The Home Secretary, following this conviction, withdrew his authorization under the Dangerous Drugs Act. With regard to the second group of offences, Dr. Tobin had obtained certain drugs unlawfully in the course of his employment at Welwyn Garden City. Altogether 98 gr. (6.4 g.) of dangerous drugs had been wrongfully obtained. Dr. Tobin had admitted using for himself the drugs reported missing. With regard to the third group of offences no evidence was offered that in any of these cases he had obtained the drugs for himself or that they were not properly used. What had happened was that he went to Whitehaven as assistant to another doctor, who had suddenly to go into hospital, and Dr. Tobin whose authority to prescribe dangerous drugs had not been refused signed prescriptions for this doctor's patients.

Dr. Tobin, in a statement, said that he admitted the charges. On his wedding day in 1939 he had a serious motor-car accident involving a compound comminuted fracture of the humerus and a crushed and lacerated arm which remained infected for a very long time and necessitated a series of operations. He was in hospital for nine months, and was always in severe pain for which morphine was more or less continuously prescribed. After his return to work an intractable and painful sinus from the elbow-joint developed. For a long time, and smaller sinuses and sequestra developed. These were painful and he could carry on work only with occasional administrations of morphine. He became addicted to the use

through the necessity of having to work when he was not physically fit to do so. At the end of 1941 he joined the R.A.M.C. and served for 15 months. In 1943 he endeavoured to rid himself of the addiction and entered an institution for that purpose. Unfortunately, economic circumstances compelled him to return to work too soon. Twelve months ago he decided at all costs to get cured and went in for prolonged treatment, including seven months as a voluntary patient at Crichton Royal, and the authorities there now pronounced him fit. He felt now that he had completely overcome his weakness and he was anxious to rehabilitate himself. Dr. Tobin pointed out that the date of his last conviction was 15 months ago, and, without wishing to minimize the gravity of the offence, all the wrong that had been done had been directed against himself; he had not harmed anyone else. None of the patients for whom the drugs in the last series of offences were prescribed was an addict; they all received the drugs for proper reasons. He understood that the Home Office was prepared to renew authorization if he showed a clear record.

A letter was read from Dr. P. K. McCowan, the physician-superintendent of Crichton Royal, stating that Dr. Tobin had been treated for addiction to morphine and peralidine. He had co-operated in every way, and his response to treatment had been very satisfactory. He was now unaddicted to narcotic drugs and had increased psychiatric stability and greater sense of responsibility.

After the Council had deliberated in camera the President announced that the convictions had been proved, but the Council did not see fit to direct the Registrar to erase Dr. Tobin's name from the Register.

#### Misleading Certification

The Council considered the case of William Gray Hughes, registered as of Penrhyn Bay, Llandudno, who was summoned on the charge that in February and March of this year he gave five certificates stating that a Mr. Llewelyn Roberts was suffering from gastric (or duodenal) ulcer, with haemorrhage, that he was totally unfit for work, and that it was desirable that his son's Army leave should be extended in order that he might help to carry on his father's business. These certificates were given for the information of military officers to enable them to form a judgment whether compassionate leave of absence should be given to Rowlands junior, and were misleading in that they implied that throughout the period of six weeks the doctor was in regular personal attendance upon Mr. Rowlands and saw him on divers occasions, whereas in fact he did not personally attend or see him on more than one occasion (this was subsequently amended to two occasions) during the period. There were other charges as to certain implications in the certificates which the Council subsequently found not proved.

Dr. Gray Hughes attended and was accompanied by Mr. A. Lloyd-Jones, counsel, instructed by Jacques and Co., agents for D. Thomas, Williamson and Co., solicitors.

Mr. Gerald Howard, in outlining the case for the Council, said that at Deganwy, some five miles from where Dr. Hughes lived at Llandudno, there was a family named Rowlands. The father was assisted by his three sons in a log-selling business. One of the sons was on military service, but he was able in February and March of this year to remain at home on extended leave as a result of these certificates concerning his father's health. Dr. Hughes first came in contact with the Rowlands family when he was working as locum-tenent for Dr. E. R. L. Davies, who carried on his practice at Deganwy. In October, 1945, he was urgently sent for to see Mr. Rowlands, whom he found bleeding severely from the stomach. With care and treatment he slowly improved; the doctor warned him not to work any more but to leave the job to his sons, as any strain might induce another possibly fatal haemorrhage. In January, 1946, Dr. Davies came back to his practice after war service, and the next material date was Feb. 1, 1947, when Dr. Hughes certified that Rowlands was under his professional care suffering from haemorrhage from a large gastric ulcer, and asking the military authorities, for whom the certificate was intended, whether his son could be granted extended leave. It was fair to say that on this occasion Dr. Hughes did see Rowlands.

According to the evidence of a police constable who lived near the Rowlands, the father was out and about during the months of February and March, the period covered by these certificates, and to Mrs. Rowlands, she went to Dr. Hughes on each occasion and was not fit to carry on his employment. In a letter to the Council Dr. Hughes said, "Needless to say I feel very hurt and grieved that my efforts to get a simple-minded private out of trouble for over-staying his leave should have brought me before the notice of the G.M.C. . . . I entirely agree that I have been too lenient and sympathetic in this particular case, but, believe me, I felt sorry

for this lad, who in my opinion should never have been in the Army."

Mrs. Annie Rowlands gave confirmatory evidence as to obtaining the certificates from Dr. Hughes, and a police constable, Mr. Hobart Thomas, spoke of having seen Mr. Rowlands at work during the period covered by the certificates which stated that he was completely unfit for work, and was relying on the help of his son to carry on his business. He agreed, however, that Rowlands did suffer from stomach trouble.

Dr. Hughes, in evidence, said that he qualified in 1919, but had not practised on his own account since 1926. During the last twenty years he had helped other doctors and had served as a medical examiner; he was also interested in farming. He acted as locum-tenent for Dr. Davies, of Deganwy, from 1943 until 1946. Since February, 1946, he had not visited any patients, but he had attended patients who came to see him. He did not hold himself out to be a general practitioner for all purposes on his 15 days. He attended Rowlands in 1945 when he had severe gastric trouble. He urged him to go to hospital and he complied, but he refused and continued under his treatment for four or five weeks. At the beginning of February, 1947, Rowlands came to his house complaining of a recurrence of the trouble, and he gave him advice and treatment, and in a certificate stated that he was totally unfit for work. He saw him again on March 2, having in the meanwhile given two further certificates. On March 2 he certified, "By then (about a week) I hope to have got him all right again."

The first certificate was issued on March 1 and stated that Rowlands had not responded to treatment and rest as well as he thought he would have done. He gave this certificate to Mrs. Rowlands on her information that he had been visiting a great deal and that she and her sons had been up with him almost all night. He told the mother on that occasion that this must be the last certificate of the kind he could give, that it was a serious matter for a young soldier to overstay his leave, and that both she and he (the doctor) might find themselves in peril. He explained that he said this in order to impress Mrs. Rowlands, who did not seem to grasp the situation. He also explained that he wrote the letter already quoted because he was worried about the charge which brought him to the Council and failed entirely to see where he had gone wrong.

In cross-examination by Mr. Gerald Howard, he said that Dr. Davies had never been there people's doctor, but they came to him in the first instance because he was looking after Dr. Davies's practice. The treatment he prescribed was rest and diet, but he agreed that he did not take any trouble to find out whether his suggestions were being followed.

"Did you not think it your duty to see how this patient was going on before you gave another certificate?" "No, I knew that the condition would take an appreciable time to settle down."

"You say in one certificate that he is 'under my professional care.' Is that true?" "In a sense, yes."

"In what sense?" "In the sense that he had been to see me and I had given him instructions what to do."

"Why did you not go to see him?" "I felt that I knew enough about the case."

"Although, if your evidence is correct, he might have died?" "I knew that if he had another haemorrhage they would send for a nearer doctor instead of for me, five miles away."

"Why did you give the certificates?" "Because they came to see me."

"Do doctors give certificates because people come to see them?" "They cannot refuse if the people require them."

By Mr. Flood, a member of the Council: "How did you know this man had an actual haemorrhage?" "I saw it in 1945."

"I am speaking of 1947, when you certify that he is 'suffering from gastric haemorrhage from a large gastric ulcer.'" "Oh, from their description entirely."

"You considered his condition grave?" "Yes."

"Do you seriously tell us that you did not feel you had any duty to go and see him?" "I wanted him to go somewhere else."

"But you knew that he was not under any other doctor?" "Yes."

"And yet you did not go and see him?" "I wanted to wash my hands of this case altogether, and I also knew that if he had haemorrhage anything like he had in 1945 they would send for a nearer doctor."

"That is not the question. You were prepared to let things go on, because you wanted him to go to somebody else, although you knew that if he got another serious haemorrhage it might kill him?" "You can look at it that way."

"You left him there without medical attention?" "I would certainly have gone if they had sent for me."

"But he was left without attention?" "He was having rest and diet and a powder."

Mr. Lloyd-Jones pointed out that in only two of the five certificates it was stated that Dr. Hughes had seen and examined the patient; from the wording of the other certificates it could not be inferred that he had seen the patient at the time he issued them.

After deliberation *in camera* the Council found that the certificates had been issued, that they were given for subsequent use for an administrative purpose for the information of Army officers concerning compassionate leave of absence of a private, and that they were misleading in that they implied that Dr. Hughes was in regular personal attendance upon Mr. Rowlands in his professional capacity. The President continued:

"The Council regard your action in giving these certificates as a serious breach of the trust which Parliament has confided to members of the medical profession. The Council have listened to your explanation of the circumstances in which you have given the certificates, but they cannot accept the explanation as affording any excuse for your lacity in certifying. But they hope that the warning you have received by having been summoned to appear before them will be sufficient, and the Council have therefore not seen fit to direct the Registrar to erase your name from the *Medical Register*."

### Conviction

The Council considered the case of Kenneth Graham Wrigley, registered as of Somerset Road, Huddersfield, who appeared on the charge that in July last he was convicted at Huddersfield, after having pleaded guilty, of obtaining by false pretences on four occasions in February, March, and May, 1947, 25 tablets of omnopon, of the total value of 12s. On each of the four offences he had been fined £15.

Mr. Winterbotham, the solicitor to the Council, said that the tablets were obtained on National Health Insurance prescription forms. Inquiries showed that on several occasions the persons whose names were put on the prescription forms by the doctor were never supplied with the drug, and it was admitted by the doctor that in many cases the drugs had not been used for the patients themselves but for the doctor's wife, who was in great pain owing to severe spinal trouble which had developed after an accident, or for an aged housekeeper, who also needed omnopon for relief of pain. In addition to the four charges sixteen other similar offences were taken into account, and the stipendiary in imposing the fine said that this was a sad case owing to the domestic circumstances of Dr. Wrigley, but there had been a systematic course of fraud over a period of nine months and he could not pass it over without punishment.

Dr. D. J. Cartwright, solicitor, on behalf of Dr. Wrigley, said that this was indeed a distressing case owing to the long-continued illness of the doctor's wife, which caused him to have a distraught mind at the time these offences were committed. He put in testimonials from many persons in Huddersfield, including the medical officer of health and the social-welfare officer, and also a number of patients who spoke of Dr. Wrigley's devotion as a doctor.

The Council found that Dr. Wrigley had been convicted of the misdemeanours and took a serious view both of the offences themselves and the length of time they covered. But they postponed judgment for a period of twelve months, at the end of which time Dr. Wrigley would be required to appear again and bring forward testimonials from his professional brethren and other persons of standing in his locality who would be willing to testify as to his conduct in the interval.

### Re-election of President

Sir Herbert Eason, whose term of office as President of the Council ended at this session, was unanimously re-elected to the chair for the remainder of the term for which he had been made a member of the Council as representative of the University of London—namely, until Nov. 30, 1950.

In returning thanks he said that he was touched by this expression of renewed confidence. He was always apprehensive of that insidious disease known as senility, the symptoms of which were never apparent to the victim but always very evident to the observer, and he trusted to his colleagues on the Council, if they saw any sign of such falling off, to give him a friendly tap on the shoulder and he would dismiss himself to the obscure company of elder statesmen.

(To be concluded)

Dr. Cedric Baxter has been unanimously elected Chairman of the Liverpool Insurance Committee for the ensuing year. It is the first time that a practising medical man has been chairman. Dr. Cedric Baxter is a member of the Insurance Acts Committee, Vice-Chairman of the Local Panel Committee, and a Trustee of the National Insurance Defence Trust.

## PETROL RESTRICTIONS

### AGREEMENT WITH MINISTER OF FUEL AND POWER

It became clear some weeks ago that the Government's decision to discontinue the basic petrol ration would cause serious hardship to members of the medical profession. The registered medical practitioner is in a different position from other members of the community in that he is normally on call to his patients at all times of the day and night. Indeed, the doctor has become increasingly dependent upon his motor-car, and he is able to take a few hours' relaxation from his practice only because his car and essential medical equipment are immediately available to take him to an emergency call. Naturally the profession is expected to share with other sections of the community any hardships which arise from measures of retrenchment necessary in the national interest, but it is inequitable that doctors, because of their calling, should be denied some measure of social and recreational relaxation.

Representatives of the General Practice Committee have accordingly represented to the Minister of Fuel and Power that a doctor, when on reasonable call to his patients, should be permitted to use his car for any purpose. The Minister has recognized the special difficulties with which doctors are faced, though he has not been able to agree that doctors as a class should be subjected to no form of restriction in the use of petrol obtained on supplementary coupons. He has, however, agreed that if a doctor undertakes a social or recreational engagement and is at that time on call to his patients it would be reasonable for him to use his car in order that he might get to a case with the minimum of delay. In these circumstances, however, the doctor must be able to justify his action if challenged by the police. No doctor could justify the use of his car in circumstances where he had made alternative arrangements for his patients. Where a doctor using his car can show that he is on call to his patients and has taken steps to ensure that a message to which he can respond without delay can readily reach him it would, in the Ministry's view, be sufficient explanation that his car was being used in connexion with his professional duties.

Regional petroleum officers will be informed by the Ministry of these arrangements. It is understood that the police would not take any proceedings without prior consultation with the regional petroleum officer. It will be appreciated that the regional petroleum officer would not be in a position to express an opinion whether a doctor was in fact "on call" in any particular circumstances.

The Association has also learnt that regional petroleum officers have been instructed that petrol may be allowed to doctors for the purpose of attending meetings of the Association and other professional meetings in the locality. Where, for this purpose, the journeys involved are considerable the regional petroleum officer will consult the medical liaison officer as to the special importance of the meetings. The Ministry has agreed to look at any case where petrol has been refused for these purposes.

### "Doctor" Sign Available

Members who wish to affix a "Doctor" sign to the windscreen of their cars should know that suitable labels are now available and have been issued to honorary secretaries of Divisions for distribution to those practitioners who require them.

## DOMICILIARY LIFE-INSURANCE EXAMINATIONS ON THE "SHORT" FORM

Early in 1947 agreement was reached for the standardization of a "short" form of medical report in connexion with life insurance examination in respect of policies for amounts exceeding £300, at a fee of 10s. 6d. Details of this form were published in the *Supplement* (Sept. 20, p. 69). Subsequently a number of inquiries were received from Members regarding the adequacy of the fee in cases where the practitioner was required to visit the proposer for the purpose of conducting the examination. Negotiations on this question were resumed with the Industrial Life Offices' Association, which represents the majority of the companies and societies that use the form.

orm of report. Although this Association has felt itself unable to recommend to its members that an additional fee should be paid where domiciliary examinations are required, it has suggested certain procedure which it is thought will materially reduce the number of such examinations and to that extent relieve the doctor of the necessity of visiting the proposer.

This procedure, which has been accepted by the Association for a trial period of twelve months, and which will take effect as from Jan. 1, 1948, is as follows:

(a) That it shall be an instruction to agents and district managers of the Industrial Assurance Offices that wherever possible arrangements shall be made for the examination to take place at the practitioner's surgery.

(b) That, where this is impracticable, authority for the practitioner to be requested to make a domiciliary examination must be obtained from the head office or regional office of the company or society.

(c) Where such authority is obtained, mileage shall be paid at the rate of 1s. per mile or part of a mile, each way, beyond a radius of 2 miles from the practitioner's surgery.

## HEARD AT HEADQUARTERS

### The Association's Handbook

The *Annual Handbook* of the Association for 1947-8 in its blue coat is a little stouter than its immediate predecessors, though it does not come up in size to the considerable volumes which were issued before the war. But it is what it says it is, a handbook, sitting nicely into the pocket, and indispensable for those who deal in any official way, centrally or peripherally, with Association affairs. It contains the usual list of honorary secretaries—as many as 365, from the Isle of Wight to Shetland, from Malta to Tasmania, from Jamaica to Ceylon. A new section of the *Handbook* concerns public-relations activities, and a list is given of 50 Divisions which now have honorary public-relations secretaries and a similar number in which the honorary secretary himself does public-relations work. At first these public-relations secretaries were appointed to act in the medico-political field in order to see that the profession's case was properly presented, or false statements corrected, in their local press, but many of them are now serving as liaison officers concerning health matters and medical progress in general. This is as it should be. It would be unfortunate if it came to be thought that the only point at which the profession as such desired contact with public opinion was when some medico-political issue was involved. Another feature of the *Handbook* is a list of the more important decisions of the Representative Body, some of them dating back for forty years.

### "Occupational Health"

The Industrial Medicine Committee of the Association, under Dr. Vaughan Jones's chairmanship, has been tackling the question of definitions. In framing an answer to a questionnaire from the Industrial Health Advisory Committee the definition of occupational health and the choice between that term and industrial health arose, and it was resolved to seek some advice on this subject. At its meeting the other day the committee had before it a dozen replies from eminent authorities in social and industrial medicine. All but one of them preferred "occupational health" to "industrial health," since the latter was considered likely to lead to misinterpretations. After all, it is the job a man does rather than the particular industry within which that occupation falls that has most to do with his health. One medical authority opened up the further question whether it should not be "occupational medicine" rather than occupational health. Of the definitions of the field of "occupational health" Lord Horder's was the most succinct: "The study of the causes, effects, and preventive and curative treatment of diseases arising from occupations, including their associated environment."

### Health Centres

We hear of a proposal by the West London Branch of the Socialist Medical Association, in conjunction with the Hammersmith Trades Council, to draw up a plan for the siting of health centres in Hammersmith. Doctors in that area will scarcely need to be reminded that, if only because of the building

situation, any such plan is premature at the present time, and that so far as the profession is concerned any local consultation regarding health centres is a matter for a professional body of a representative character. The whole subject of group practice is being examined by a special committee of the Association.

## Correspondence

### Married Doctors and the Services

SIR.—The following may be of interest to young married doctors about to enter the Services; to others it is an example of the method by which remuneration for professional ability will be awarded to the doctors of the National Health Service. Married commissioned officers in the three Services until recently received a marriage allowance of £7s. 6d. per week, tax free. This allowance was stopped in the case of married officers under 25 years of age entering the Services after July 1946, and, after protest, was restored in part from Feb. 1 of this year. It was then decided that such officers could draw the marriage allowance allowed to the "other ranks"—viz. 45s. per week—and that from April 1 they could pay about half of it back again when marriage allowances became subject to income tax. Thus it is presumed that the young married doctor or professional man (these are the only people conscripted into a commission directly) can meet their professional social, and commissioned-rank commitments on the same marriage allowance as an "other rank" or on half the allowance of any other married officer.

By dint of hard work I qualified shortly after my 22nd birthday, and when I entered the R.A.F. I already had one son; yet I found that a colleague qualifying nine months later and only just married was to receive almost double my allowance as he was over 25 years. Age and rank (closely related before ability and commitments would seem to be the order of the day. Might I suggest that those of my colleagues in a similar position (and there are many) arrange that their M.P.s are acquainted with the facts—"the usual Service channels" are the usual waste of time.—I am, etc.,

CONSCRIPTED R.A.F.V.R.

\* The B.M.A. Armed Forces Committee drew the attention of the three Service Departments to this matter last May. Each Department replied that it was out of the question to give a higher rate of pay or marriage allowance to the man called up for national service than is payable to the comparable officer holding a permanent commission. The non-regular officer is, however, at present eligible for a war-service grant in certain circumstances where he suffers financial hardship as a result of his service with the Forces. On Oct. 30 Mr. Alexander, replying to a question asked on Oct. 24 by Sir Ernest Graham-Little, said that the remuneration of officers under 25 did not compare unfavourably with that of civilians of similar age and qualifications. It was not, therefore, proposed to alter the present arrangement.—Ed., B.M.J.

### Working Hours in the N.H.S.

SIR.—Let people argue for or against State medicine as they please, but at least let their arguments bear some relation to reality. Sir Ernest Graham-Little (Nov. 15, p. 117) raises two points.

(1) He assumes that immediately "free" medical attention is available there will be an enormous increase in work. There is no evidence whatever for this assumption. Patients will presumably remain the same. Those whom you cannot stop working will continue to work until they are half dead before going to their doctor, just as they do at present. Those whom you cannot start working will, as now, be constantly on the doorstep. Panel patients are just as considerate and courteous (or, if you like, just as inconsiderate and discourteous) as private patients, no more and no less. I once read a letter in a medical journal of 1911 when the controversy over the about-to-be-introduced panel system was at its height. The author stated dogmatically, just like Sir Ernest Graham-Little, that there would be an enormous increase in work. He went on to

After deliberation *in camera* the Council found that the certificates had been issued, that they were given for subsequent use for an administrative purpose for the information of Army officers concerning compassionate leave of absence of a private, and that they were misleading in that they implied that Dr. Hughes was in regular personal attendance upon Mr. Rowlands in his professional capacity. The President continued:

"The Council regard your action in giving these certificates as a serious breach of the trust which Parliament has confided to members of the medical profession. The Council have listened to your explanation of the circumstances in which you have given the certificates, but they cannot accept the explanation as affording any excuse for your laxity in certifying. But they hope that the warning you have received by having been summoned to appear before them will be sufficient, and the Council have therefore not seen fit to direct the Registrar to erase your name from the *Medical Register*."

### Conviction

The Council considered the case of Kenneth Graham Wrigley, registered as of Somerset Road, Huddersfield, who appeared on the charge that in July last he was convicted at Huddersfield, after having pleaded guilty, of obtaining by false pretences on four occasions in February, March, and May, 1947, 25 tablets of omnopon, of the total value of 12s. On each of the four offences he had been fined £15.

Mr. Winterbotham, the solicitor to the Council, said that the tablets were obtained on National Health Insurance prescription forms. Inquiries showed that on several occasions the persons whose names were put on the prescription forms by the doctor were never supplied with the drug, and it was admitted by the doctor that in many cases the drugs had not been used for the patients themselves but for the doctor's wife, who was in great pain owing to severe spinal trouble which had developed after an accident, or for an aged housekeeper, who also needed omnopon for relief of pain. In addition to the four charges sixteen other similar offences were taken into account, and the stipendiary in imposing the fine said that this was a sad case owing to the domestic circumstances of Dr. Wrigley, but there had been a systematic course of fraud over a period of nine months and he could not pass it over without punishment.

Dr. D. J. Cartwright, solicitor, on behalf of Dr. Wrigley, said that this was indeed a distressing case owing to the long-continued illness of the doctor's wife, which caused him to have a distraught mind at the time these offences were committed. He put in testimonials from many persons in Huddersfield, including the medical officer of health and the social-welfare officer, and also a number of patients who spoke of Dr. Wrigley's devotion as a doctor.

The Council found that Dr. Wrigley had been convicted of the misdemeanours and took a serious view both of the offences themselves and the length of time they covered. But they postponed judgment for a period of twelve months, at the end of which time Dr. Wrigley would be required to appear again and bring forward testimonials from his professional brethren and other persons of standing in his locality who would be willing to testify as to his conduct in the interval.

### Re-election of President

Sir Herbert Eason, whose term of office as President of the Council ended at this session, was unanimously re-elected to the chair for the remainder of the term for which he had been made a member of the Council as representative of the University of London—namely, until Nov. 30, 1950.

In returning thanks he said that he was touched by this expression of renewed confidence. He was always apprehensive of that insidious disease known as senility, the symptoms of which were never apparent to the victim but always very evident to the observer, and he trusted to his colleagues on the Council, if they saw any sign of such falling off, to give him a friendly tap on the shoulder and he would dismiss himself to the obscure company of elder statesmen.
